over-head', *n.* [*Accounting*]. Expenses that cannot be charged to any one part of a business, as rent, taxes, insurance, heating, lighting, etc.

own up, *v.* To confess.

pac'ifist (*păs'ĭ-fĭst*), *n.* In general, one who opposes war.

Pan-American Union. An organization, with headquarters in Washington, D.C., composed of the twenty-one American republics.

#pan'el (*păn'ĕl*), *n.* A section or segment of the wing of an airplane.

par'cel post. A service established in 1912 in connection with the mail service of the United States for the distribution of packages.

#park, *v.* To stop a vehicle outdoors and leave it. To stop while in a vehicle.

#pas'sive (*păs'ĭv*), *a.* [*Aeronautics*]. The condition of an aircraft when not under its own power or when without power of its own.

pas-to'ri-um (*păs-tō'rĭ-ŭm*), *n.* A term used in the South in Baptist churches in referring to the parsonage.

pen-tath'lon (*pĕn-tăth'lŏn*), *n.* An athletic contest in the modern Olympi d made up of a 1500 meter run, 200 meter run, a running broad jump, throwing the javelin, and throwing the discus.

pe-rip'-ter-y (*pĕ-rĭp'tĕr-ĭ*), *n.* In aeronautics, the region about an aircraft in which there are circular or whirling movements of the air.

Phi-la'the-a (*fĭ-lā'thē-ə*), *n.* A world wide organization of Bible classes composed of young women from all denominations.

pho'to-play (*fō'tō-plā'*), *n.* A play written for reproduction by a moving picture machine, or the reproduction itself.

#pi-lot (*pī'lŭt*). In aeronautics, one who flies or is qualified to fly an aircraft.

pi'lot balloon'. An unmanned balloon used to determine the direction of air currents.
pi-mien'to (*pē-myĕn'tō*), *n.* The sweet pepper from Spain used in stuffing olives; also the sweet pepper plant.
pinch hitter. In baseball, a player who goes in to bat in the place of another in an emergency.
#pit, *v.t.* To remove the stone, or pit, from fruit.
plain'-clothes'man. A detective or policeman who does not wear a uniform when on duty.
#plane (*plān*), *n.* An airplane. *Colloq.*
plas'mon (*plăz'mŏn*), *n.* A food made from skim milk.
plate circuit, *n.* In radio, the electric circuit that includes both plate and filament of an electric tube.
plate current, *n.* In radio, the current that flows between the plate and filament of an electron tube.
plate voltage, *n.* The voltage of a radio B battery.
platoon school. A school divided into two general divisions, so that one half may use rooms for study and ordinary class work while the other half are engaged in vocational, laboratory, gymnasium work, etc. The two divisions then reverse the use of facilities, thus using the equipment fully.
player piano, *n.* An automatic piano containing a mechanism that plays the instrument without pressing the keys.
plum'cot (*plŭm'kŏt*), *n.* A fruit resulting from crossing the plum and the apricot.
plus fours. A kind of loose baggy knickerbockers, worn especially in sports.
ply'wood' (*plī'wo͝od'*), *n.* Two or more layers of wood glued together with the grain of the various layers usually at right angles to each other in order to strengthen the wood and lessen warping.
po-di'a-trist (*pō-dī'ă-trĭst*), *n.* A person who takes care of the feet, a chiropodist.
po-di'a-try (*trĭ*), *n.* In medicine, the science and care of diseases of the feet.
pog'o-nip (*pŏg'ō nĭp*), *n.* A thick winter fog containing frozen particles, formed in deep mountain valleys. A term used in western United States.
poilu, *n.* A name for the French fighting man.
point-ed fox, *n.* The common red fox pelt, dyed and pointed, that is, with white hairs inserted, to resemble silver fox. A trade name used by furriers.
poi'ret' twill (*pwä'rĕ'*), *n.* A variety of woolen dress material woven to show a diagonal ribbed design.
polar front, *n.* A meteorological term, denoting the boundary between the cold air of polar regions and that of the warmer air of more temperate latitudes.
police dog. A dog trained to help the police, developed in Europe by crossing the domesticated dog with the wolf.
po-lice'wom'an, *n.* A woman who is in the police service; a woman assigned to police duties.
Pol'ly-an'na, *n.* A cheery optimist. The word is derived from the name of a young girl heroine of stories by Eleanor H. Porter. The word is also used as an adjective.
po-ma'to (*pō-mā'tō*), *n.* A plant produced by grafting tomato buds or shoots on potato plants. The fruit is tomatolike, usually eaten raw in salads.
#pork, *n.* American political slang for money or special favor given through political patronage rather than earned by actual service.
pork barrel, *n.* American political slang for money appropriated to public works for political ends rather than because the work in question is especially needed. These appropriations may also be in excess of actual amounts needed for the work.
post-op'er-a-tive, *a.* In surgery, a condition occurring after an operation.
post'war', *a.* After a war; especially, after the World War.
pow'er am'pli-fi-er, *n.* In radio, an amplifier that increases power.
pow'er boat or **pow'er-boat',** *n.* A motor boat, or boat propelled by an engine.
pow'er plant, *n.* An industrial building used to house a power-generating plant; or, engines and other parts that generate power in aircraft, boats and automobiles.
pre-can'cel, *v.t.* To cancel before use, usually applied to precancelled postage stamps.
pre-cool', *v.t.* To cool beforehand, as cooling of perishables such as fruits and flowers, before shipment.
preferen'tial vot'ing. A method of balloting by which the voter is permitted to indicate more than one choice for an office.
pre-par'ed-ness, *n.* The state of being in readiness, especially in regard to war.
pre'school, *n.* A school for children under regular school age, devoted mainly to social, educational and habit-forming training. The children are usually grouped by age; *a.* the period before a child reaches school age.
pres'sure cook'er, *n.* A cooker that is closed so tightly that the steam is retained and adds to the high temperature of the cooking contents.
pre'vo-ca'tion-al (*prē'vō-kā'shŭn-ăl*), *a.* Work or instruction in useful arts or manual training as given in schools that prepare students for the grades of the vocational schools.
pre-war', *a.* Before a war; especially, before the World War.
prick'ly heat (*prĭk'lĭ-*). A rash caused by extreme heat.
prof'it-eer' (*prŏf'ĭ-tēr'*), *n.* A person who makes an excessive profit, especially as in time of war.
Progres'sive par'ty. A political party under the leadership of Theodore Roosevelt, formally organized and named August 7, 1912.
#proj'ect, *n.* In educational work, a constructive task to be worked out by the student.
pro-jec'tor (*prō-jĕk'tĕr*), *n.* An appliance made to throw a picture on a screen by reflecting light.
pro'ton (*prō'tŏn*), *n.* The smallest unit of positive electricity.
protract'ed meet'ing. A religious meeting sometimes extending over several weeks.
pul'mo'tor (*pŭl'mō'tĕr*), *n.* A machine for producing artificial respiration in cases of asphyxiation, etc.
pulp'wood', *n.* Wood that is made into a pulp for manufacturing purposes, largely.
pure'bred', *a.* Bred from pure blood, usually used in relation to pedigreed live stock, but sometimes to denote purity in plants or seeds.
push'ball', *n.* A game played with an inflated ball six feet in diameter by two opposing groups of players, who attempt to push the ball across the field and under or over the bar that marks the opposing team's goal.
quan'tum (*kwŏn'tŭm*), *n.* [*Physics.*] The smallest amount of energy radiated or absorbed by matter. It varies as the frequency of the vibration associated with the ether wave.
quan'tum theory. The theory that energy exists in space in variable particles known as "quanta."
#quar'an-tine, *n.* Restraint of transportation of animals, goods or plants that may be carriers of disease, destructive insect life or other pest.
queen olive. A large olive of excellent quality grown near Seville, Spain, and pickled when green. Generally, any green pickled olive.
ques'tion'naire' (*kwĕs'chŭn'ār'*), *n.* A group of questions to be submitted to a person or persons.
race su'icide. Intentional restriction of child bearing; in general, any weakening of the vitality of a race.
ra'dial engine (*rā'dĭ-ăl*), *n.* [*Mach.*] An engine in which the cylinders are arranged like spokes in a wheel.
ra'di-o (*rā'dĭ-ō*), *a.* Usually referring to the radiant energy of electric waves, as used in radiotelegraphy or radiotelephony. *n.* radiotelegraphy or radiotelephony, radio message.
ra'di-o bea'con, *n.* A radio transmitting station that sends out special radio signals to serve as direction finders for those receiving them. Used largely to direct vessels at sea and aircraft.
ra'di-o-phone', *n.* Either a transmitting set for radiotelephony or a receiving set for that purpose.
ra'di-o-tron (*rā'dĭ-ō-trŏn*), *n.* An electron tube used in radios; a trademarked name.
ra'don (*rā'dŏn*), *n.* A gaseous element resembling argon.
#rag, *v.* [*Music.*] To play in syncopated time.
#rail'road (*rāl'rōd'*), *v.* To hasten; used in relation to bills in congress. *Colloq.*
range'find'er. In gunnery, an instrument for establishing the relative location and the distance from the gunner of anything to be shot at.
ray'on, *n.* An artificial silk made from cellulose by forcing it through small holes and drying the threads thus formed; also the cloth made from the fibers.
re'al-tor (*rē'ăl tŏr*), *n.* A real estate dealer who belongs to a local board having membership in the National Association of Real Estate Boards.
#re-call', *n.* The right of the people of a state upon petition of a sufficient number, to vote to remove a government official from office before he has completed his full term of service.
receiving set. In radio, the apparatus for receiving radio signals, messages and programs.
re'con-di'tion, *v.t.* To put into good condition some article that needs to be made over or have new parts supplied, the term being largely used for repaired second-hand automobiles.
red'-light' district. A part of a city in which there are many places of ill repute, some of which have red lights before them. *Colloq.*
#reg'is-ter, *v.t.* To convey an idea or feeling photographically, as an actor registers various emotions; also used in relation to voice reproduction in talking motion pictures.
rel'a-tiv'i-ty, *n.* A principle based on the assumption that our knowledge of velocity is relative, and leading to the conclusions that do not agree with previously accepted principles of mechanics. Also called the Einstein theory because first propounded by Albert Einstein.
#re-lease', *v.t.* To signify a specific date on which a play, phonograph record or printed matter, etc., may be published, put on sale, or given public exhibit; *n.* any play, book, record, etc., that has been given a release date.
re-vue' (*rē-vū'*), *n.* [Fr.] A musical comedy in which recent events and plays are imitated and somewhat burlesqued in an imitation of their outstanding scenes and actors.
rig'ger (*rĭg'gĕr*), *n.* A thin pointed brush made from the hair of sable, used by marine painters.
right of way. The customary or lawful right of traffic to take precedence over other traffic.
rŏ'bŏt (*rō'bŏt*), *n.* An efficient, automatic type of worker; an automaton. Karel Capek created the word to designate artificially created workmen that appeared in his play, *R. U. R.*
ro'de-o (*rō'dē-ō*), *n.* A market where cattle are collected; a public exhibition featuring the exciting incidents of a round-up, including roping and tying of cattle; riding and breaking wild horses, steer bulldogging, etc.
roll'er, *n.* A canary that is bred and trained to have a special roll, or trill, in its song.
#road'ster (*rōd'stĕr*), *n.* An open automobile seating two or three. It may have additional seats on running boards or in rear deck.
ro'to-gra-vure' (*-grā-vūr'*; *grā'vûr*), *n.* A kind of photogravure where etched cylindrical plates on a rotary press print pictures and text; also an illustration thus printed.
rough'neck, *n.* A rough or rowdy person. *Slang.*
rub'ber-stamp', *v.t.* To sign with a rubber stamp; a term for approving or disposing of a matter in routine fashion without giving it any thought. *Colloq.*
ruck'sack (*rŭk'săk*), *n.* A knapsack of canvas or other flexible material that is carried on the back, supported from straps over the shoulders.
rum'run'ner, *n.* A person who brings prohibited alcoholic liquor into a district or country, especially one who brings it for sale illegally.
sa'bo-tage' (*să'bō tăj'*), *n.* Deliberate damage done to an employer's property, whether goods, machinery, or plant; refusal to work, and interference with other workers.
safe'ty is'land, *n.* A space at the center of a street crossing which is raised or marked off for the protection of pedestrians in crossing
sas-tru'ga or **zas tru'ga,** *n.*, [*pl.*, **gi.**] Hard snow that has been blown by the wind into wavelike ridges with sharp, icy, overhanging edges. Occurs on level stretches in arctic and antarctic regions. These formations slope to windward and are sometimes several feet high.
#sat'urate, *v.* To completely or nearly completely charge with magnetism a mass of iron or steel, such as the field or armature core of a dynamo.
scamp'ing, *n.* A trade-union term, denoting inefficient work by an employee, or work done in excess of agreed rate of production in order to gain personal advancement at the expense of other workers.
scoff'law' (*skôf'lô'*). *n.* One who flouts the law, especially a prohibition-enforcement law.
#scout, *n.* A member of the Boy Scouts or Girl Scouts. In aeronautics, an airplane used for reconnoitering. It is usually armed with one machine gun and may be used also for a pursuit plane.
screen (*skrēn*), *v.* To throw upon a screen, as to screen a photoplay.
seal'ine' (*sēl'ĭn'*), *n.* A trade name for imitation seal fur, made from New Zealand rabbit pelts.
sea'plane, *n.* A hydro-airplane, made for use on the sea.
search'light', *n.* A strong light with reflector so adjusted as to throw its intense beams in any direction.
se-dan' (*sē-dăn'*), *n.* A closed car seating four or more, all in one compartment.
se'lec-tiv'i-ty. *n.* In radio, the ability of an apparatus to respond to impulses of the frequency to which it is adjusted or tuned and to give no response to other frequencies.
self-de-ter'mi-na'tion, *n.* In international law, the decision of people within a given district to decide for themselves its status, especially in regard to its form of government, independence or alliances.
self'-ser'vice, *a.* A type of store or other business in which the customers help themselves to what they wish, employees check up goods taken and patrons pay before leaving. Some establishments have a partial self-service, waiting on customers for certain items. Used largely in groceries, restaurants and some notion shops.
self-starter', *n.* An appliance using electricity, gas, etc., to start an engine, as an automobile engine, without cranking by hand.
#set, *n.* In moving pictures, the artificial setting for a scene of a photoplay.
sharp'shooter (*shärp'shōōt'ĕr*), *n.* A skilled marksman. In the United States Army, one making 60 per cent with slow fire at 800 and 1000 yards and with rapid fire at 500 yards.
#shed, *n.* See Hangar.
shell shock, *n.* A medical term for a number of nervous disorders usually caused by battle service and resulting from nervous strain or from concussion of exploding shells; *v.t.*, to cause shell shock.
shock absorb'er. A device designed to reduce the severity of the road shocks communicated from the running gear to the body of a vehicle, by regulating the action of the springs, especially by checking the violence of their recoil.
short story, or **short'-story.** A short prose story.
shrap'nel (*shrăp'nĕl*), *n.* A shell filled with small bullets and an explosive with fuse to discharge the shell in its flight.
side car. A small car attached to the side of a motorcycle.
#sign [off], *v.i.* In radio, to announce the end of a program or message.
sin'gle-sur'faced (*sŭr'fâst*), *a.* In aeronautics, referring to any part of the frame of an airplane covered on one side only.
sip'pi-o (*sĭp'ĭ-ō*), *n.* A game like bagatelle played with balls and cue.
#si'ren, *n.* A kind of automobile horn, producing sounds varying in pitch.
#skid, *n.* One of the two sledlike runners on some kinds of aircraft to simplify landing.
sky-scrap'er (*ski-scrăp'ĕr*), *n.* A very high building, hence any tall object. *Colloq.*
sky'man (*skī'măn*), *n.* An aviator. *Slang.*
sky pil'ot, *n.* See Pilot.

slacker, *n.* One who shirks responsibility, especially as in wartime by evading military service.
slea'zy (*slā'zĭ*), *a.* Said of cloth or other fabric that is very thin or loosely woven.
slick-er (*slĭk'ẽr*), *n.* A long waterproof coat.
slum'gum (*slŭm'gŭm'*), *n.* The mass of impurities remaining after the wax has been taken from the honeycomb.
#smock, *n.* A loose overgarment worn by artists, and recently especially by women in various occupations.
snide (*snīd*), *a.* Low, tricky. *Slang.*
#snipe (*snīp*), *v.* To take a long range shot at an enemy from concealment.
snow ban'ner, *n.* A stream of snow, sometimes miles in length, blown in the sky from a mountain peak.
#soar, *v.* In aeronautics, to move under impetus of the wind.
social service, *n.* Aid given the dependent, defective and delinquent classes, and those in temporary need in order to rehabilitate them as far as possible to normal living. Special workers are trained to render such service and usually work under organized charity supervisors, psychoanalysts, etc.
sock-dol'ager (*sŏk-dŏl'ă-jẽr*), *n.* Anything which firmly settles a matter. *Slang.*
sol'sette' (*swä'zĕt'*), *n.* A thin cotton fabric with plain weave that is mercerized to resemble China silk.
Sokol (*sō'kŏl*), *n.* [Bohem. *sokol*, a falcon.] A name applied to various Slavic gymnastic societies in Europe and in the United States which foster in their members the qualities of the falcon, such as strength of body, keenness and valor. The first Sokol had its origin in Prague in 1862. A member of one of these societies.
S O S. International wireless signal of distress.
son'der-class' (*zŏn'dẽr-klăs'*), *n.* A class of small yachts.
soon'er (*sōōn'ẽr*), *n.* One who occupies government land before it has been opened for homesteading by the government, thus gaining an unfair advantage over others; in general anyone who is unfair in such a way. *Slang.*
sour'dough, *n.* A prospector, trapper or other person leading an outdoor life in Alaska or northern Canada, so called from the piece of "sour dough" carried for bread making when camping. Also used to designate those who live the year round in these regions instead of leaving for the winter.
south'paw' (*south'pô'*), *n.* A left-handed pitcher.
so'viet' (*sō'vyĕt'*), *n.* [Russ.] A council and [*cap.*] in Russia the primary organs of government.
speed trap. A place along a motor road where motorists are trapped for speeding.
#spin, *n.* In aviation, letting an airplane descend while turning or spinning on its own axis.
#spir'it-u-al, *n.* A kind of religious song composed and sung by American Negroes, frequently pitched in a minor key.
spit ball, *n.* A ball pitched when the pitcher's fingers on one side of the ball are covered with saliva thus lessening the friction on that side and causing the ball to curve.
squeeze play, *n.* A play in baseball in which when there is not more than one out and a man is on third base, that man knows by signal that the batter is going to bunt a certain ball, and beginning to run when the pitcher lifts his arm to throw gains an advantage frequently enabling him to score.
#stat'ic (*stăt'ĭk*), *n.* In radio, an atmospheric disturbance.
sub-merg'i-ble (*-mûr'jĭ-b'l*), *n.* A submarine boat that may be entirely submerged.
sub-mers'i-ble (*-mûr'sĭ-b'l*), *n.* See Submergible.
sul'phite (*sŭl'fīt*), *n.* A spontaneous thinker. *Slang.*
sun'cup (*sŭn'kŭp'*), *n.* A variety of evening primrose bearing yellow flowers found in California.
su'per-man' (*sū'pẽr-măn'*), *n.* One so much stronger than others both physically and mentally that he is capable of dominating them; one sure to survive in the struggle for existence.
sur'tax', *n.* In the United States, a tax in addition to the normal income tax.

syn'di-cal-ism (*sĭn'dĭ-kăl-ĭz'm*), *n.* The idea of destroying political and social systems by a strike extending throughout all the land.
tag day. Any day on which those interested in a cause seek contributions to it, by petitioning people on the street, and give all those who contribute a tag to wear.
tail'-light', or **tail'-lamp',** *n.* A red light on the rear end of a vehicle.
tan'go (*tăn'gō*), *n.* A popular dance originating in Spain.
taxim'eter (*tăk-sĭm'ẽ-tẽr*), *n.* A mechanism used on public automobiles to keep passengers informed from moment to moment of the cost of the trip.
tear bomb, *n.* A bomb filled with chemicals which when they explode form a gas that blinds with tears anyone within its range.
tel'e-type (*tĕl'ẽ-tīp*), *n.* A typewriter that can be operated from a distance by electric signals. A trade marked name.
Ter'ri-to'ri-al-ism (*tẽr'ĭ-tō'rĭ-ăl-ĭz'm*), *n.* The movement among Jews towards a permanent home for the race, established in a territory where they may rule themselves.
Tex'as lea'guer, *n.* In baseball, a fly that falls between the areas usually covered by infielders and outfielders.
throm'bo-gen (*thrŏm'bō-jĕn*), *n.* In physiological chemistry, a substance thought to exist in the blood that gives rise to thrombin or fibrous ferment.
throw'back, *n.* Reversion to earlier type in race or ancestry, shown in form, thought, habit, etc. In motion pictures, the introduction between scenes of present time action of scenes that occurred at some earlier time.
tick'er, *n.* A telegraphic instrument that automatically prints on a narrow, continuous ribbon or tape. Usually used in referring to a stock ticker that records stock quotations.
Tom'my At'kins. A white British soldier.
tone poem, *n.* A musical composition for orchestra that attempts to express poetic images; a variant of the symphonic poem.
tong (*tŏng*), *n.* In the United States, a Chinese secret society.
ton'sil-lec'to-my (*tŏn'sĭ-lĕk'tŏ-mĭ*), *n.* Removal of the tonsils by surgical operation.
top grafting, *n.* A horticultural term for plant grafting, in which bud, shoot or other portion of a plant is grafted into the top portion of another plant.
#torpe'do, *n.* A torpedo-shaped automobile.
tour'ing car (*tōōr'ĭng*), *n.* An open car seating four or more with direct entrance to tonneau.
#track, *n.* In athletics, several competitive exercises, including foot races, weight throwing, hurdling, jumping, etc.; *a.* One who is a member of a track team is a track athlete.
trac'tor (*trăk'tŏr*), *n.* An automobile made to draw vehicles or machines, as a farm wagon or a plow.
trade acceptance, *n.* A bill of exchange covering the purchase price of merchandise drawn on the buyer by the seller, the former accepting by writing his name across the face of the bill.
trade agreement, *n.* An agreement between an employer and a trade-union to fix hours of labor, wages and working conditions.
#traf'fic, *n.* Vehicles and persons passing along a road, or vessels passing along a watercourse.
traf'fic man'a-ger, *n.* A superintendent in an industrial establishment who routes shipments, checks waybills and may also adjust claims.
trans'at-lan'tic, *n.* Somebody or something that is across the Atlantic; *a.* Used to modify a noun, as: transatlantic routes.
#trans-mis'sion, *n.* In radio, the passage of radio waves between transmitting and receiving stations; the act of transmitting.
tre'fa (*trā'fäh*), *a.* Ceremonially unclean according to Jewish law, usually applied to foods; the opposite of *kosher*, clean.
tric'o-lette', *n.* A cotton or rayon fabric woven like Jersey cloth.
try'out', *n.* A test or trial of a person to determine his efficiency, from the custom in sports of testing a contestant to establish in which class he belongs.
tu'la-rae'mi-a (*tōō'lă-rē'mĭ-ă*), *n.* A disease appearing in rodents, transmitted by insects, especially the deer fly, that manifests itself in man by a depressing fever that continues several weeks.
#tune, *v.*, **to tune in,** a radio expression for adjustment of receiving instruments for reception. —**to tune out,** to keep out undesired signals, messages, etc.
tur'key-trot (*tûr'kĭ-trŏt'*), *n.* A dance with feet wide apart and eccentric rise and drop of the feet.
turn'o-ver, *n.* A completed merchandise transaction of purchase, sale and replacement of stock, usually in relation to a given period of time, business success depending on a certain rate of turnover that varies according to the type of goods handled, etc. Also, the labor turnover, or number of new persons hired within a given period to replace others who are dropped or leave, this number being taken in proportion to the entire force.
twi'light sleep, *n.* A method of painless child birth by the use of two drugs, scopolamin and morphine. The success of the method is in dispute by members of the medical profession.
#twist, *v.t.* In life insurance, persuading a person to drop a life insurance policy already in force and to take out a new one in its place.
typh-lol'o-gy (*tĭf-lŏl'ô-jĭ*), *n.* Scientific study of the causes and effects of blindness.
typh' o ma la'ri a (*tĭ'fō mā lā'rĭ ā*), *n.* A disease supposed to be malarial in origin but exhibiting typhoid symptoms.
ty'po-script, *n.* Typewritten matter.
u-'kule'le (*ū'kōō-lā'lē*). A small four-stringed guitar, originally from Hawaii.
un'der-sea', *a.* Something that is, or is going on, beneath the surface of the sea; as: under-sea photography.
un'der-slung (*ŭn'dẽr-slŭng'*), *a.* Said of an automobile so constructed that the frame of the chassis is below the axles. Underhung.
un-scram'ble, *v.t.* To separate a thing into its original parts, a phrase ascribed to J. P. Morgan, that "you can't unscramble eggs," when attempts were made to dissolve certain trusts.
#u-til'i-ty, *n.* A shortened form of **public utility,** a business that supplies the public with some commodity or service, such as electric light, gas, water, etc.
vacuum bottle. A bottle made on the Dewar principle, for keeping the contents either cold or hot.
#vamp, *n.* A vampire; *v.i.*, to act the part of a vampire, to beguile. *Slang.*
#vampire, *n.* A figurative expression for a seductive person, usually a woman who lives by preying on others.
#van'i-ty, n. A small bag or box fitted with toilet articles, usually powder and rouge.
vel'ou-tine' (*vĕl'ōō tēn'*), *n.* A velvet-finish corded fabric of somewhat lighter weight than corduroy.
ve-ne'tian, *n.* A type of twilled cotton fabric of fairly light weight.
ver'ni-er (*vûr'nĭ ẽr*), *n.* In radio, a small auxiliary part that is used with a main device in order to attain sensitive adjustment.
vest'ee' (*vĕs tē*), *n.* A garment resembling the front of a vest, but without sleeves or armholes, worn to fill in the front of a dress or riding habit.
#vic-to'ri-a, *a.* An automobile touring car with calash top, usually extending only over the rear seat.
Victo'ria Cross. A Maltese cross given for bravery first by Queen Victoria in 1857.
violet rays, *n.* The shortest rays of the spectrum that are visible to mankind, sometimes incorrectly applied also to the therapeutic ultra-violet rays of the spectrum.
vi'ta-min, also **vi'ta-mine,** *n.* A constituent found in many foods, the absence of which in food causes a weakening of bodily tissues, resulting in disease such as beri-beri, pellagra, scurvy, etc. Usually food containing vitamins will cure the disease previously caused by their absence.
vod'ka (*vŏd'kă*), *n.* A Russian intoxicating liquor made usually from rye as a government monopoly, prohibited at the beginning of the World War.
vol'plane (*vŏl'plān*), *v.* To glide in an aircraft.
Volstead Act. An act of Congress providing for enforcement of the eighteenth or Prohibition Amendment to the Constitution.
walk'a-way', *n.* An easily won contest, especially when the winner of a race lessens his speed at the finish because other contestants are so far behind.
wan'gle, *v.t.* Adjusting in makeshift manner; swindle, deceive.
Washington Conference. An armaments limitation conference held at Washington, D. C., from Nov. 12, 1921, to Feb. 6, 1922, in which the United States and eight other nations participated.
Wasserman test. A test for syphilis.
#wave, *n.* A nation-wide movement of whatever kind, as the farm relief wave.
weed'less, *a.* A term applied to a kind of propeller for a motor boat, so constructed that it does not gather weeds.
wheeze, *n.* A joke or tale so old that it is familiar to those who hear it. *Slang.*
white' col'lar, *a.* People whose work is of such nature that they can wear white collars while at work; specifically, salespeople and clerical workers in contrast with manual laborers.
white gold, *n.* Gold alloyed with nickel, zinc, iron, silver or other metal that will produce a whitish alloy.
white plague. Tuberculosis, usually of the lungs.
white slave. A woman detained against her wishes and forced into unwilling prostitution.
wie'ner-wurst' (*vē'nûr wōōrst*), *n.* A beef sausage, or beef and pork sausage, made in a link about a half-inch in diameter.
#wild'fire, *n.* A quick-spreading disease of the tobacco plant that appears in brown spots on the leaves. These spread or drop out, spoiling the leaves for use.
wind'shield, *n.* A shield of transparent material, usually glass, set in a frame to protect the occupants of an automobile or open-cockpit airplane from wind and rain.
#wire, *n.* A telegram. *Colloq.*
World Court. The Permanent Court of International Justice; also a proposed court similar to this one, but separate from the League of Nations.
World War. The war between the nations that began July 28, 1914, and ended with the armistice of Nov. 11, 1918. The peace treaty [Treaty of Versailles] was signed June 28, 1919.
wrist watch, *n.* A small watch that is worn on a bracelet, ribbon, strap or cord around the wrist.
xy-lot'o-my (*zī lŏt'ŏ mĭ*), *n.* The cutting of sections of wood by a microtome in preparation for their examination under a microscope.
#yaw, *v.t., v.i.* In aeronautics, to turn an airplane from its line of flight by an angular motion about its vertical axis.
yer'ga (*yûr'gă*), *n.* A coarse woolen material. Its chief use is for horse blankets.
yu'an (*yōō'ăn*), *n.* A silver coin that has been the monetary unit of the Chinese Republic since January, 1914; worth about .464 cent in coin of the United States.
#ze'ro, or **zero hour,** *n.* In British military science the zero hour is the one at which a previously planned movement starts, all other movements being planned for a certain length of time before or after the zero hour. Often used figuratively. In American military regulations, **H hour** is the regular term.
zirc'ite, or **zirk'ite** (*zûr'kīt*), *n.* Natural zirconium oxide, used in making bricks for furnace linings because of its reflection of heat.
zlo'ty (*zlō'tĭ*), *n., pl. zlotys.* The gold monetary unit of Poland, worth about 19.3 cents in American money; also a silver coin of the same value.
#zone, *n.* Any one of the circular areas about a shipping point designated by the Parcel Post Act of 1912. *v.t.*, city planning, to partition a town or city by ordinance into sections that are limited to certain heights, uses or types of buildings, such as residence, business, manufacturing establishments. From this arise the names: zoning commission, zoning ordinances, etc.

BOOK X

MATHEMATICS

The Magic of Number.—Number has always been a mysterious thing, endowed with magic powers. From ancient times till now, philosophers no less than the masses of men have attributed to them faculties to affect the life and fate of human beings favorably or disastrously. Superstitions attach to certain numbers even in our present enlightened times. The number Three has always been considered as particularly sacred. This may be due to the fact that, in primitive number conception, it was an enormous step for humans to distinguish "three" from "many".

To our modern conception this may seem preposterous. But it is not. To us, the concept "three" is so elementary, so obvious, that we can hardly believe there was a time when it was as hazy to all as to us is a million. But do we not even now speak of a man who appears stupid as one "who cannot count three?" The origin of languages shows how these concepts developed. We have the "singular" number of nouns, meaning one object; this is a clear concept. What was beyond "one" was hazy, undefined, "many", expressed by the "plural". In some languages, the step from "one" to "two" is preserved; the classic example is the ancient Greek language which has a "dual" form of nouns, denoting "two" objects of the same kind. What was beyond "two", was "many", an indefinite number. Numerals, to denote definite larger numbers, developed slowly. Definiteness in number conception has been a painfully laborious acquisition of the human race. The science of number was the first exact science which had to be evolved before any other of the exact sciences, like physics, chemistry, astronomy, etc., could be created—but it was only in the time of classic Greece that this fundamental step was accomplished.

Number and the Child.—Shall we wonder, then, that our children are slow in developing a real understanding of number relations, of quantity, of precise statements? Children, in their mental growth from infancy to maturity, follow in a measure the steps the race has taken in its evolution from primitive culture to modern civilization, and we can understand a child's difficulties better if we take this fact into careful consideration.

The child is subject to the same process of evolving "precise cognition" from the initial hazy concepts which has been followed by the race. To proceed from a clear concept of unity, of "one" object, to that of more than one, is the first step. To realize duality, that is to say, "two" objects, either like, or different objects, is a very fundamental step; and to proceed from that to the identification of the trinity, or three-ness, is the beginning of real number conception.

Methods of Developing Number Concepts.—Just as the race has used primitive methods of achieving results in this process, the child needs primitive devices to conquer the world of number. It is a very slow process, let us remember. And we must lay the earliest foundations most carefully, never be impatient, or try to follow a short cut, or omit an essential step. We must rather follow the lead of the child, not force him along the way which seems to be easy for us. It may surprise us at times to discover that it is not the child's method (neither has it been the method of the race) to follow the logical path, to do the simple and obvious thing. He treads devious paths, backward and forward, sideways and curving around, trying now this and now that strange device, until finally he finds the solution of his problem—not at all where we ourselves would have been looking for it.

We may therefore give him an opportunity, or rather plenty of opportunities, to occupy himself in a primitive manner, using his fingers, natural objects, like pebbles, leaves, acorns, etc., or beads, and strings and knots, and what not, to gradually evolve in his mind ideas which will give definite arithmetical and geometrical outlines to the world of knowledge—remembering that this world of his is very small at first.

Home Training in Number.—The suggestions given here are not intended for the teacher, although perhaps many a teacher may learn some facts and tricks of procedure from what is presented here. But we have primarily the parent in mind, and wish to give him, or her (for it may be mostly the mother whose share this training will be) advice in the matter of practical methods for developing the child's conception of number relations.

The suggestions refer *first*, to the preschool period of the child—in fact, to the entire period of the child from birth to the kindergarten age. *Secondly*, to the kindergarten period itself. Whether the mother has the opportunity of sending her child to a good kindergarten or not, it will be advantageous for her to understand the needs of this period, and the "gifts", "occupations", and games which are employed in the kindergarten to awaken an appreciation of number and form, at least in a measure. *Thirdly*, the suggestions include the period of primary school work. Here a special caution is needed.

School methods, and school grading, are not ideal; they are adapted to the needs of great numbers of children of an average mental type; they are dependent upon the understanding and skill of teachers who are often young and inexperienced, and have no intimate knowledge of child needs. Again, their opportunities are limited to school hours and school organization. The parent at home has almost unlimited opportunities, in play and work, on walks and in heart-to-heart talks, and in a thousand other ways such as the routine of the home affords, to approach the child's number problems. In the home, perhaps, more can be accomplished in giving the child a thorough grounding in the true principles of number conception than in the school itself.

But we must understand that the process cannot be so logically graded as the school endeavors to do. To illustrate this, the author will tell how one little boy made his start in number.

This little boy, now between seven and eight, has not gone to school yet, for certain reasons. He is in many ways an exceptional boy, and brought up somewhat differently from the ordinary type of boys who attend school in the regular way.

Although even now he has only begun to write his figures, he has learned a great deal of arithmetic by absorption and observation. He began, as all children do, as we shall see later, by counting. At first, the sequence of number names was not clear in his memory, and he told them in confused order. When he had learned to say the big number names, like one hundred or so, even when he was quite young, he took great delight in mixing them into his speech. He had a hundred marbles, or five hundred and six blocks. A few hundred more or less made no difference. These words were substitutes for "many". He acted in this respect as some ancient peoples did, like the Hindoos, who talked in their religious stories and mythologies of hundreds of thousands and even millions of years as if they were bean bags.

Finally the little boy settled down to hard facts. In a general way, he proceeded from simple numbers, the larger ones remaining hazy quantities to him for a while. He began by distinguishing "few" and "many". Then he knew clearly about two and three things. After this, his progress was accelerated. Indeed, he was not always quite sure about the difference between four and five things or so, but he worked hard. He usually dealt with concrete things, the number of his playthings, or of people, but did not altogether tie himself down that way. He arrived at larger numbers by addition, adding one or two or three at a time. But he defied the schoolmaster's theory that he should not proceed to four until he had exhausted the possibilities of three; or to six, until he had studied five thoroughly. He jumped. He was an arithmetical acrobat. He turned around and went backwards; he twisted and wound and unwound things so that you could not follow him. No set rule of method would have reached him. He was a law unto himself.

This is one of the reasons why in the following pages we will not offer a strictly systematized course of procedure. We shall make constant connections and associations, and will suggest to the parent using these suggestions that they will be guided rather by their children's interest and individual method than by anything we or anybody else can offer in the matter of "proper sequence".

The little boy we are speaking of taught himself multiplication and division by such questions as: "Isn't two threes six?" "Isn't twelve two times six?" And so on. Subtraction is even now a poser to him, and it is a strange fact that it is for most children a curious stumbling-block. But he has mastered, all by himself, without any planned out teaching, such quantities

as the dozen, the dollar, and their divisions, and has a very fair conception of mathematical relations, usually expected only of much older children. But he will disappoint you at times, seeming to have lost all he had known, and beginning all over again. Soon after, he will make another big jump and astound you by a bit of calculation; going to the stores, making the right change in buying different things, selecting bargains, and telling the storekeeper very plainly what is in his mind if there seems to be anything wrong. Recently, on a visit to the seashore, he went alone to take his breakfast at a restaurant, paid for it, and left a tip for the waitress. What school method would keep up with such a child's development?

Earliest Number Training.—Strange as it may seem, but training in number conception begins in the cradle, or on the mother's lap.

The fundamental operations upon which all other, more and more complex ideas of arithmetical relations are based, are:

(1) *Counting* and *tallying.*

(2) Concepts of *space.*

Counting begins with the earliest *finger and toe games* which the mother plays with her child. "This little pig went to market," etc., introduces a primitive counting, tallying the equal number of toes on each foot. "This is the thumb," etc., brings the fingers into play, with the same tallying process.

The development of the consciousness of fingers and toes is of very great importance. That there are five toes to be counted on each foot, and five fingers (thumb included) on each hand, is the basis of our decimal system of computation. One hand, or one foot, equals five, in ancient or primitive methods of counting. Two hands, or both feet, represent the ten; "the whole body" (both hands and both feet) is twenty. Even the divisions of the fingers play their part in early measurement: one link, or joint, representing an ancient inch. The term "digits", still used in denoting the numbers from one to ten, means the ten fingers. It is therefore of significance not to speak of the thumb as not being a "finger" as is customary in some places. The thumb has its place in this system of computation.

Finger reckoning is as ancient as the race, one might say. We may well use it today in the development of the number concept with young children. It is replaced by more or less symbolic forms through the introduction of *beads, knotted cords,* etc., of which we shall speak presently; the *abacus,* or *number frame,* is one of the more systematic forms of mechanical contrivances to represent finger reckoning. The Chinese and Japanese employ it to this day in their daily tasks.

Mothers will do well to become acquainted with Miss Emilie Poulsson's admirable *Finger Plays,* intended for the use in the kindergarten and the home. Much of the material suggested by Miss Poulsson can be used by the mother with her baby on her lap.

Before the concept of number in its precise value is formed by the child, it has the realization of "larger" and "smaller", which later assumes the distinction between "more" or "less". If you place before the child two different heaps of beads, or sticks, and ask for the larger heap, the child will soon select the one containing more objects, without at once understanding that the larger heap also contains "more" beans or sticks than the smaller. The child may develop a rather high degree of discrimination between "larger" and "smaller", or "equal" heaps, and be able to detect small differences, without knowing that it has begun to have a dawning conception of real "quantity". We may not be justified in ascribing to a cat, or a dog, the faculty of counting their litter, but the cat mother and the dog mother know whether all their young ones are there or not. This knowledge is based, apparently upon that same faculty of making nice discriminations of mass relations, taking their litter as a "heap", and discovering a diminishing of that heap, which the child develops before he learns really to count.

Even at this period of hazy number conception, when there is mainly a concept of larger or smaller space, or body, it is essential to hold the child to *tallying.* Tallying means comparison. Comparison establishes the relation of one quantity to another. On this idea of relationship, of comparison, of tallying, all number work is based. Even when we measure the stars, or the relativity of the universe, with Professor Einstein, we are dealing with comparative values; otherwise these figures would have no meaning to us.

Thus, let the child compare the "larger" and the "smaller" things or masses, the "more" or "less" of objects, constantly. This is no strain to the child at all; quite the contrary. It is an innate desire of the normal child to keep on counting and tallying.

Real counting will begin also quite early; only one must not be discouraged if the child makes slow progress at first in remembering the *number names* and placing them in the right sequence. Confusion in names does not necessarily signify confusion in actual perception or count; just as little as confusion in color names means confusion in color perception.

As said before, the mastering of the first three precise counts, one, two, three, requires the longest time; it is fundamental. Twos, that is, pairs, can be readily found in the child's closest perceptions: he has two hands, two feet, two ears, two eyes, two lips, two rows of teeth. He perceives the same fact in others. Pairs are also observable in objects which, like garments, are balanced in arrangement; again, there are always two ends to a stick; two sides, as to a plate. And so on. All these things can be utilized to impress the idea of two, and of pairing. The idea of pairing introduces also the first glimmer of arrangement, or harmony, of balance and symmetry, and later on of the fundamental operations.

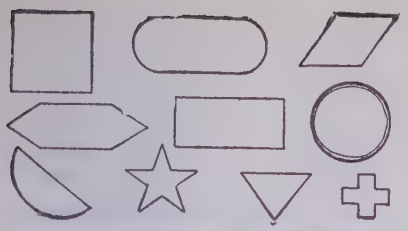
The transition to three and then to four is much more difficult. Three is the first odd number after one, and has no seeming relationship to the outside world or to other quantities until later developments are reached. That is why its conception is so difficult, why it has been held in awe by millions of generations of human beings. It is best understood as a combination of the first two concepts, the one and the two. It may be introduced by contrast: the child has two eyes, and two ears, and two hands, but only one mouth, one nose. Then we have the story of Little One-Eye, Little Two-Eyes, and Little Three-Eyes, which will help.

Further development can be well connected with many interesting occupations and games.

But even before they are introduced, counting, plain and simple, should be fostered. That is to say, the child should learn the number NAMES in sequence. This is not irrational, for the reason that the child delights in this very process, and that this early age is the period in which the memory is strong for words. It is a learning of names.

So let the child count, and count again, even if he does not connect a definite number concept with the names. But do not forget to have him count *things* right along with the drill in memorizing the names.

Let him count anything and everything: his playthings, the steps he takes up and down stairs, pebbles, rings, cutlery and dishes on the table, the persons in the room, and what not. The whole world should be embraced in this counting process, as far as his little mind can fathom it.

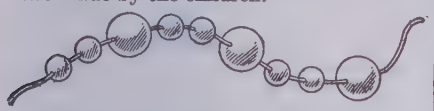


Special Exercises and Occupations.—How little reliance can be placed upon a young child's capacity for remembering and understanding number, may be illustrated by one of the early attempts to measure intelligence. In the original "Binet" Scale, a child of three is expected to be able to repeat but two number names after hearing them once, like 6–4; a child of four is put down as being able to repeat five numerals. A child of five is expected to count only 4 pennies; one of seven, to tell how many fingers he has on one hand, on both hands; or to count 13 pennies. These are very low estimates, indeed, and it will be found that normal children can do vastly more if properly trained.

We shall suggest a number of exercises, widely used in kindergartens and schools, which can be fitly employed by parents long before the child enters kindergarten, or certainly during the early kindergarten age.

The use of *Building Blocks* can be introduced early. The child likes building. Use large size blocks instead of the ordinary type; but even an ordinary box will supply occupation. First let the child play at will, in his own imaginative and constructive way. Then let him count the blocks, arrange them in twos, threes, etc. If you use colored blocks, a great variety of exercises can be obtained.

A large *Peg-Board* with white and colored pegs will offer much delight and exercise in arrangement and counting. The child can make borders, single and double, counting the pegs; diagonals, rows of two or three each, etc. With the colored pegs, you can arrange designs and borders, as well as rows, using twos, threes, fours, etc., of blue, red, yellow, and the other colors alternating.

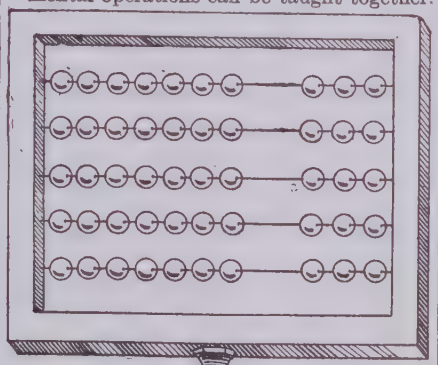


The peg-board has this advantage over sticklaying that it gives the child a definite place for each peg. The muscular coordination required for fitting a peg in its hole is less minute than that which is needed in laying light sticks in rows with any degree of accuracy. Yet, even the use of the peg-board may require, with some children, a preparation. This is afforded by the so-called *Form-Boards.* Some of these are intended merely to test children as to their conception of form, that is to say, of geometrical figures. Here is the picture of one which was first introduced for testing imbeciles, or suspected imbeciles, but which has its special value outside of this; it will teach a young child some of the fundamental forms. The board in which the figures are to be fitted is carved out in corresponding grooves.

There are other form-boards, used for a variety of teaching and testing purposes; but we are here dealing with number teaching only we need not specify them. Some of the Montessori Educational Apparatus, especially the graduated cylinders, are of value as they teach relative size.

Another early exercise for impressing number concepts, requiring but a modicum of muscular co-ordination is *Bead Stringing.*

First use shoestrings and the large wooden "beads" in the form of balls, cubes, cylinders, etc., as purchasable in any toy or kindergarten store. Later, beads of smaller size, different material, and varied colors can be introduced. Of course, the very first exercises will not emphasize number or counting; they will merely teach the trick of the stringing. But as soon as that is mastered, there will be first of all a counting of the beads irrespective of their form size, or color. Then, we may have the child string small and large beads, or cubes, balls, cylinders, etc., in alternate numbers of two, three, or what not. Different colors will be introduced in the same way, until quite elaborate patterns are made by the children.

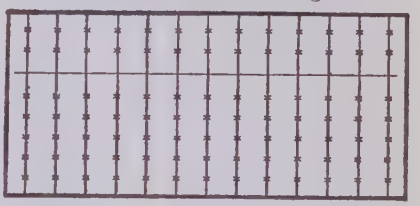


Let us not forget, however, that the child will at first not always be sure of the exact number he uses, or of the number name fitting the number itself. We must be patient. The child will often string his beads correctly without being perfectly conscious of the number he uses; his will be a space concept, or a geometrical concept, rather than a numerical concept. But he will subconsciously store up the experience, and will soon surprise us by a correct understanding of the numerical value.

Let us further understand that this counting process, although it would seem mere addition, introduces from the start the other operations. The one will appear as two less one; the three, as four less one, etc. Again, the grouping of twos or any other sequence of equal numbers will suggest multiplication as well as division. The groups may be distinguished by using different forms, or sizes, or colors.

The beads strung on taut wire and fastened to a frame, as in the *NUMBER Frame* or *Abacus*, would seem to be simpler to handle than when loose, and to be strung by the child. But first of all the abacus requires balancing by the child with his left hand to give him the chance of moving the beads with his right; this is not so easy to many young children as stringing large beads on a shoestring. The fastening of an abascus arrangement to children's desks will, of course, obviate this objection. But the use of the abacus is more formal than the stringing of beads which offers more variety and a play interest; besides, it has an ormental character as the child can construct necklaces, bracelets, and all kinds of festoon arrangements. A further development of the beadstringing exercise is found in the use of leaves, acorns, nuts, flowers, etc., in place of the beads, thus leading to nature study as well as to aesthetic training, while the numerical element remains.

But the abacus affords new possibilities. The beads are arranged in rows of ten, each row showing a different color. There are usually ten beads in a row; and five, or ten, rows. Some larger forms show an arrangement by twelves. This is not so good for primary beginnings, but can be used to teach the multiplication table up to twelve.



Mere counting will initiate this exercise, as in all other exercises. The child will learn that the beads are arranged in rows of ten, and that there are fifty, or whatever the total may be, all together. Now the child again may arrange the beads in groups of twos, threes, and so forth. He will move over 1 red bead, 2 orange beads, 3 yellow beads, 4 green beads, 5 blue beads, etc. He will construct different numbers by combining several rows; f. i.: 13—10 in one row plus 3 in another. He will discover that the ten in one row can be arranged in five groups of two each, learning the division of ten, and the multiplication of two, and by dividing the ten into two groups of five each, the multiplication of five by two. There is an endless variety of these exercises, and we may well be reminded at each step that all four fundamental operations can be taught together.

Abacus showing multiplication of 3 by 5, as well as of 7 by 5; and addition of 7 plus 3.

The *Chinese number frame* is a shallow box, arranged in two lengthwise compartments, one only one-half as wide as the other. Thirteen thin reeds or rods, on which beads are strung, are so placed across the box that in the wider section of the box, there are five beads on each; on the narrower, only two. Beginning at the left end, the five beads in the lower, wider section represent five units, from one to five. After counting the five you move one of the two beads in the narrower section up; this represents the total of five. Counting the beads in the wider section over again, you have another five; then you move the second bead in the narrower section and now have two beads there, each representing five, or a total of ten. The tens are in the second reed next to this to the right; each bead of the five in the lower section represents ten, or a value equal to the sum of the two beads on the first reed. In this wise you go on. It sounds very complicated, but is not when you once manipulate one of these frames which are today used in every Chinese laundry in this country to compute the amount of your bill. The introduction of this Chinese counting board will give you and your children a very great selection of number constructions, in all the four operations, up to very large numbers indeed.

The apparatus looks something like this:

Sticklaying is another very valuable device in teaching the fundamentals of number. Sticks, natural wood and dyed, can be bought in toy and kindergarten stores, by the box, and in different lengths. They offer opportunities not only for sticklaying but for comparing lengths. For the mere laying of sticks, to teach counting and computation in the four fundamental operations, toothpicks can be used, which may be dyed with Easter egg dyes. But the objection to them is that they are too small for the tiny fingers to handle; the bought sticks are more substantial. The Montessori Apparatus offers graduated rods from 1 meter length down to 1 decimeter; these are very helpful on account of their size, but rather expensive.

Sticks may be laid in rows, first, one in the first, two in the second, etc., like this:

I
II
III
IIII
IIIII, etc.

In rows of twos, threes, etc.

II II II II
III III III III

It will be observed that such an arrangement combines the space relation with the numerical relation, which is very helpful

Then in rows of equal numbers:

IIII
IIII
IIII
IIII, etc.

All the combinations of each number, as this, of 5;

I I I I I
II II I
III II
IIII I
IIIII

The multiplication tables can be easily demonstrated in this fashion. Here is the table of two:

II
II II
II II II
II II II II
II II II II II, etc.

Again, here is division:

IIII=II II.

This can be extended as far as the child can follow. In place of the sticks, beans, seeds, beads, almost any other object can be used. Introducing the colors, variations may be effected.

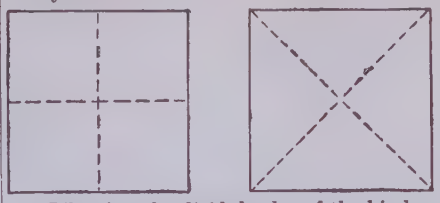
With sticks of different lengths, the first exercise would be assorting them, the one-inch sticks in one pile or box; the two-inch sticks, in another, and so on. Then they may be laid out and arranged according to their relative lengths; first, merely in the form of ascending steps, then by matching lengths. There may be combinations of matching a five-inch stick with one two-

inch stick, and one three-inch stick; or one four-inch stick and a one-inch stick. Or you will have the child discover that two two-inch sticks match the length of a four-inch stick, and so forth.

This may be, in many cases, a convenient time to introduce the *backward* counting, as now the children will have achieved considerable facility. Have them count backward by ones, first from three to one, then from four to one, and so on. Then, by twos, by threes, etc. All this gives drill in the process of subtraction and even in the foundations of division. Let us remember that multiplication is merely the repeated addition of the same number; and we may consider division, in one sense, as a continued subtraction of the same number, from the principal.

Further opportunity for number exercise is given in *ringlaying*, *tablellaying*, the *weaving of mats*, and similar kindergarten occupations which afford the child a great deal of pleasure. These occupations introduce a larger element of beauty and form arrangement; designs, borders and the like can be utilized in the development of an understanding of number relations, of harmony, of balance, of symmetry. In place of the tablets of wood in different natural colors, the child may use gummed paper pasters, in many colors and different geometrical forms: circles, squares, oblongs, stars, and what not.

Forms for Ringlaying.



A very acceptable pastime for even young children is *printing*. The Prang Company has produced a very helpful set of print sticks with which a great variety of exercises can be suggested. These sticks reproduce the geometrical forms already learned by the child, and allow of the making of all kinds of designs. Above are squares and circles of different sizes: triangles, oblongs, and even wavy lines.

These forms make it possible to teach the division of figures with ease; halves, thirds, fourths, etc., can be easily demonstrated. Of course, the child should be encouraged also to divide real things, like apples, the kernel of walnuts, and other things; and parents should not be too much disappointed if the division is not very accurate. Accuracy is acquired slowly.

Some firms offer cardboard disks to teach the division of the circle; different colors are employed to distinguish the halves, thirds, quarters, etc., which have to be matched with the circle itself.

One caution is needed: the children must learn to understand that division means dividing the whole into *equal parts*. As soon as actual wholes are divided, like a circle, or a square, or an apple, this must be emphasized. Unequal parts must be shown and used for the demonstration that they are not equal, although they may represent a division of the whole.

Paper Folding is another help in teaching divisions. Use square or round pieces of paper; fold diagonals, or at right angles. Divide the folds again and again. The folded parts may be cut out and matched. By using colored paper, a multiplicity of designs may be produced, pasting the pieces upon tinted backgrounds in various ways.

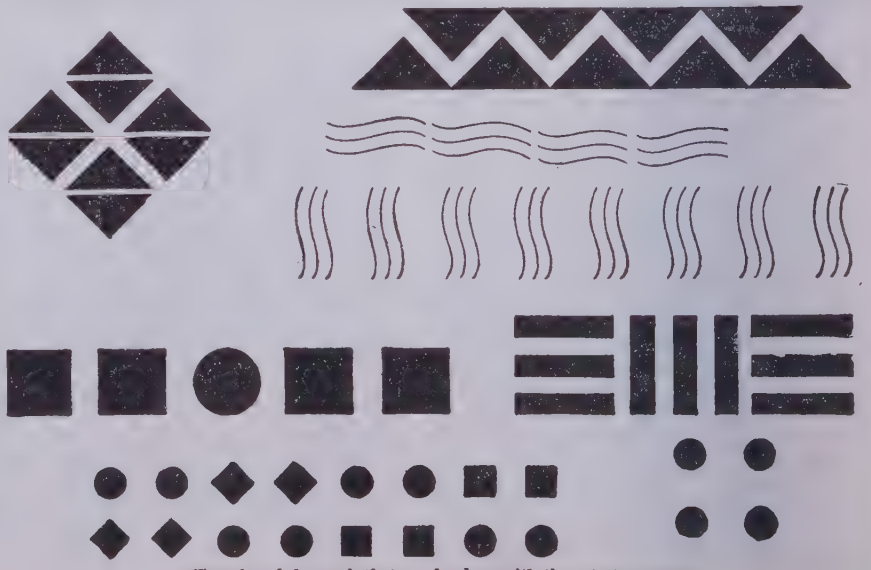
Likewise, the *divided cubes* of the kindergarten gifts will assist in teaching divisional parts, as well as form, in the matter of geometrical solids.

In order to develop the idea of relative quantity, *measuring* is a very important exercise. In fact, it should accompany all other work. The child should be encouraged to measure lengths, bulk, liquids, etc., all the time. Not that the idea of inches and feet, of pints and quarts, or other standards, should be at once introduced. No. Just as the child will first acquaint himself with the *general differences* in the length of sticks, cords, etc., and will only in time recognize standards of measurement and denote these differences with something like precision, so we want to first give him the notion of larger and smaller, of more and less.

He may use strings and rulers to measure the length and width of table tops, windows, the length of walls, etc., etc. He may then learn to determine the exact length in inches and feet, or yard. Begin with the larger measure, and work down to the smaller. It makes little difference whether the child at once remembers the term "yard", "foot", or not, as long as he recognizes variations in length. Let him cut strings which represent the length, of, say, a window sill; or apply his knowledge in making a cover for his bureau. Let him make knots in his strings to denote different measures he has discovered. Counting knots in strings was one of the primitive methods of computation. The child should have small and large bottles, dry measures (first merely cups and pots), and constantly learn to compare. Gradually he will employ the standard measures and commit the "tables" to memory.

On his walks, let him measure the number of steps he takes; the relation of the length of his step to the foot, or the yard, the rod, the mile. He will soon learn to estimate distances much more accurately than you may expect. Let him measure or estimate the height of bushes, of trees, of poles; the width of a road or a brook. Nature offers such an abundance of material that it is unnecessary to say more. Always be satisfied at first with rough statements; accuracy will be achieved in time.

Of course, all these exercises imply the four operations.



* * *

So far, we have been dealing with concrete things only, in other words, with *denominate number*. That is to say, not entirely. The child, in his early efforts to count, and to use number names, is already abstracting his ideas from the concrete to the un-named, the indenominate, the mere number concept. In fact, as soon as he masters number names, he will do a great deal of computing, in adding, subtracting, multiplying, and dividing, abstractly. When the little boy whose learning process was described on p. 305 asked himself and others the questions: "Isn't two fours eight?" and so on, he was not thinking of four or eight marbles, but of abstract numbers.

With the introduction of the *symbols*, that is to say the *figures*, from 1 to 9 and 0, another element enters.

Perhaps, a child has at first difficulty in understanding the *Arabic figures* which are so familiar to us. A transition method would be to use the sticks as symbols, or rather the marking of sticks on paper, such as we often do in tallying at card games, or in scoring votes. Every group of five is denoted thus: 𝍸, or 𝍸. Thirteen would appear thus: 𝍸 𝍸 III. Some have suggested that it may be advantageous to use the *Roman numerals* before we use the Arabic numerals as they also operate with simple additions and subtractions. When once it is known that V means five, and X means ten, it is easy to construct III = 3, IV = 4, or five minus one; XI = 11, or ten plus one; XX = 20, or two tens, and so on. Of course, computation is less comfortable with the use of these symbols than with the Arabic notation.

Even before the use of numerals, however, the *multiplication table* may be learned by heart; one table after the other. There is no need of hurry, or of anxiety. True,

(Samples of the work that can be done with the printing sticks.)

the tables will mean nothing to the young child at this time, except as far as he can verify the tables by actual experience in his number work with objects. Many years ago, a clever English educator expressed himself in this manner: "A boy may say 7 times 5 equals 35, when he does not know much about 5 or 7, except that he has had 7 marbles or 5 balls; and he has no conception whatever of what 35 represents; he has only learned to make certain noises in a certain sequence." This is correct. But this is also the period in a child's life when he has a retentive memory of a more or less "mechanical" kind, as it is called. By committing the tables to his memory he stores up a set of tools which will come in useful later, for rapid calculation. Many early activities of a child have no purpose in themselves but are a preparation for future purposeful performances.

As soon as the child masters the numerals, the multiplication table can be practised with the use of a table like this:

1	2	3	4	5	6	7	8	9	10	11	12
2	4	6	8	10	12	14	16	18	20	22	24
3	6										
4	8										
5	10										
6	12				36						
7	14										
8	16										
9	18										
10	20										
11	22										
12	24										

The table is either drawn on a large manila board, or on the blackboard. It contains 144 squares, arranged in 12 rows of 12 squares each. In the upper horizontal row write the figures from 1 to 12; likewise in the first vertical row on the left side. The exercise may be played as a game, either by several children, or by parent and child. The idea is to multiply the figures of the top row with those of the left row, or vice versa, and to write the results in the corresponding squares.

The second row would then contain the figures, as indicated, 2 times 2=4, 2 times 3=6, 2 times 4=8, etc. In the sixth row, we would find, as also indicated, that 6 times 6=36. The product can always be found in the square where the two rows meet.

Further, compare the rows, f. i., the second with the fourth, and you will also find that 2 is $\frac{1}{2}$ of 4, 4 is $\frac{1}{2}$ of 8, 5 is $\frac{1}{2}$ of 10, etc., so that we have also a demonstration of quotients.

It may have been noticed that we have used the term "times" written out, and not the sign x. We have done this for a good purpose. It will make it far easier for the children if they learn to use the arithmetical signs in the proper manner from the start; there is as a rule too much confusion in their reading. The sign "x" does *not* mean "times", but "multiplied by." *The number to be operated upon always stands first.* When we say, 3+4=7, we mean that 4 has been added to *3*; 3—1=2, means that one has been taken away from the *3*; in the same way 3x4=12 indicates that the *3* has been taken 4 times, or has been "multiplied by" 4, and not that the four has been taken three times. Likewise, when we say 12÷4=3, we mean to say that the *12* has been divided by 4.

In introducing division in the form of examples, we must also remember that division really implies *two different processes.* The one is to find the number of times a smaller number is contained in a larger one, with or without a remainder; the second, to divide a number into so and so many equal parts. Thus: 12÷4 may mean that we wish to discover that the 4 is contained three times in 12; or again, that when we divide 12 into four equal parts, each part contains three. If we, f. i., ask how many times are four inches contained in one foot or 12 inches, we shall find that we have three times four inches. But if we ask what is one fourth part of one foot, we shall put it down as containing three inches. To write the two examples correctly would therefore make them look like this:

12 in.÷4=3 in., and
12 in.÷4 in.=3.

These are two different things, and unless they are clear in the child's mind from the start, he will have difficulties in analyzing his examples later.

Another difficulty which ordinary methods introduce is the distinction between "long" and "short" division. There is no difference at all between the two processes. "Short" division examples are short because smaller numbers are used, and there is usually no remainder; "long" division examples are long because larger numbers are used. It is best not to make this distinction, and also to adhere from the first to the form of an equation, like this:

12÷4=3, or 4)12=3.

It is evident that these two forms exemplify the two types of division explained; the first really means, 12 divided by 4 gives 3; the second, 4 is contained in 12, 3 times. The second form may be chosen in preference to the first for all examples because it introduces the longer division examples with greater ease.

To lead over to the so-called long division we may have the child write the tables this way:

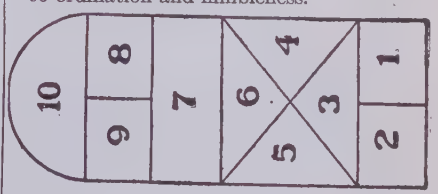
3=1 three
4=1 three plus 1
5=1 three plus 2
6=2 threes
7=2 threes plus 1
20=6 threes plus 2
21=7 threes
22=7 threes plus 1
23=7 threes plus 2
24=8 threes, etc.
6 x 1 plus 3=9
6 x 2 plus 3=15
6 x 3 plus 3=21, etc.

This will be an easy process after the children have performed all the try-out exercises described before, with objects of all kinds, and if they are encouraged to "prove" their computations by constant recourse to actual values. At this stage there will be ample opportunity for such proving in connection with the *manual training* exercises a child will indulge in now, in measuring and computing lengths, widths, etc.

To lead over to the more complex problems in division it will be helpful to suggest to the child to write out even his simplest forms completely, without omission of the intervening steps. Thus:

3)12 = 4.	3)128 = 40 plus 2 plus	
12	120	$\frac{2}{3}$ = 42$\frac{2}{3}$
00	8	
	6	
	2	

The complete statement would refer to the fact that we first want to find, in the second example, one third of 12 tens, which is 4 tens, or 40; then one third of 8 units which is 2 with 2 left over which adds $\frac{2}{3}$ to the entire quotient so as to make it 4 tens, 2 units and $\frac{2}{3}$ of a unit, or 42$\frac{2}{3}$.



The same process can be followed out with the longer examples. Perhaps at first this will require time and patience, and may seem to some unnecessary. But it is these initial steps which must be fully mastered. Afterwards short cuts may be introduced, for the child will always understand the underlying principle.

Number Games and Songs.—There are numerous games and songs which will help in impressing the concepts of quantity, order, and number relation. The song of the "Five Little Chickadees" is well known to kindergarteners, and can be played as a game.

There is the old game of "Hop-Scotch" which all children like to play. The figure as here given in the diagram should be described on the ground, about twelve feet in length. From a line, or spot, a short distance from No. 1, a stone is tossed into No. 1. William Wells Newell, in his book, *Games and Songs of American Children* (Harper Bros.), describes the game as follows:

The boy or girl hops on one foot into No. 1 and kicks out the stone which is then thrown into No. 2. The player now hops into No. 1, and jumps into No. 2, in such a way that one foot is in the division 2, and one foot in 1. The stone is kicked into 1, and then out, and so on. In passing through divisions 1 and 2, 4 and 5, 8 and 9, a straddle must be made, one foot being placed in each; in the others a hop only must be taken. A failure to throw the stone into the right place, or to kick into the right division, or leaving it on any line, or touching the raised foot, or stepping on a line, puts out, and the next takes his or her turn. In other localities, no straddling step is taken, but the player, in certain divisions, is allowed to place the stone on his foot, and so expel it from the figure at a single kick; the compartments also vary in number and arrangement.

This game does not only impress the first ten numbers upon the child's mind but implies a splendid exercise in muscle-co-ordination and nimbleness.

"Odd and Even" is a guessing game. It is played by two players one of which may be the parent, with a small number of beans or other counters held in the hand of each. Then one asks the other, "Odd or Even?" If the guess be even, and the true number be odd, it is said, "Give me one to make it odd," and vice versa. The game is continued until all the counters belong to one or the other of the two players.

A similar game is "How Many Fingers?" A child hides his head in another's lap and guesses the number of fingers raised. Sometimes this rhyme accompanies the question:

Mingledy, mingledy, clap, clap, clap,
How many fingers do I hold up?
"Three."
Three you said and two it was, etc.

This game, known as "Morra", has been played from the time of the ancient Egyp-

tians; in the more complex forms the sum of the fingers raised and guessed right by each of the two players is counted up and scored.

Many other games can be invented by the children themselves and developed by the parent.

Ball games are naturally in this group. Matching one another in the number of catches; measuring and comparing the distances from which the ball is thrown and caught, and numerous other variations of the same counting and tallying game will arouse and hold the interest of children for a long time.

Dominoes afford much sport and training. You can use them in the ordinary games, matching the numbers, and counting up the losses; or you can vary the game by requiring the players to complete a certain number, as 10, or 12, by placing the needed numbers together: 4 and 6, 5 and 5, to make 10; or 6 and 6, 5 and 6 and 1, etc., to make 12, etc. The doublets, like 2 twos, 2 threes, etc., also introduce some opportunities for multiplication and division, and with the use of more than one domino block at the same time, the number games can be varied and extended.

Some manufacturers of toys and of school material have produced new varieties of domino games by offering cards with the domino arrangement of dots, using higher numbers, up to 10 and more, instead of merely those from 1 to 6, as in the domino game proper. With the use of them, all the four operations can be successfully played.

Other cards add to the number forms composed of dots, the corresponding figures, or number symbols, on the reverse side, for study and comparison. Still others introduce pictures of flowers and animals, for *quick perception and computation.*

To develop quick perception and computation, the cards are held up to the child's inspection for only a very short time, and he is expected to perceive quickly what number is represented, or what sum is required by adding up the two divisions of the card. Naturally, it is well to begin with a longer exposure, of, say, five or six seconds, gradually diminishing the time of exposure until only a moment is allowed, so that the child's perception is quickened. Caution is in order against the child falling into the habit of merely guessing.

This very valuable exercise in rapid and accurate number perception and computation can also be played with *dice*, first with one, then with two, where addition comes in, and even more. By removing one or or two dice after the first simultaneous exposure the exercise may introduce subtraction.

Another helpful adjunct to number training is afforded by our ordinary *playing cards.* Here, in addition to the number, or pip, cards proper, we have the court, or figure, cards, to which, as to the ace, different values may be given, as 11 to the knave, 12 to the queen, and 13 to the king, and, in some cases, 14 to the ace.

The first exercise for a young child is merely to assemble the shuffled cards in suits; then to arrange each suit in the order of counts. He may then play by putting the four aces together, adding them up as ones; in the same way, the twos, threes, and so forth. It is evident, that games of subtraction, multiplication and division are offered by the use of cards from the very start.

But then we have our regular games, such as introduce scoring and tallying, and will train the child's power of memory retention. One of the simplest games of this kind is Fan Tan; then we have Casino, Hearts, Sixty-Six, all of which can be played in various ways. Some of the more popular family games like Old Maid, have their value. They will afford endless amusement no less than training to the children.

One of the supplementary advantages of using cards and similar games with children as tests of their skill in mastering number relations and in thinking out possibilities, is that children will enjoy the sport without attaching the gambling idea. For it must be strictly avoided to have them play for prizes of any kind, and if it were even only a collection of pins or marbles. The fun to them must be in playing the game as such.

Even young children may be taught some of the simpler *Solitaire* games. "Canfield" is one of them. It can also be played by two players, and is then known by some as "Idiots' Delight". A helpful solitaire game for children is "Basset". It is played as follows:

Lay out four cards: ace, two, three, four. On these build as follows: On the ace will go the two, three, four, five, etc. On the two will go the four, six, eight, ten, etc. On the three will go the six, nine, etc. On the four, the eight, twelve. The court cards are used as numbers, 11, 12, and 13 (knave, queen, king). When the cards are played successfully, all will be distributed on the four piles, with the kings on top.

"Tit-Tat-To" is a solitaire game which introduces a new feature which will be used again in another set of number games. It is played with nine cards in sequence from ace to nine. They are to be placed in three rows of three cards each. Then, by changing their position they must be so disposed that the number of pips in each row, counting the cards horizontally, perpendicularly, and diagonally, will make the sum of fifteen each time.

As soon as the child masters the *figure symbols*, there is a variety of games and pastimes. We have the old game of *Lotto* which can be introduced quite early and will assist in the fixing of number symbols. Again, we have the *Fishpond, Parcheesi*, and a multitude of other games as offered by the toy stores.

Now, the Tit-Tat-To principle can be employed in the development of the *Magic Squares* and *Magic Triangles.* To work them out, the child should use counters, with the figures written or printed on; the number counters of a Lotto game will do very well. To illustrate:

A
B C
D E F

The figures from 1 to 6 should be so arranged that A plus B plus D = 9; A plus C plus F = 9; and likewise the third side, D plus E plus F = 9. This is one solution:

2
6 4
1 5 3

The same counters can be so arranged that the sum each time is 10, or 11, or 12. Again, a larger number of counters can be introduced, with larger sums. In the same way, "magic" squares are used; here is one example:

A B C
D E F
G H I

This is a so-called solid square, with a counter in the center; hollow squares omit this center counter. In the sample given, the numbers from 1 to 9 can be so arranged that they give 15 whichever way you add three numbers, vertically down any of the three columns, or horizontally, or diagonally. This is a solution:

4 9 2
3 5 7
8 1 6

These arrangements are a source of never-ending delight with children and develop in them facility of number combination which will stand them in good stead in many "practical" examples.

An example of a subtraction puzzle with counter is this:

Arrange nine counters as follows:

1 5 9
3 4 8
2 6 7

Now tell the child to move ONE counter from its present position to another pile, in order to make the sum of the counters in all the three piles the same. Of course, this is accomplished by moving the 9 from the third pile to the first.

The more of the *puzzle interest* of the child we can employ in teaching him number the more sustained will be his application, the more eager will he be to find the right solution. In fact, all problems or examples can arouse this puzzle interest when rightly presented. Every solution means a mastery over an obstacle, the conquest of a difficulty, the solution of a riddle.

Some of the special devices that may be used in this connection are the "Prestocard Multiplication Table" (Glen Ridge, N. J.), and the "Quiz Educational Toy" (Zestoy Mfg. Co., New York).

The following *drill charts* used by the author in many ways will assist greatly in fixing the decimal system of number relations in the mind of the child. Charts I and II are dealing with tens; the third chart, with hundreds, up to 10,000.

The arrangement of the charts is such that the relationship of numbers within the tens is readily grasped. The child should read each row separately at first, like this:
1 2 3 4 5 6 7 8 9 10;
then, the second row, the third, and so on. The next step would be to read the tens from the top line down to the bottom line:
10 20 30 40 50 60 70 80 90 100.

It will be well to call these first "tens", naming them "one ten", "two tens", etc., to "ten tens", so as to impress the decimal relationship; substituting the terms "twenty", "thirty", etc., only after this relationship is fully grasped.

The child will soon become interested in discovering further relations of tens, counting downward in the first compartment: 1, 11, 21, 31, etc. Also: 2, 12, 22, 32, etc., and so through the compartments. Further, he will discover that, going diagonally from the upper left corner to the lower right corner, he adds up by elevens (11 being the number given under 1): 1, 12, 23, 34, etc. Choosing the second number given below 1, viz. 21, he will find the corresponding sums by first taking the next number to the right of 21, viz. 22, and then following the same rule: going down two and one to the right, in the further operation: after 22, 43, then 64, 85; here we stop as this Chart I does not go beyond 100. But tacking on the corresponding columns of Chart II, we find 106, 127, 148, 169 and 190.

Parents and children will vie with each other in discovering more and more of

these games of addition. Chart III allows of the same illustration with hundreds, emphasizing the fundamental principles of the decimal system still further.

The Groszmann Drill Chart of Tens, I.

1	2	3	4	5	6	7	8	9	10
11	12	13	14	15	16	17	18	19	20

171	172	173	174	175	176	177	178	179	180
181	182	183	184	185	186	187	188	189	190
191	192	193	194	195	196	197	198	199	200

The Groszmann Drill Chart of Hundreds

100	200	300	400	500	600	700	800	900	1000
1100	1200	1300	1400	1500	1600	1700	1800	1900	2000
2100	2200	2300	2400	2500	2600	2700	2800	2900	3000
3100	3200	3300	3400	3500	3600	3700	3800	3900	4000
4100	4200	4300	4400	4500	4600	4700	4800	4900	5000
5100	5200	5300	5400	5500	5600	5700	5800	5900	6000
6100	6200	6300	6400	6500	6600	6700	6800	6900	7000
7100	7200	7300	7400	7500	7600	7700	7800	7900	8000
8100	8200	8300	8400	8500	8600	8700	8800	8900	9000
9100	9200	9300	9400	9500	9600	9700	9800	9900	10000

Subtraction in this case is merely the reverse process, "counting backwards".

After exercising with the charts in full view of the child, the charts should be withdrawn, so that the child may test his ability to retain a mental picture of them. Rather than allow erroneous impressions to creep in, it will be well to show the charts again and again, until their image is firmly fixed upon the child's mind. Remember: this is not a *test*, but an *exercise*. It is of the utmost importance that the child should form and retain clear and correct mental images of these number relations.

The arrangement of the charts also allows their use in multiplication and division drills. For instance: 2x2 = 4; 2x3 = 6, etc. Also, 2x11 = 22; 2x21 = 42, etc. It will be seen that there is a geometrical relation of the figures representing these values. Children will delight in drawing pencil lines to mark these steps. For such exercises it is suggested that the charts be manifolded (hectographed or mimeographed) for individual use.

The difference between *prime numbers* and *composite numbers* can be studied at home by way of a game, using the so-called "sieve" of the famous Greek mathematician Eratosthenes, who lived several hundred years before Christ. Divisors and multiples can be discovered by using the same device. This is the sieve:

~~1~~	11	~~21~~	31	41	~~51~~	61	71	~~81~~	~~91~~
2	~~12~~	~~22~~	~~32~~	~~42~~	~~52~~	~~62~~	~~72~~	~~82~~	~~92~~
3	13	23	~~33~~	43	53	~~63~~	73	83	~~93~~
~~4~~	~~14~~	~~24~~	~~34~~	~~44~~	~~54~~	~~64~~	~~74~~	~~84~~	~~94~~
5	~~15~~	~~25~~	~~35~~	~~45~~	~~55~~	~~65~~	~~75~~	~~85~~	~~95~~
~~6~~	~~16~~	~~26~~	~~36~~	~~46~~	~~56~~	~~66~~	~~76~~	~~86~~	~~96~~
7	17	~~27~~	37	47	~~57~~	67	~~77~~	~~87~~	97
~~8~~	~~18~~	~~28~~	~~38~~	~~48~~	~~58~~	~~68~~	~~78~~	~~88~~	~~98~~
~~9~~	19	29	~~39~~	~~49~~	59	~~69~~	79	89	~~99~~
~~10~~	~~20~~	~~30~~	~~40~~	~~50~~	~~60~~	~~70~~	~~80~~	~~90~~	~~100~~

"This sieve," says Dr. Winifred Sackville Stoner who had used it in the training of her own daughter, "seems to amuse all children who like to mark out the composite numbers with red ink, and it impresses on their mind all prime numbers so that they recognize a Mr. Prime whenever they see him." It will be noticed that this "sieve" is similar to the Ten-Table of the author which can be used in various ways.

Mrs. Stoner, in her book, *Natural Education* (Bobbs Merrill), also describes the manner in which she taught her daughter *cancellation* as a short route and interesting game. With her permission we quote:

"In a box we place all sorts of numbers not exceeding two figures. These are to be our soldiers. Then we choose a name for ourselves, Wellington being a favorite with Winifred and Napoleon with me. We draw a line of battle and we are ready to begin. Winifred draws a number from the box. Suppose it is ten and that she has chosen the upper position above the line for her men. Then she puts 10 (in writing) above the line. I draw and get only two men, but I place them below the line ready for battle and feeling hopeful that my next draw will make my army larger than Winifred's. She draws and gets only two men, whom she places ready for action while I make my second draw and win five. Again Winifred draws and gains four. Now her line of battle is ten times two times four. I draw another two and my men stand two times five times two. At a glance you see that she has beaten me in number but we fight the battle to see how many of her men I can kill. My first battalion of two advances against her ten and is wiped out of existence though reducing the ten to five. Then she uses this five to kill my five but they die in battle. My two march against her two and both fall, but she has still four men remaining and so Wellington has won another Waterloo. This is how the battlefield is arranged:

~~5~~
~~10~~x~~2~~x4 Wellington's men
=4

~~2~~x~~5~~x~~2~~ Napoleon's men
=1

This is really a very interesting game for all children to play.

The only difficulty may be that the children will argue that Napoleon had not one, but no man left. That "cancellation" reduces the cancelled numbers to the value of one is one of those mathematical axioms which it is almost impossible to explain to children. Of course, 4 divided by 1 is still 4, and the children will have to be satisfied with this, just as we older ones will have to take Einstein's theory of relativity on faith. If the position of the forces had been reversed, so that $\frac{1}{4}$ had been the result, the explanation would perhaps be easier.

Fractions. When once the idea of fractions is understood, their manipulation is relatively easy. In common fractions, the only puzzling thing seems to be their multiplication and division. But it can be made plain in something like this manner:

Suppose the problem is to find $\frac{1}{2}$ of $\frac{3}{4}$. Let the child understand $\frac{3}{4}$ means 3 *fourths*, that is to say three definite things. "*Fourths*" is really a denomination. As we would say, $\frac{1}{2}$ of 3 apples is one and one-half apples, as $\frac{1}{2}$ of three is one and one-half, so we have here $\frac{1}{2}$ of 3 fourths = one and one-half fourths. Now we know that one-half of one-fourth is one-eighth; so we have as an answer, one-fourth and one-eighth. To express this in one quantity we remember that one-fourth = two-eighths; thus, by adding, we have $\frac{2}{8}$ plus $\frac{1}{8}$, or $\frac{3}{8}$. Consequently $\frac{1}{2}$ of $\frac{3}{4}$ is $\frac{3}{8}$. Let the child fully understand each step. He will then joyfully appreciate the discovery that there is a short cut to the finding of the answer, namely, that we merely multiply. Thus:

$$\frac{1}{2} \text{ of } \frac{3}{4} = \frac{1 \times 3}{2 \times 4} = \frac{3}{8}$$

This is *multiplication of fractions*; the problem can also be written in this manner: $\frac{1}{2} \times \frac{3}{4} = \frac{3}{8}$, or better: $\frac{3}{4} \times \frac{1}{2} = \frac{3}{8}$, just as we would write $\frac{1}{2}$ of $\frac{1}{2}$ apple = $\frac{1}{4}$ apple, or $\frac{1}{2}$ apple x $\frac{1}{2}$ = $\frac{1}{4}$ apple.

In *division of fractions*, we may argue in this form:

$\frac{6}{6} \div \frac{1}{6}$ means: how many times is $\frac{1}{6}$ contained in $\frac{6}{6}$; obviously 6 times.

This is the same as, with inverted divisor:

$$\frac{6 \times 6}{6 \times 1} = \frac{36}{6} = 6.$$

How many times is $\frac{2}{3}$ contained in $\frac{3}{4}$?

The same as: $\frac{3}{4} \div \frac{2}{3}$. $\frac{3}{4} = \frac{9}{12}$; $\frac{2}{3} = \frac{8}{12}$. $\frac{8}{12}$ is contained in $\frac{9}{12}$ one and one-eighth times, or $1\frac{1}{8}$.

Short cut process:

$$\frac{3 \times 3}{4 \times 2} = \frac{9}{8} = 1\frac{1}{8},$$

by inverting the numerator and denominator of the divisor and multiplying.

Decimal Fractions. These can be most easily introduced through a previous manipulation of U. S. money. The division of the dollar into 100 cents forms the basis. There is not a child that will not at an early age become interested in money. The toy stores sell toy money in boxes, representing on card disks of corresponding sizes and with the denominations printed thereon, the various divisions of the dollar. For later exercises in buying and selling, in connection with store-keeping, such as has been elaborated by the "Model Store" movement (Educational Foundations, Brooklyn), it can be used to advantage. But young children are not interested in it; they want the real coins, and want to buy real things. They soon learn to manipulate pennies, nickels and dimes. Then they will understand the quarter, and that four quarters make one dollar. Out of practical experience in making change they will learn to master the rudiments of the decimal fraction idea, and will be more ready to transfer their knowl-

edge to decimal fractions in the abstract, or in application to other values. The same is true of *percentage*. Just as 25 cents are $^{25}/_{100}$ of a dollar, or a fourth (a quarter) of a dollar, the sum represents 25 per cent of the same amount. 10 cents is ten per cent, or 10%. And so on. The child will easily learn to add, subtract, multiply and divide decimal fractions. Indeed, he will find it much easier to manipulate them than the so-called common fractions, and will hope for the time when all our measures of length, distance, liquids and dry stuffs will be of the centigrade order.

The teaching of *time* is a slower process than one would imagine. But when the child has learned the divisions of circular objects, there will be an early opportunity to teach him at least the hours, and their main divisions. The recognition of minutes comes much later.

Area and *bulk* are best introduced through the kindergarten blocks and tablets. By arranging squares, especially if they have a definite size corresponding to the measuring standards in use (inches, feet), the first problems in area can be understood by the child. He will learn without difficulty that a one-inch square covers one square inch of surface; but if there is an area twice the length and twice the width, he needs four squares, in other words, that with a two-inch width and a two-inch length, he needs four one-inch squares to cover four square inches. And so on. He will also learn to appreciate *scale*, substituting feet of a real room for the inches of his drawing on the paper, and learning gradually the significance of map-drawing to a scale.

ARITHMETIC.—First Steps in Number Training.—Arithmetic in the first three grades is called "number work". It expresses in the simplest way the numbering sense or the counting instinct by which the child first gets hold of quantitive values in his environment. First year number work to the child is largely incidental, though the teacher must have definite aims and purposes. The simplest way to get number ideas is to count small groups of similar objects and find "how many" in a group. The mere rhythm of counting is pleasing to children, counting by 1's to 100; by 10's and 5's to 100; by 2's to 12 or 20; by 3's to 12 or 15; count backward by 1's and 10's. Children will have practical use for this knowledge in connection with games, songs, stories, manual work, and in the daily business of the schoolroom and the home. Through rhymes and jingles as in this *Ten Little Indians* song they have the concrete lesson, the physical exercise and the merry game all in a delightful combination.

One little, two little, three little Indians.
Four little, five little, six little Indians.
Seven little, eight little, nine little Indians.
Ten little Indian boys.

Ten little, nine little, eight little Indians.
Seven little, six little, five little Indians.
Four little, three little, two little Indians.
One little Indian boy.

Games in great varieties may be arranged that will bring into exercise this number sense and the delight of dramatization.

Reading and writing numbers may be taught the first year to one hundred and the second year to one thousand. Make practical use of numbers taught, as finding pages of books, numbers of houses, etc. The teacher must always study her class and suit her pace to theirs.

Teach various forms expressing number relations, as: Three and three are six. Six divided into twos are three twos. Three twos are six. Six less three are Three. Two threes are six. One-third of six is two. Six divided into threes are two threes. Two-thirds of six are four.

With the operation teach also the appropriate sign as +, —, =, ×, ÷.

Appropriate combinations for drill should be presented after the child has formed a concrete image of the number relation. He should see one-half and be able to think one-half before he is asked to repeat the statement that one-half of six is three.

Developing the Idea of Fractions.—Children easily grasp the idea of fractional parts, but the teacher should keep in mind the completeness of the fractional idea, as Professor David Eugene Smith in his monograph on the teaching of arithmetic has pointed out in the following illustration: "We should remember that a fraction, say ½, is commonly used in three distinct ways, and that it is our duty to see that little by little all these become familiar to the child. These ways are as follows: 1. ½ of a single object, the most natural idea of all, the breaking of an object into 2 equal parts. 2. ½ as large, as where a six-inch stick is ½ as long as a foot rule, not half of it, but half as long as it is. This is essentially the ratio notion, and it is necessary to the child's stock of knowledge, but it is not necessary to make it hard by talking about ratios at this time. 3. ½ of a group of objects, as in case of ½ of 10 children."

New Facts and Processes.—Whenever new facts and processes have to be learned they should be learned in comparison with known facts. The child should handle and measure and be the aid of drawing get graphic representation of mathematical relationships. Use different magnitudes. Do not neglect to follow up with abstract drill work. Drill, fix, learn. Abstract drill work may be made as interesting as concrete, for all the joy of the game element in education may be made to enter into it.

Seat Occupation for Number Work in Primary Grades.—Devices for making number work practical have been worked out in great abundance. Every resourceful teacher has devices of her own. A few have been gathered here as suggestions.

Make pasteboard rulers 4 inches long, a foot long. Mark off into inches. Later mark off into fractions of an inch. Use these rules in measuring many things. Compare lines, surfaces and solids, with similar lines, surfaces and solids, as: This line is three times as long as that line. This line is one-fourth as long as that line. This rectangle is one half that rectangle. Find lines and surfaces in the room, and compare. Teach the child to see many things through the one. Unless that which he sees aids him in interpreting something else his observation is of no use to him. Cut, fold, paste paper furniture according to directions. Paint flags or cut badges of paper for holidays.

Rule lines, squares, oblongs to dictation and scale, sheets for weather record, record sheets, score cards for games. In all construction children should make the necessary computation to get total lengths and beaths and effect of any allowances, *e. g.*, laps in making boxes, for cover of a box compared with the box itself.

Have children measure each other, measure the growth of twigs, make comparisons in weights and measures. Arithmetic of a very practical kind is found in nature study, manual training, and in sewing and cooking. Boys and girls in industrial courses must measure and weigh with accuracy and skill.

Construction work when properly taught affords the finest mental discipline. Let children work out their own knowledge and make them personally responsible for their own results. Encourage them to tell what they know in free conversation. Such free work is far more valuable than formal recitation.

Test-Book.—A text-book is usually placed in the hands of pupils as early as the second half of the third year. From this time on the teacher follows the outlined course of study. Each year she must see to it the class thoroughly reviews the essential features of the preceding year's work and that such forward steps as are marked out for her grade be intelligently taken. Each year the work involves more difficult combinations and more complicated processes. The exact groundwork to be covered grade by grade differs in different schools according to the course of study outlined by different boards of education, but everywhere the essentials of class work are the same.

Class Work.—Cultivate the habit of first grasping the conditions of a problem, what is given, what is required, the relations between the two, the solution. Dictate original problems. Call for restatements of facts and conditions. Let pupil state process without solving. Dictate work slowly and distinctly without repeating. Demand close and lively attention. Call for original problems to illustrate principles. Secure familiarity with arithmetical facts and accuracy and ease of language. Typical problems, from Professor Smith's *Monograph*, to which this article is already under great obligations, have been borrowed here to show the nature of original work that may be done in different grades.

Two Groups of Problems Give to a Third-Year Class.—

Oral Exercise (without pencil and paper).

1. The coffee for our breakfast cost 6c, the potatoes 4c, the meat 32c, and the bread 4c. How much did the bread and meat cost? How much did the food cost?

2. The oatmeal for a breakfast cost 8c, the milk 4c, the fruit 10c, the rolls and butter 5c, and the eggs 8c. How much did this food cost?

3. For a dinner the meat cost 30c, the vegetables 20c, the dessert 20c, the coffee 15c, and the other food 15c. Find the total cost.

4. The meals for a small family cost $1.70 on one day and $2.20 on another day. How much did they cost for these two days?

Written Exercise.—The toad is one of man's best friends. One toad will keep a garden of 800 sq. ft. free from harmful insects.

1. At this rate, how many toads would protect from insects a garden 80 ft. wide and 100 ft. long?

2. The eggs of four toads were counted and found to be 7,547, 11,540, 7,927, and 9,536: How many were there in all?

3. If one out of 50 hatched, how many hatched? (Divide all by 50.) If 715 of these were destroyed by other animals, how many survived?

4. If each of these survivors destroys insects that would cause $10 worth of damage, how much are they all worth to a village?

Typical Problems for the Fourth or Fifth Grades.—1. Sarah's mother bought 4⅘ yds. of cloth for a coat, at $1.25 a yd. What did she pay for it?

2. She also bought 3½ yds. of lining at 50c a yd. and 4¼ yds. of braid at 20c a yd. How much did these cost?

3. She also bought 6 pearl buttons at $1.50 a dozen, and 2 spools of silk at 8c a spool. How much did these cost?

4. A dressmaker charged $5 for making the coat. What did the materials and making cost?

Typical Problems for the Sixth or Seventh Grades.—1. The following is, by weight, a good mixture of seed for a pasture: Kentucky blue grass 25%, white clover 12½%, perennial rye 28⅛%, red fescue ⅜%, redtop 25%. At 32 lbs. to the acre, how many pounds of each are used?

2. A farmer puts 5 acres into celery, setting out 20,000 to the acre. The yield being 1,500 doz. heads to the acre, what is the ratio of the plants matured to the others?

3. He pays $95 an acre for seed, fertilizer, labor, and other expenses, and sells the crop at 15c a dozen heads. What is his profit on the 5 acres?

An outline of the course in arithmetic in the eighth school year in Munich will show how the German schools are working out some practical ideas for girls who are soon to be the home makers. It is more complete than anything we have yet worked out in America.

The work for the year is as follows: 1. Simple domestic bookkeeping. 2. Calculation of the prices of foods, bought in large or in small quantities, together with the question of discounts. 3. Cost of meals for the home. 4. Daily, monthly, and yearly supplies for the kitchen.

Too much importance cannot be placed upon the nature of the original problems. They enliven class interest and give ample opportunity for correlation with other school subjects and with the livelier interests of the social environment. They should strain the powers of the child to think and compute, but they should not be too hard for him to master them independently. In every way problems should help the teacher to make school work practical.

Summary of Suggestions for the Teacher of Arithmetic.—1. There are a few things primarily essential in arithmetic that should be learned by every child. He should think in numbers as readily as he thinks in other subjects. He should be ready to execute his thought with quickness and precision.

2. Drill and repetition for accuracy and speed should be given day after day that the child may early master the mechanical difficulties of the subject, but drill should not become a lifeless mechanical repetition; it should be so varied as to produce thought and animation.

3. Such processes as addition, subtraction, multiplication, and division should be mastered early. Often much time is wasted in the upper grades learning facts and processes that should have been mastered in the lower grades when the child is passing through the stage in which this work can be done most easily.

4. The introduction of too many topics at a time should be avoided. The pupil should be required to meet but one difficulty at a time.

5. Begin with the concrete, then drill on number facts and processes. In the primary grades teach number facts for the most part in connection with the study of other subjects. Use material drawn from the number side of school experience and the simpler and more evident relation of home life. The continued use of any particular set of objects is tiresome and narrowing.

6. It is important to use objects freely whenever they assist in understanding number relations, but care should be taken not to fetter the mind with objects when it is ready for the abstract. Pass from observation to reasoning, from concrete to abstract, from facts to principles, from particular to general, and, very slowly, from the simple to the complex. The child passes through the stage of objects to that of representation of objects, to that of symbols. Noticeable progress begins when he can think of things not present to his senses.

7. In the intermediate grades emphasis should be laid upon the scientific aspects of the work, that is, rules and principles, in order to secure mastery of fundamental operations of numbers.

8. In the grammar grades considerable attention should be paid to the use of numbers in connection with the commercial and industrial activities of the community. Practical problems for all grades should be taken from industrial life.

9. In the working out of problems the child should be taught from the beginning to determine for himself the approximateness of results, appeal being made to the common sense check "Is this result reasonable?" "Does it agree with the conditions?"

10. Problems of graded difficulty should be given in all classes in order that even the weakest pupil may find enough that he can do to keep him trying. The exercise should bring in all the primary combinations of numbers and all the fundamental processes. The tendency to overuse a few combinations at the expense of others must be guarded against.

11. The teacher must exercise judgment as to the amount of written work. Oral expression should always precede written. In primary grades number work is largely given orally—good, clear, well worded expression. A little work well done is much better than a large amount of work over-hurried.

12. Insist upon neatness and a proper statement of steps taken.

13. Accuracy, facility, orderly arrangement, self-reliance, are cardinal virtues in number work.

14. In the assignment of work, assign some purely for drill and some purely to train the reasoning powers. If reasoning is difficult, mechanical processes should be simple.

15. Aim to obtain efficiency through the discipline of numbers. "The prime desideratum," it has been said, "is the ability to work accurately, with reasonable rapidity and with interest, and to know how to apply numbers to the ordinary affairs of life." There is moral value in the integrity of numbers that "cannot lie."

PRACTICAL HELPS IN ARITHMETIC

ADDITION AND SUBTRACTION

The following plan is suggested in teaching the combinations in addition and subtraction:—

1. Add **1** to every number up to **10**; later to **20**.
2. Subtract **1** from every number up to **10**; later to **20**.
3. Add

2	3	4	5	6	7	8	9	10
+2	+3	+4	+5	+6	+7	+8	+9	+10

Here the addends are equal and easily added. The figures should be placed as above and not 2+2, 3+3, etc., because the vertical form is the natural one which the child will use all through life. It does not look so formal and represents better what he really does with the objects.

4. Add

1	2	3	4	5	6	7	8	9
+2	+3	+4	+5	+6	+7	+8	+9	+10

Here one addend exceeds the other by **1**.

5. Subtract

2	3	4	5	6	7	8	9	10
−1	−2	−3	−4	−5	−6	−7	−8	−9

Here the minuend is **1** greater in each case.

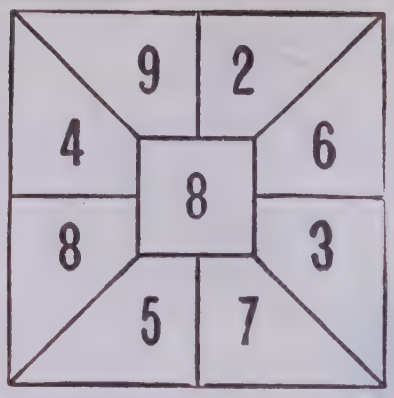
6. Teach the parts of **10**.

5	2	3	4	9
+5	+8	+7	+6	+1

7. In adding **9** to numbers have the child think of **9** as **10**

thus $\begin{matrix}9\\+6\end{matrix} = \begin{matrix}10\\+5\end{matrix}$ and $\begin{matrix}9\\+8\end{matrix} = \begin{matrix}10\\+7\end{matrix}$

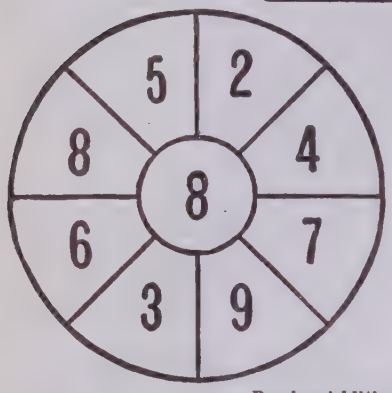
8. Teach the corresponding subtractions.
9. Add **8** to each number up to **10**.
10. Teach the corresponding subtractions.
11. Add **7, 6,** and **5** to each number up to **10**.
12. Teach the corresponding subtractions.
13. Review and give combinations not taught above.



Note.—Objects should be grouped by tens and units, in showing numbers above **10**. The numbers written should represent objects counted.

The Forty-Five Facts of Addition

1	2	2	3	3	4	3	4	5
1	1	2	1	2	1	3	2	1
2	3	4	4	5	5	6	6	6
4	5	6	4	5	6	7	5	6
3	2	1	4	3	2	1	4	3
7	7	7	8	8	8	8	9	9
7	8	5	6	7	8	9	6	7
2	1	5	4	3	2	1	5	4
9	9	10	10	10	10	10	11	11
8	9	6	7	8	9	7	8	9
3	2	6	5	4	3	6	5	4
11	11	12	12	12	12	13	13	13
7	8	9	8	9	8	9	9	9
7	6	5	7	6	8	7	8	9
14	14	14	15	15	16	16	17	18



Note.—Be sure that the nine facts underscored are thoroughly learned. They give most trouble.

Drills in Addition

Draw on a sheet of paper a large square and a circle. Divide them like these. Put, say the figure 8, in the center with the other numbers around it.

Write any figure in the center where the 8 is. Then drill, by pointing to the figures around it, while the child names at once the sum of the center figure and the one pointed at.

Use exercises like this frequently and give many problems, using the combinations with which you find the child has difficulty.

Exercises in which the child counts by 2's, by 3's, etc., to 100 are valuable.

Proving Addition

You may early teach how to prove an addition. There are a number of ways of doing this. Use the way the child's teacher uses. It is a good way.

One Way

Add the columns down. If the result is the same as when the columns were added up, the result is correct.

Second Way

Write the numbers in two groups. Find the sum of each group. Add the sums of the two groups. If the result is the same as when the numbers were added in one group, the result is correct.

Illustration of second way:—

273 }	—— 273	
456 }	456	
	729	729
629 }	—— 629	
384 }	384	
1742	1013	1013
		1742

The Accountant's Proof

This is a modification of the plan called *casting out the nines.*

Illustration

7926—24—6	}
4356—18—9	
1824—15—6 +	}31—4
9263—20—2	
7856—26—8	}
31225—13—4	

Explanation

First add the columns in the regular way. Add each column horizontally, left to right. The results are 24, 18, 15, etc. Add these horizontally and you have 6, 9, 6, etc.

You have now reduced all to one column. Take the sum of this column. It is 31. This added horizontally is 4.

Add the sum 31225 horizontally until you have but one figure in it and you also have 4. This proves your answer correct.

Another Illustration

This illustrates where it is necessary to carry the horizontal additions a step further:—

986745—39—12—3	}
726324—24— 6—6 +	}16—7
916348—31— 4—4	
992973—39—12—3	}
3622390—25— 7—7	

Note.—With some practice it will be necessary to write the last line of figures only.

Rapid Adding Exercises

When pupils have learned to add they quickly acquire skill by an occasional rapid adding exercise. A few minutes serves the purpose.

It may be made competitive by each pupil writing the numbers and at a given signal beginning the addition.

Slow and correct work is preferable to rapid work that is incorrect. Incorrect work is of no value here.

Civil Service Method of Adding

Employees under the civil service bureau, bank clerks and others who perform additions while surrounded by people engaged in conversation use the following method in their additions.

This method is safe because one can detect and change an error very quickly.

$5280	16
9760.50	21
349	19
4006.75	23
6522.89	18
132.12	24
	$26,051.26

The Banker's Method of Adding

This method is the same as that used by the civil service employees, with one change. In adding the columns the number carried is "added in" to each partial sum.

$5280	16
9760.50	22
349	21
4006.75	25
6522.89	20
132.12	26
	$26,051.26

The banker's method is an improvement on the civil service method as it does not require a second addition. The number to be carried is always in sight in the banker's method, being the tens figure of the last partial sum written. The sum can be written at once.

SUBTRACTION

The differences of all these combinations should be learned so thoroughly that the pupil will be able to name difference of any combination *on sight.* This will take time, but it is time well spent.

Use devices similar to those used in the drills on the addition table.

Give many problems for oral work. Let the pupil make many problems and give the difference in each case.

Combinations in Subtraction

—	—	—	—	—	—	—	—	—	—	—

The Computer's Method

In making change, the method below is nearly always used. Computers find it the more practical way. It gives greater rapidity and accuracy than the other method.

Many of the best teachers use it alone in teaching subtraction.

This plan is called the Austrian method by some.

Example

Find the difference between 725 and 432.

Work:

725	*Explanation*
——	Let the pupil imagine he is adding with the sum written above.
432	He inserts the missing figures to form the sum as he works, 3, 9, 2.
293	He thinks of 2 and 3 as 5; 3 and 9 as 12; 5 and 2 as 7. He may
——	talk it this way: 3 and 2, 5; 9 and 3, 12; 3 and 4, 7.

Use that method with these examples:—

42,936	2034	7825	6243
—17,245	—1456	—1504	—1428
25,691	578	6321	4815

Note.—With practice the pupil will come to prefer this method and should be helped in its use. It is practical since conducive to both *rapidity* and *accuracy.*

Proofs of Subtraction

To prove a subtraction *add* the *subtrahend* to the *remainder*. The result will be the *minuend* if the work is correct.

Example	*Proof*
425 *minuend*	173
—173 *subtrahend*	252
252 *remainder*	425

425 is the same as the minuend, hence the work is correct.

Another Proof

Take the remainder from the *minuend*. If the work is correct the subtrahend will be left.

If in the last example given we write

425
—252

we get **173**, which is the subtrahend used above, hence the work is correct.

Note.—Either proof may be used. Show the child why these two proofs are true. Use small numbers to do this like 7—2. Later use larger ones.

NUMBER STORIES IN MULTIPLICATION

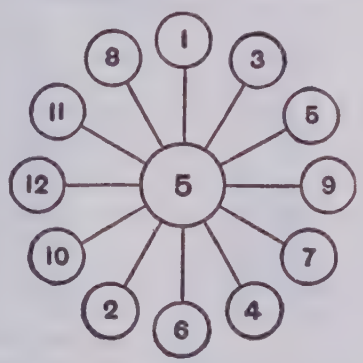
Example

$3 \times 4 =$—

Facts Given by Child

3 ×**4** means **3 4's.**
I count my blocks by fours—I take **1** four, another, another.
I find that **3 4's** are **12.**
3 ×**4** =**12.**

To the Teacher



Now the child is ready to give a number story about **3** ×**4.**

Note.—If the pupil is in doubt about any part of the work in number stories, he should use objects, and then practice much without them.

Drills in Multiplication

The drill opposite is very good and effective, if a rapid answering exercise is made of it. Products should be given at once.

To vary it use squares.

Draw a diagram like this one and let the pupil fill in the squares with the proper products. Fix a time limit. Have results put in quickly.

1	2	3	4	5	6	7	8	9
2								
3								
4						28		
5								
6								
7					42			
8								
9								
10								

4 X 1 = 4
4 X 2 = 8
4 X 3 = 12

Make diagrams like these, and let the pupils fill them in.

In this work it is not intended that the pupil should at first learn "his tables" in order, the 2's first, then the 3's, then the 4's, etc. He remembers many of the facts of multiplication from his primary work in numbers. These drills are to complete and fix firmly in the pupil's mind the completed multiplication tables.

7 X 1 = 7
7 X 2 = 14
7 X 3 = 21

Proofs in Multiplication

The Multiplication	*The Proof*
42	25
×25	×42
210	50
84	100
1050	1050
123	475
×475	×123
615	1425
861	950
492	475
58,425	58,425

The proof consists merely in reversing the positions of the multiplicand and multiplier, and performing the multiplication in the usual way. If the product is the same in both cases the work is correct.

PRIMARY IDEAS OF DIVISION

In teaching the two ideas of division—division by measurement (division proper) and the fractional idea of division (partition)—proceed very slowly and see that each step is thoroughly understood.

The following suggestions may be useful:—

Division by Measurement

Use colored blocks or any other counters in illustrating the process.

Example

4)12

The teacher should ask the child, "How would you count this story?"

Facts Given by Child

12 =whole number of blocks.
4 =number in each part.
We want to know the number of parts.
We place the blocks so, **4** in each part:—

There are **3** parts.

Division by Partition

Make use of colored blocks or substitutes to show the process here.

Example

¼ of **12** =**3**

The teacher should ask the child, "How would you count this story?"

Facts Given by Child

12 =whole number of blocks.
4 =number of parts.
We want to know the number in each part.
We place the blocks so, as we know there are **4** parts:—

We have put one in each part.
Now we will put one in each part until the **12** blocks are gone:—

There are **3** in each part.

The Three Uses of Division

First Use Explained (Partition)

What is ¼ of 24 cents?

Here 24 cents is the sum of money to be divided. It is to be divided by 4. The result shows the size of each part.

Number of equal parts **4**) **24**c money to be divided.

6c size of each part.

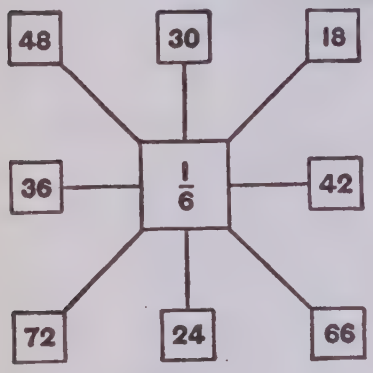
Second Use Explained (Division by Measurement)

How many times is 8 cents contained in 32 cents?

Here 32 cents is the sum of money to be divided. The size of each part is 8 cents, and the result gives the number of equal parts.

Size of each part 8c) 32c money to be divided.

4 number of equal parts.



Third Use Explained (Ratio Idea)

There are 36 acres in one lot and 9 acres in another. The first lot is how many times as large as the second?

From division we know that 36 acres contains 9 acres 4 times. Then 36 acres is 4 times as large as 9 acres; or, 36 acres is to 9 acres as 4 acres is to 1 acre.

Note.—This on the ratio idea leaves the impression that the other work does not embrace the ratio principle. Any comparison of numbers embraces the ratio idea.

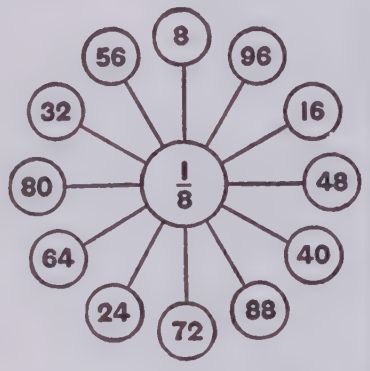
Division Drills

It is well to use drills of different kinds to help fix the facts of the division table in mind. At no time, at this stage, are you sure that the pupil remembers from one day to the next.

Diagram drills are given here as suggestive of what may be made use of. Use other numbers in order to get drill on the whole division table.

Be sure to make the drill work brisk and of short duration.

The Drill



The teacher points to any of the numbers in the small squares and the child answers simply the quotient number. Skip about rapidly. Draw the same diagram on the blackboard and frequently change the fraction in the center square.

The Drill

Allow no "thinking out" of results. The child should have the table at his tongue's end.

Change center fraction repeatedly.

The supreme test of his mental activity is to think quickly and tell correctly.

Proofs in Division

The best way to prove work in division is to multiply the quotient by the divisor and add the remainder, if there is one.

The result will equal the dividend if the work is correct.

Example

Divide 600,181 by 937.

Work

640 501/937

937)600181
5622
3798
3748
501

Proof

600181

READING NUMBERS

When we spell a word, that is, when we read the letters in the word, we read from *left to right.*

To read a number we do the same thing for we read the figures from left to right.

325 is read "three hundred twenty-five."

The number is read differently if we wish to tell the *place* and *value* of a certain figure, for then we read the figures themselves from *right to left.* thus—

325 means 5 units, 2 tens, 3 hundreds.

Never use "AND" in reading whole numbers.

325 should never be read "three hundred and twenty-five," but "three hundred twenty-five."

Numbers between 100 and 1000 are read by naming the hundreds, tens, and units in succession. Thus—

192—one hundred ninety-two.
652—six hundred fifty-two.
207—two hundred seven.

Above 1000

Read 1,892,632.

Here the 2 represents 1's, or units of the *first order.*
the 3 represents 10's, or units of the *second order.*
the 6 represents 100's, or units of the *third order.*
the 2 represents 1000's, or units of the *fourth order.*
the 8 represents 100000's, or units of the *sixth order,* etc., etc.

The order of any figure is the number of its place, starting from the right.

In reading large numbers we arrange the orders into groups of three figures each.

We call each group a *period.* Commas are used to keep the periods separate.

Names of the Periods

units,	billions,	quintillions,	octillions,
thousands,	trillions,	sextillions,	nonillions,
millions,	quadrillions,	septillions,	decillions.

trillions	billions	millions	thousands	units
225,	902,	302,	472,	399.

FACTS ABOUT ROMAN NUMERALS

The following facts about the origin and development of Roman notation can be made very interesting, and will tend to fix the characters in one's mind—

At first one	was written	I,
two	was written	II,
three	was written	III,
four	was written	IIII,
five	was written	IIIII,
six	was written	IIIIII,
seven	was written	IIIIIII,
eight	was written	IIIIIIII,
nine	was written	IIIIIIIII.

It took too long to make ten marks, and too long to count them after they were made, so one mark with another across it was used to denote 10, thus **X.** The upper or first half of the **X,** or **V,** was used to show 5.

At first twenty	was written	XX,
thirty	was written	XXX,
forty	was written	XXXX,
ninety	was written	XXXXXXXXX.

It took too long to make the crosses and too long to count them in reading, so **D** was used to show 100. Half of the **D** or **L** was used to show 50. The **D** gradually became **C** in trying to make the **D** rapidly.

Write these where the child can see them plainly

I = 1	XX = 20	XXXIX = 39
II = 2	XXI = 21	XL = 40
III = 3	XXII = 22	XLI = 41
IV = 4	XXIII = 23	XLII = 42
V = 5	XXIV = 24	XLIII = 43
VI = 6	XXV = 25	XLIV = 44
VII = 7	XXVI = 26	XLV = 45
VIII = 8	XXVII = 27	XLVI = 46
IX = 9	XXVIII = 28	XLVII = 47
X = 10	XXIX = 29	XLVIII = 48
XI = 11	XXX = 30	XLIX = 49
XII = 12	XXXI = 31	L = 50
XIII = 13	XXXII = 32	LX = 60
XIV = 14	XXXIII = 33	LXX = 70
XV = 15	XXXIV = 34	LXXX = 80
XVI = 16	XXXV = 35	XC = 90
XVII = 17	XXXVI = 36	C = 100
XVIII = 18	XXXVII = 37	D = 500
XIX = 19	XXXVIII = 38	M = 1000

PRIME NUMBERS

Some numbers, like 3, 5, 11, etc., can only be divided by themselves and unity. As they cannot otherwise be factored, we call them *prime numbers.*

Prime Numbers from 1 to 1000

(Use This Table for Reference)

1	59	139	233	337	439	557	653	769	883
2	61	149	239	347	443	563	659	773	887

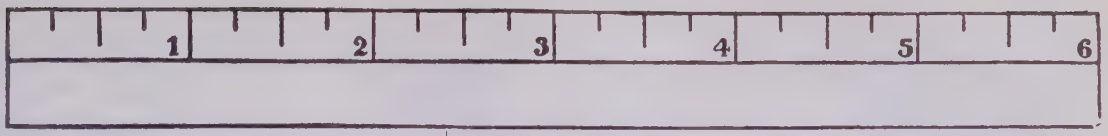
SIMPLE MEASURES—For the Child to Learn Objectively

2 pints make 1 quart.
8 quarts make 1 peck.
4 pecks make 1 bushel.
7 days make 1 week.*
16 ounces make 1 pound.
12 inches make 1 foot.
3 feet make 1 yard.
12 things make 1 dozen.
5 cents make 1 nickel.
10 cents make 1 dime.

LONG MEASURE

Teach the child to estimate distances and then to verify every estimate by actual measurement.



Teach half inches as well as inches.

For the Child to Do

1. Cut a strip of paper 12 inches long and 1 inch wide.
2. Mark the inches on it.
3. How many inches long is it?
4. What do you call a measure 12 inches long?
5. Draw a line 2 inches long, as near as you can, without using a ruler.
6. Measure it with a ruler. Did you guess nearly right? Try again.
7. Measure this page. How long is it? How wide?
8. Draw a line on the ground 1 yard long.
9. ½ of a foot is how many inches?
10. 1 yard is how many inches? What is measured by the yard?

*Objectively so far as pointing it out on a calendar.

11. Ask your mother how many yards of cloth she needs for a dress.
12. What is measured by the foot?
13. How tall are you?

PRIMARY IDEAS OF TIME

Turn to the paragraph on Roman numerals and note the facts about them.
60 minutes make 1 hour.
12 hours make 1 half day.
24 hours make 1 day.

A new day begins at midnight and lasts until next midnight.

One hour after midnight is 1 o'clock, 2 hours after midnight is 2 o'clock, and so on, until 12 o'clock at noon.

At noon one-half the day has gone and we begin the afternoon, which is the last half of the day.
One hour after noon is 1 o'clock, 2 hours after is 2 o'clock, etc.

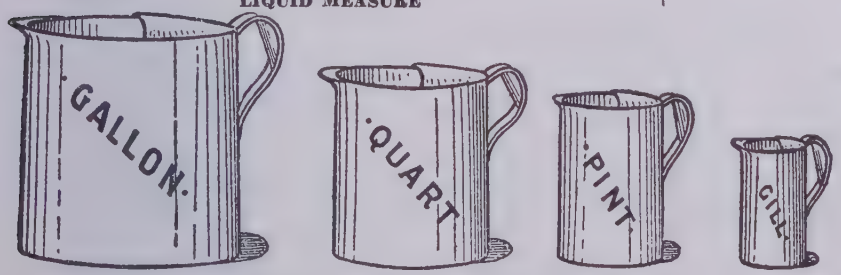
If a person says he was at a certain place at 2 o'clock, he must say forenoon or afternoon, so we will know which half of the day he means. If it was 2 o'clock in the morning he would write 2 a. m., and if 2 o'clock in the afternoon, 2 p. m.

How to Teach a Child to Tell Time

First—Teach him to tell the hour hand from the minute hand.
Next—Teach him when he first looks at the dial, to find the hour hand and then notice which Roman numeral it is nearest. *This will tell about what time it is.*

Then—Find the minute hand. *The minute hand will tell exactly what time it is.*

To Illustrate



Take this clock. The hour hand is near the Roman numeral II, which stands for 2. Tell the child it is somewhere near two o'clock.
The minute hand will tell *how near.*

It must always point to the XII before it is exactly the hour. If it is one numeral away from the XII, toward the left, it is 5 minutes of two. If it is two numerals away to the left, it is 10 minutes of two, etc. If it is one numeral away to the right, it is 5 minutes after two, etc. Proceed in this way and keep at it.

LIQUID MEASURE

If you have quart and pint measures allow the child to empty water from one to the other.
On teaching the table of liquid measure proceed in this manner—
Here is a gill cup. I am going to fill it to see how many gills make a pint. Now I have poured one gill; now two; now three; now four. Is the pint cup full? How many gills in a pint?
Let us prove what you say by pouring the water back. One gill; two gills; three; four. Were we right then?
Let us write what we have just said and proved—
4 gills = 1 pint.
Proceed in this way with the other measures, only let the child do more of the work for himself.

MONEY

Use actual coins in teaching money. Lessons on money should be given frequently after the first year of school life.
Begin by teaching the value of the cent and the nickel, then the dime, then the quarter, then the half-dollar, and then the dollar.
Make problems involving change. Develop the ability to make change rapidly. The child may have some money of his own and he should be taught the comparative values of the coins. The correct method of making change follows.

10 cents make 1 dime.
2 five-cent pieces make 1 dime.
100 cents make 1 dollar.
A quarter of a dollar = 25 cents.
A half-dollar = 50 cents.
$ means dollars and *c* means cents.
A 5-cent piece is called a nickel because it is made of nickel.
A cent piece is made of copper.
The other coins named are made of silver.

HOW TO MAKE CHANGE

First—Name the cost of goods.
Then—Add enough money to make even money.
Last—Add the large coin.

To Illustrate

I bought some cloth for 35c and gave the clerk 50c. Count my change.
How to count it—
35c for cloth
And 5c makes 40c (to make even money)
And 10c makes 50c.

To Illustrate

I buy suspenders for 32c and give the clerk $1. Count my change.
How to count it—
32c for suspenders
And 3c makes 35c
And 5c makes 40c
And 10c makes 50c
And 50c makes $1
(to make even money)

Note.—Think of it in this way—32c, 35c, 40c, 50c, $1.

THE CALENDAR

Procure a calendar for the child to own.

A good way to make him familiar with the use of the days of the week and month, as found on a calendar, is to ask him to look up and tell on what day of the week the next Fourth of July will fall; Christmas; New Year; his birthday.

Have him distinguish between the day of the week and the day of the month.

1934 August 1934

Sun.	Mon.	Tues.	Wed.	Thur.	Fri.	Sat.
First Quar. 1st 30th	Full Moon 9th	Last Quar. 17th	1	2	3	4
5	6	7	8	9	10	11
12	13	14	15	16	17	18

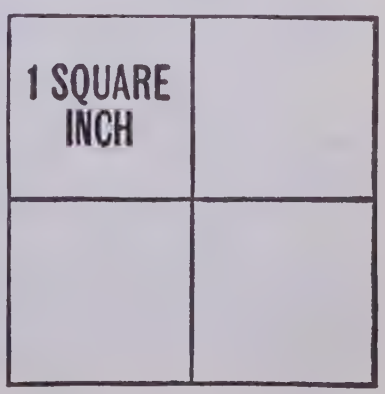
SQUARE MEASURE

How long is each side of the figure opposite?



How many squares in the figure?

Because each square is one inch on each side, we call it a square inch.

How many square inches in the whole figure?

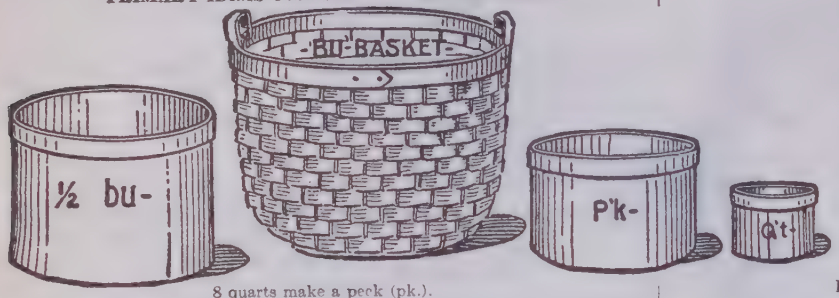
The number of squares is called the *area.*

4 square inches is the *area* of this figure.

Show by a drawing how many square inches in a figure 3 in. wide and 9 in. long.

Its area is 27 square inches.

We need not always draw a figure to get the area.



You will notice that the *length times the width will give the number of squares in the figure.*

Find the area of a figure 9 in. long and 5 in. wide, without a drawing. What did you do? *Make a rule.*

Cut out a piece of paper 1 in. wide and 4 in. long. Cut it into square inches. Place the cut squares so as to form a large square. How long is it now? How wide?

(*See section on weights and measures for advanced tables.*)

PRIMARY IDEAS CONCERNING DRY MEASURE

8 quarts make a peck (pk.).

4 pecks make a bushel (bu.).

Dry measure is sometimes used to measure dry articles. Formerly grains, vegetables, and fruits of all kinds were bought and sold by dry measure.

Don't teach the child, as most arithmetics say, that grains, fruits, and vegetables are bought and sold by the measured bushel. They are not.

The weight bushel, the case, and the box have come into common use for these articles.

Teach the names of the measures before you attempt to teach the number of one measure in another, etc.

SIMPLE FRACTIONS

A very good method of teaching the combinations in small fractions is by the use of paper or cardboard disks. (Children may call them circles.)

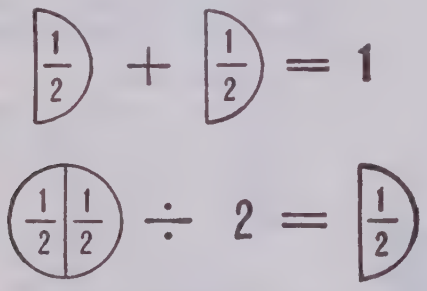
Cut out a large number of them, and, in order to avoid trouble later on, it might be better to have the disks all of one size—about 4 inches in diameter.

Teaching the Fraction $\frac{1}{2}$ with Disks

Say to the child:

I am going to cut this circle into two equal parts. What is this part called? What is this other part called? How many halves in the whole circle? One-half and one-half are what? One-half taken away from one leaves what? If I take a half *two times*, what do I get? How many halves in a whole?

Now I will write these—



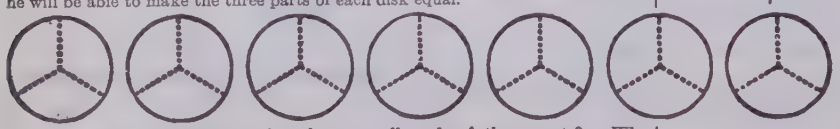
$\frac{1}{2} + \frac{1}{2} =$ 1 divided by $\frac{1}{2} =$

1 less $\frac{1}{2} =$ $1 \div 2 =$

$2 \times \frac{1}{2} =$ $1 - \frac{1}{2} =$

Give me the answers and I will write them.

Drawings showing the "placing" of disks for number stories can be made by the child; as,



Ask the child to make similar drawings to tell about halves.

Proceed like this—How many halves in a pie? If a pie cost 10 cents, what will half a pie cost? Who can tell other stories about halves? etc.

Teach fourths along with halves.

Teaching the Fraction $\frac{1}{3}$ with Disks

Cut several disks into thirds. Have the child practice on cutting, so that he will be able to make the three parts of each disk equal.

Then proceed like this—What do you call each of these parts? Why are they called *thirds*? How many thirds in a circle? I am going to take a circle and cut it any way, so as to make three parts; do I call these unequal parts thirds? Why not? Let me write one-third on a piece of paper for you. (Write, ⅓.) Draw a circle for me. Instead of cutting it, draw lines where you would cut it to make thirds. Write one-third (⅓) on each third of a circle. I write this (⅓+⅓). Who can tell me what the answer is? Are two-thirds and two-thirds more than one? How much more? I have two-thirds of an apple and give Mary one-third, how much have I left? Who can give other story problems about thirds? Everybody try, etc.

Teach sixths along with thirds. Use disks, dots, marks, sticks, and inches to illustrate.

Remember that no advance should be made until each little part is understood.

Teaching the Fraction $\frac{1}{5}$ with Disks

Have fifths compared with fourths, thirds, and halves.

Be sure that the child sees that the number below the line shows the size of each part and the number above how many parts are taken.

Have the child illustrate every step with drawings. If at any time he cannot answer results at sight, let him show the work with disks.

Say to the child:

I am going to cut this circle into five equal parts. What is each part called? How many fifths in the whole circle? How many fifths here? (Show two-fifths.) One-fifth and one-fifth are how many fifths? One less two-fifths is what? If I take three-fifths, how many times one-fifth do I take? How many times one-fifth are left? Are two-fifths greater than one-third?

Give and ask for story problems and number stories telling about fifths.

Teach tenths along with fifths.

When twelfths are taught, show the relations between twelfths and sixths, fourths, thirds, and halves.

Equal Fractions in Different Forms

Have the child see how fractions may differ in form but still remain the same in value.

Begin with his knowledge of smaller fractions, as

$\frac{1}{2}, \frac{2}{4}, \frac{3}{6}, \frac{4}{8}$, and $\frac{5}{10}$ of an apple

Let him show by the use of drawings that fractions may have large or small terms but be equal in value.

Things for the Child to Do

Fill out the numerators in the following fractions and prove each by a drawing:—

1. $\frac{1}{4} = \frac{2}{8} = \frac{4}{16} = \frac{8}{32} = \frac{16}{64}$
2. $\frac{1}{5} = \frac{?}{10} = \frac{?}{15} = \frac{?}{20} = \frac{?}{30}$
3. $\frac{1}{8} = \frac{?}{16} = \frac{?}{24} = \frac{?}{32} = \frac{?}{40}$
4. $\frac{3}{4} = \frac{?}{8} = \frac{?}{12} = \frac{?}{16} = \frac{?}{24}$
5. $\frac{2}{5} = \frac{?}{10} = \frac{?}{15} = \frac{?}{20} = \frac{?}{40}$

PRINCIPLES OF FRACTIONS

1. A fraction's value is the quotient obtained by dividing the numerator by the denominator.

$\frac{6}{2} = 3$ 3 is the value of $\frac{6}{2}$

$\frac{2}{3} = \frac{2}{3}$ $\frac{2}{3}$ is the value of $\frac{2}{3}$

2. Multiplying the denominator of a fraction divides the fraction by that number.

$\frac{1}{2 \times 4} = \frac{1}{8}$ $\frac{3}{7 \times 3} = \frac{3}{21}$ $\frac{2}{3 \times 9} = \frac{2}{27}$

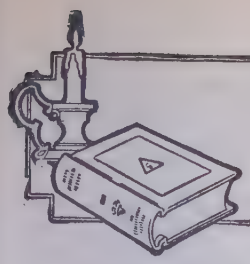
3. Dividing the denominator of a fraction multiplies the fraction by that number.

$\frac{3}{8 \div 4} = \frac{3}{2}$ $\frac{10}{9 \div 3} = \frac{10}{3}$ $\frac{3}{10 \div 5} = \frac{3}{2}$

4. Multiplying the numerator of a fraction multiplies the fraction by that number.

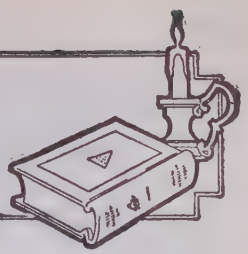
$\frac{2 \times 2}{3} = \frac{4}{3}$ $\frac{1 \times 8}{9} = \frac{8}{9}$ $\frac{5 \times 3}{8} = \frac{15}{8}$

5. Dividing the numerator of a fraction divides the fraction by that number.



$\frac{4 \div 2}{7} = \frac{2}{7}$ $\frac{12 \div 12}{16} = \frac{1}{16}$ $\frac{3 \div 3}{7} = \frac{1}{7}$

6. Multiplying both numerator and denominator of a fraction by the same number does not change the value of the fraction.



$\frac{1 \times 3}{3 \times 3} = \frac{3}{9} = \frac{1}{3}$ $\frac{6 \times 2}{7 \times 2} = \frac{12}{14} = \frac{6}{7}$

7. Dividing both numerator and denominator of a fraction by the same number does not change the value of the fraction.

$\frac{12 \div 3}{15 \div 3} = \frac{4}{5} = \frac{12}{15}$ $\frac{18 \div 9}{27 \div 9} = \frac{2}{3} = \frac{18}{27}$

Grammar School Arithmetic

APPLIED ARITHMETIC

In this section, arithmetic is presented in brief form for the aid of the busy student. Special emphasis is placed upon short methods and devices for checking results. Solutions of typical problems and tables are presented for review and aid in solving similar problems in business and school.

ADDITION

Addition is the process of combining numbers into a single equivalent number, called the sum, the amount or the total.

More than nine-tenths of the arithmetical work of a bookkeeper and business man consists in combining or adding numbers. To become successful as an accountant, cashier or clerk it is most essential that the ability to add be developed in a high degree. By constant drill one may become expert in adding units in rotation as follows:

(*A*)	(*B*)
4	42
8	24
2	36
6	72
7	81
27	255

In the above examples the worker simply runs up the columns taking one figure at a time as follows: 4 plus 8 equals 12, plus 2 equals 14, plus 6 equals 20, plus 7 equals 27, or the sum. The same operation would be carried out in the case of problem (*B*) with the exception of *after* obtaining the sum of the first column to the right to be 15, the worker puts the figure 5 under the column and adds the 1 to the next column to the left, making the sum of that column 25 and the total sum 255.

However, this method is slow and cumbersome and no one can hope to acquire great speed in addition who has to depend upon it.

Group Method.—In adding columns of figures it is advisable to group the numbers into totals as one proceeds up and down the columns. In the above problem (*A*): In adding 4, 8, 2, 6, and 7, think of each subtotal as follows: 12 (4 plus 8), 20 (2 plus 6 added to previous sub-total) and 27. The method rests on the ability to group two or more numbers together at a glance:

6 5 4 3 } equals 12
6 7 8 9 }
2 3 4 5 } equals 11
9 8 7 6 }

Thus in adding the following:

(*A*)	(*B*)	
8 3	3	(*A*) Read instantly the numbers in brackets as: 8, 9, 7, 8, and 7. When combining, read as follows: 8, 17, 24, 32, and 39.
5	10 5	
9 2	2	
7	5	
7 4	10 4	
3	1	(*B*) Process is same as in (*A*) except that three are joined instead of two. Should be read as follows: 10, 20, 27.
6	2	
8 2	7 2	
7	3	
39	27	

This may be carried to almost any extent; *e. g.*,

53 The worker should think in groups
27 of 10, as follows:
— 53, 63, 83, 80.
80

Some bookkeepers regularly add double columns after the above plan, or some variation of it. Thus in adding 56 and 67, he would think 50 plus 60 plus 6 plus 7.

All addition should be checked or tested by one of the following methods:

(*a*) Reverse addition; that is, adding down after adding up.

(*b*) After adding by consecutive numbers or group, check by adding in group by tens.

(*c*) Add the unit column and write the total to one side as in the following example:

3967	
8234	27
7987	32
4372	31
5976	26
30536	30536

The above is obtained by first adding the units' column and writing the sum, 26, to the right. Next add the tens' column and write the sum as shown above. The sums of the hundreds' and thousands' columns, 32 and 27, are written as shown. Beginning with the units' column and adding, the result agrees with that of the problem.

(*d*) Casting or counting out nines. This means add the digits in the number and whenever the sum equals or exceeds 9, discard 9, adding the remainder to succeeding digits.

426—3
824—5
936—0
1542—3
3728—2 check remainder.

Explanation: Take the first number, 426, the excess of the sum of the digits over nine is 3. Doing the same with the remaining digits and dividing by nine, we find the excess or final remainder. The sum of the digits in the sum, 3728, is then divided by nine and we find a remainder of 2. Adding the remainders to the right, the sum is 11. Dividing 11 by 9, we find a remainder of 2. If the final remainder equals the remainder of the sum, the sum may be presumed to be correct.

(*e*) Casting out elevens:

426—6 plus 4 minus 2 = 8
824—4 plus 8 minus 2 = 10
936—6 plus 9 minus 3 = 12
1542—2 plus 5—4— 1 = 2 32
3728—8 plus 7—3— 2 = 10

The sum of 8 plus 10 plus 12 plus 2 is 32, and 32 is two 11s' and 10 over.

Explanation: Find the sum of the digits in the odd places, beginning at units, and from it deduct the sum of the digits in the even places. In case the sum of the digits in the even places exceeds the sum of the digits in the odd places, add 11 to the sum of the digits in the odd places.

SUBTRACTION

Definition.—Subtraction is the process of finding the difference between two numbers.

Minuend, Subtrahend, Remainder, Sign of Subtraction.—In the example, 9 minus 7 equals 2, 9 is the minuend; 7 is the subtrahend, and 2 is the remainder. The sign of subtraction is —.

Use.—"Making change" is the simplest and most frequent use of subtraction in business. It is also used in finding the balance of accounts, finding the bank balance, and in finding profits or losses.

Subtraction is but a phrase of addition. The so-called Austrian or "Making change" method is the one most commonly used in the elementary schools today. It is the process of finding the number to be added to the lesser number in order that the sum may equal the greater.

Illustration:

Find the difference between 742 and 1937.

1937 Add to the subtrahend, digit by
742 digit until the minuend is obtained,
— thus: 2 (subtrahend) plus 5 = 7
1195 (minuend). Write the 5 as a unit difference. 4 (subtrahend) plus 9 = 13 (minuend). Write the 9 in tens' place and add the 1 to the 7 (subtrahend). 7 plus 1 = 8 (subtrahend) plus 1 = 9 (minuend). Write the 1 in hundreds' place of difference. 0 (subtrahend) plus 1 = 1 (minuend).

It is often more practical to place the lesser number above the greater, thus bringing out the process more concretely. The above example might be written:

742
1937
—
1195

MULTIPLICATION

Uses.—Multiplication is continually used in business. Probably it stands next to addition in the frequency of use. For this reason it should be thoroughly mastered by everyone who wishes to become a successful clerk, accountant or business man in any capacity. Very frequently situations arise when it is necessary for the business man to perform mental multiplications quick and accurately.

Definitions.—MULTIPLICATION, MULTIPLIER, MULTIPLICAND. Multiplication is the process of taking one number, called the multiplicand, as many times as the number one is contained in another number, called the multiplier.

—PRODUCT. The result obtained by multiplication is called the product.

—FACTORS. The multiplier and the multiplicand are called the factors of the product.

Example: 2×4=8. In this example, 2 is the multiplier; 4 is the multiplicand; 8 is the product, and 2 and 4 are the factors of 8.

MULTIPLICATION TABLES—All multiplication is based upon the multiplication of the numbers from one to ten, inclusive. In a large majority of the cases of multiplication in business, the factors are small numbers and the multiplication

should be performed mentally. This is especially true in billing. For this reason both the basic and supplementary tables given below should be perfectly memorized.

BASIC TABLE

	2	3	4	5	6	7	8	9	10
1	2	3	4	5	6	7	8	9	10
2	4	6	8	10	12	14	16	18	20
3	6	9	12	15	18	21	24	27	30
4	8	12	16	20	24	28	32	36	40
5	10	15	20	25	30	35	40	45	50
6	12	18	24	30	36	42	48	54	60
7	14	21	28	35	42	49	56	63	70
8	16	24	32	40	48	56	64	72	80
9	18	27	36	45	54	63	72	81	90
10	20	30	40	50	60	70	80	90	100

SUPPLEMENTARY TABLE

11	22	33	44	55	66	77	88	99	110
12	24	36	48	60	72	84	96	108	120
13	26	39	52	65	78	91	104	117	130
14	28	42	56	70	84	98	112	126	140
15	30	45	60	75	90	105	120	135	150
16	32	48	64	80	96	112	128	144	160
17	34	51	68	85	102	119	136	153	170
18	36	54	72	90	108	126	144	162	180
19	38	57	76	95	114	133	152	171	190
20	40	60	80	100	120	140	160	180	200

The process of multiplication is indicated by placing the sign × between the two numbers, thus: 5×7=35. This is read: Five times seven equals 35.

Multiplying by 10 or a Multiple of 10.—It is inherent in the decimal system of notation that the placing of a zero to the right of a number multiplies that number by ten; for example, 20 is ten times as great as 2; 200 is ten times as great as 20, etc. Therefore in multiplying by 10 or a multiple of ten it is only necessary to multiply by the integer or integers of value and add as many zeros as there are in the multiplier; e. g., 2000×68=136,000. (2×68=136; adding the three zeros of the 2000 gives the answer).

Multiplication Illustrated.—Multiply 4362 by 243. The process of performing this operation is as follows: (1) Multiply by the 3; (2) multiply by the forty represented by the 4 in the tens' place; (3) multiply by the 200 represented by the 2 in hundreds' place; (4) add the products; thus:

(*A*)		(*B*)		(*C*)	
4362		4362		4362	
243		243		243	
13086	(1)	13086	(1)	8724	(3)
174480	(2)	17448	(2)	17448	(2)
872400	(3)	8724	(3)	13086	(1)
1059966	(4)	1059966	(4)	1059966	(4)

In practice the zeros at the end of (2) and (3) are omitted and the work appears as in (*B*).

It is not absolutely necessary to begin with the units digit of the multiplier. By beginning with the highest order the work will appear as in (*C*). This method is sometimes advantageous.

When two numbers are to be multiplied, either may be taken as the multiplier. It is usually better to use the smaller as the multiplier. When one of the numbers contains 1's or 2's or two or more digits alike, it is easier to multiply by that number. In finding the cost of 748 machines at $112 each, use 112 as the multiplier.

When one of two numbers to be multiplied contains one or more zeros, that number should be taken as the multiplier. The product of zero and any number is zero. In example (*D*), since the products of the tens' and hundreds' places are zero, the results need not be written.

(*D*)

6348
1005
31740
6348
6379740

Checking Multiplication.—There are a number of methods by which multiplication may be checked. The most practical and commonly used ones follow:

1. By interchanging the factors; i. e., by taking the multiplicand as the multiplier in repeating the multiplication. (*A*)

2. By division. Dividing the product by either factor will give the other factor. (*B*)

3. By casting out 9's—sometimes called excess of 9's. (*C*)

4. By casting out 11's—sometimes called excess of 11's. (*D*)

(*A*)

45	36
36	45
270	180
135	144
1620	1620

(*B*)

45	45)1620(36
36	135
270	270
135	270
1620	

(*C*)

2345— 5	The excess of 9's in
317— 2	the multiplicand is 5.
16415 10—1	The excess of 9's in
2345	the multiplier is 2.
7035	The product of the
743365—1	excesses is 10 and the excess of 9's in this product is 1. The

excess of 9's in the product in the example is 1. THE EXCESS OF 9's IN THE PRODUCT IS EQUAL TO THE EXCESS OF 9's IN THE PRODUCT OF THE EXCESSES. (Explanation of finding excess of nines is given under Checking Addition).

(*D*)

2345— 2	The excess of 11's in
317— 9	the multiplicand is 2
16415 18—7	(5 minus 4 plus 3
2345	minus 2 equals 2).
7035	The excess of 11's in
743365—7	the multiplier is 9. (7 minus 1 plus 3 equals 9). The prod-

uct of these excesses is 18 and the excess of 11's in 18 is 7. The excesss of 11's in the product is 7. (5 plus 11 minus 6 plus 3 minus 3 plus 4 minus 7 equals 7). (The finding of the excess of 11's is explained under the checking of addition).

The first two of these checking methods are practical only when the factors are small. When the factors of the multiplication are large numbers the last two methods should be used. The casting out of either nines or elevens alone is not an absolute check but when the two are used together the possibility of error is so small as to be practically negligible.

Short Methods of Multiplication.—To multiply by 10, 100, 1000, etc. When the multiplicand is an integer, annex as many zeros as there are in the multiplier; e. g., 10×75=750; 100×75=7500. When the multiplicand is a decimal, move the decimal point as many places to the right as there are zeros in the multiplier; e. g., 100×.75=75.

To multiply numbers ending in zeros: When both the multiplicand and multiplier are integers, multiply by the significant figures and annex as many zeros as there are in the endings of both multiplier and multiplicand; e. g., 220×400 equals 4 times 22 with three zeros added to the right. When one of the numbers is a decimal fraction, multiply the significant numbers and move the decimal point as many places to the right as there are zeros in the ending of the integer. Thus: .256×200. .256×2=.512; moving the decimal point two places to right makes the answer 51.2.

To multiply by 21, 31, 41, etc. This can best be explained by taking an example, as 234×21=4914. The process is as follows: The first figure on the right is evidently 4; 2×4 plus 3 (1×3) equals 11. Write 1 and carry 1. 2×3 plus 1 (carried) plus 2 (1×2) equals 9, the third figure. 2×2 equals 4, the fourth figure in the product.

This same method of solution can be used in multiplying by 101, 201, 301, etc. In the example, 432×201=86832, it is evident the first two figures of the product are 32. Multiplying and adding, 2×2=4 plus 4 (1×4) equals 8, the third figure. Completing the multiplication by 2, the fourth figure is 6 and the fifth, 8.

To multiply by 9, 99, 999, etc. To multiply by 9, annex one zero to the multiplicand, thus multiplying it by 10. From this result subtract the number to be multiplied. Multiply 348 by 9.

Solution: 3480
348
3132

To multiply by 99, annex two zeros to the multiplicand, thus multiplying it by 100, and subtract the multiplicand. 348×99=34800−348=34452.

This same method of solution may be applied to multiplications by 19, 29, 39, etc., by multiplying by the significant figure, adding a zero and subtracting the number to be multiplied.

This short method may also be extended to multiplication by any number slightly less than 100, 1000, 10,000, etc. The method of multiplying by 101, 201, etc. may be extended to multiplication by any number slightly more than 100, 1000, 10,000, etc.

Multiply 321 by 997=321,000−963=320,037.

Multiply 321 by 102=32742.

To multiply by 11 or multiples of 11. The first figure of the product is the first figure of the multiplicand; the second figure of the product is the sum of the first and second figures of the multiplicand; the third figure of the product is the sum of the second and third figures of the multiplicand, etc. In case the sum of two figures is ten or more, the 1 must be carried. Multiply 247 by 11: The first figure is 7; the second figure is the sum of seven and 4, 11; the third figure is the sum of the 1 (carried) 4 and 2, 7; and the fourth figure is 2. The product is 2717. In the case of multiples of 11, multiply by 11 first mentally and then multiply that product by the factor necessary to produce the multiplier. Multiply 247 by 33: 11×247=2717. 3×2717=8151.

To multiply by 111: Multiply 132,476 by 111: By inspecting the solution by the ordinary method, it will be seen that the first figure in the product is the first figure in the multiplicand. The second figure in the product is the sum of the units' and tens' figures in the multiplicand; the third figure in the product is the sum of the units', tens' and hundreds' figures in the multiplicand; the fourth figure in the product is the sum of the tens', hundreds' and thousands' figure in the multiplicand, etc. When the sum is ten or more the tens' digit in the sum must be carried to the next sum.

132476
132476
132476
14704836

To multiply two numbers ending in 5: First case: When the sum of the digits to the left of the 5's is an even number. Rule: Set down 25 as the first part of the product. To the product of the digits to the left of the 5's add ½ their sum. Write this amount before the 25. Example: Multiply 65×45. Since the sum of 6 and

4 is even, 25 is the first part of the product. 6×4 plus ½ (6 plus 4) = 29. Setting the 29 before the 25, the product is 2925.

Second case: Rule: Set down 75 as the first part of the product. To the product of the digits to the left of the 5's add ½ their sum, disregarding the fraction. Example: 85×135. Since the sum of 8 and 13 is odd, 75 is the first part of the product. 8×13 plus ½ (8×13) = 114½. Drop the ½ and write 114 before the 75. The product is 11475.

To square any number of two figures. Multiply 32 by 32. The solution of this problem is based upon the algebraic solution of the problem $(a+b)^2=a^2+2ab+b^2$. The number 32, is composed of the two parts, 30 or 3 tens plus 2 units. Taking the formula from right to left the steps are as follows: (1) Square the units' digit and write this as the first figure in the product; in this case 4. (2) Multiply the product of the units' and tens' digit by 2 and write this as the second figure in the product. (3×2 equals 6; 2×6 equals 12. Write the 2 as the second figure and carry the 1). (3) Square the tens' digit and add any figure "carried". (3×3=9; 9 plus 1 equals 10. Write the 10 as the last part of the product. 1024 is the product).

To multiply by 25, 50, 75, 125, 250, etc. 25 is ¼ of 100. Multiplying by 100 gives a product four times as great as multiplying by 25. Therefore, to multiply by 25, annex two zeros to the multiplicand (thus multiplying by 100) and divide the result by 4. To multiply by 50, annex two zeros to the multiplicand and divide the product by 2. To multiply by 75, annex two zeros to the multiplicand and divide by 4, and multiply the result by 3.

125 is ⅛ of 1000. Hence, to multiply by 125, annex three zeros to the multiplicand and divide by 8. 250 is ¼ of 1000. Hence, to multiply by 250, annex three zeros and divide the result by 4.

(For further application of aliquot parts of 10, 100 and 1000 to multiplication, see Aliquot Parts.)

To multiply when one figure of the multiplier is a factor of the other figure or figures of the multiplier. Multiply 426 by 279. It will be noticed that 9 is a factor of 27. Therefore, multiply by 9 and then multiply this result by 3.

```
  426
  279
  ---
 3834   9×426
11502   3×3834
------
118854
```

Cross multiplication. This method is practical only for multiplication by a multiplier of two figures. With practice a high degree of speed and accuracy can be acquired. Multiply 43 by 27. 43×27 = 1161. (1) 3×7=21; write 1 and carry 2. (2) 7×4 plus 2 (carried) = 30; 2×3=6. Add 30 and 6, giving 36. Write 6 and carry 3. (3) 2×4=8; add the 3 (carried), equaling 11. Write the 11. NOTE: Always add the "carried" figure to the first product so that it may not be forgotten.

Supplement and complement methods of multiplication.

The supplement of a number is the difference between that number and the next lower MULTIPLE of 10. 2 is the supplement of 12; 8 is the supplement of 108. 25 is the supplement of 1025.

The complement of a number is the difference between that number and the next higher multiple of 10. 4 is the complement of 6; 7 is the complement of 93; 3 is the complement of 997.

To multiply two numbers slightly larger than 100 or 1000 or 10,000: Add the supplement of either number to the other and annex the same number of zeros as occur in the power of ten used. To this add the product of the supplements. 102×104. The supplement of 102 is 2. Add 2 to 104 and annex two zeros and the result is 10600. 2×4=8; add 8 to 10600 and the result, 10608, is the product of 102×104.

To multiply two numbers slightly less than 100, 1000 or 10,000: Subtract the complement of either number from the other number and annex as many zeros as occur in the power of 10 used. To this add the product of the complements. Multiply 93 by 97. The complement of 93 is 7; the complement of 97 is 3. 97−7=90; annexing two zeros, the result is 9000. 3×7=21. Add 21 to 9000 and the result, 9021, is the pr duct of 97 and 93.

DIVISION

Uses.—Division does not occur so frequently in business as either multiplication or addition, but problems involving division are frequently met and the business man and his employees should be able to divide with accuracy and reasonable speed. Furthermore, it is a rather awkward operation on an adding machine and few operators know how to use the machine for division. There are various types of machines upon which a skillful operator can divide with speed and accuracy.

Definitions.—DIVISION, DIVISOR, DIVIDEND, QUOTIENT, REMAINDER. Division is the process of finding how many times one number, called the *divisor*, is contained in another number, called the *dividend*.

The number to be found is called the *quotient*.

When the divisor is not a factor of the quotient; i. e., will not exactly divide the dividend, the part of the dividend remaining is called the *remainder*. Divide 20 by 6. 20 divided by 6 e als 3 with a remainder of 2. In this example, 20 is the dividend, 6 is the divis r, 3 is the quotient, and 2 is the remainder.

The SIGN OF DIVISION is ÷. 24÷6 is read "24 divided by 6". It indicates that the number preceding it is to be divided by the number following it. Division may also be indicated by fraction; e. g., 9/3 means 9 divided by 3.

Short Division.—The following illustrates short division:

```
6)2384616
  397436
```

Short division should be used in all cases where the divisor is 20 or under.

Long Division.—The following illustrates long division:

```
                146
          672)98746
100×672=  67200**
          -----
          31546
 40×672=  26880*
          -----
           4666
  6×672=   4032
          -----
            634
```

*In practice the zeros marked by * are omitted.

Division by Continued Subtraction.—Divide 754 by 142. Division by this method is sometimes required. It has been required on civil service examinations. It is the basis upon which division upon adding machines and the various calculating machines is performed.

```
754

Remainder 44
```

Checking Division.—The following are practical checking methods for division:

(1) Where the divisor and quotient are small numbers, the most practical method is to reverse the operation; i. e., multiply the quotient by the divisor and add the remainder to the product of these two. If the result of these operations is the dividend, the work is probably correct.

(2) Casting out nines. Find the excess of nines in the divisor, dividend, quotient, and remainder. Multiply the excess in the quotient by the excess in the divisor and add the excess in the remainder. The excess of nines in this result should equal the excess of nines in the dividend. See example *A*.

(3) Casting out elevens. Find the excess of elevens in the different parts of the division and proceed as in the proof by casting out nines. See example *B*.

A.

```
          146
672)98746
  672
  ---
  3154
  2688
  ----
   4666
   4032
   ----
    634
```

The excess of nines in the divisor is 6.
The excess of nines in the quotient is 2.
The excess of nines in the dividend is 7.
The excess of nines in the remainder is 4.
6×2 plus 4=16.
The excess of nines in 16 is 7. Since this is the same as the excess of nines in the dividend, the work is probably correct.

B Using the same example as in *A*.

The excess of elevens in the divisor is 1 (11 plus 2 minus 7 plus 6=12). Casting out the elevens in 12 gives an excess of 1.

The excess of elevens in the dividend is 10 (6 minus 4 plus 7 minus 8 plus 9=10).

The excess of elevens in the quotient is 3 (6 minus 4 plus 1=3).

The excess of elevens in the remainder is 7 (4 minus 3 plus 6=7). 3×1 plus 7=10. Since this result is the same as the excess in the dividend, the work is probably correct.

Casting out nines and elevens is a satisfactory method of checking the work when the numbers involved are large. Both the nine and eleven check should be used because one will catch the errors not checked by the other.

Short Methods.—To divide by 10, 100, 1000, etc. point off as many places as there are zeros in the divisor. Divide 47246 by 10. 47246÷10=4724.6. Divide 47246 by 100. 47246÷100=472.46.

To divide by 20, 300, 500, etc. point off as many places as there are zeros in the divisor and then divide by the significant figure.

Divide 3600 by 20. 3600÷20=360.0÷2=180.

Divide 3600 by 600. 3600÷600=36.00÷6=6.

To divide by 25, 50, 125, etc. Since 100 is 4 times 25, it follows that if we divide a number by 100 it will be ¼ of what it would be if divided by 25. Therefore, to divide by 25, first divide by 100 as indicated above and multiply the quotient by 4. For example, divide 32800 by 25. $32800 \div 25 = 328 \times 4 = 1312$.

Since 50 is ½ of 100, to divide by 50, divide by 100 and multiply the quotient by 2. $32800 \div 50 = 328 \times 2 = 656$.

125 is ⅛ of 1000. Therefore, to divide by 125, divide by 1000 and multiply the quotient by 8. $32800 \div 125 = 32.8 \times 8 = 262.4$.

(For further application of aliquot parts to division, see Aliquot Parts.)

AVERAGE

A merchant makes the following daily sales during a week: Monday, $1267.25; Tuesday, $1327.80; Wednesday, $1416.10; Thursday, $1409.65; Friday, $1386.30; Saturday, $1572.50. What are his average daily sales?

Monday	$1267.25
Tuesday	1327.80
Wednesday	1416.10
Thursday	1409.65
Friday	1386.30
Saturday	1572.50
6)8379.60	Total
$1396.60	Average

Rule: To find the average of several amounts, find their sum and divide by the number of amounts.

FACTORS, DIVISORS AND MULTIPLES

Definitions.—An INTEGER is a number of whole units.

The FACTORS of a number are the integers which multiplied together produce the given number. The factors of 12 are 3 and 2 and 2, or 3 and 4, or 2 and 6.

A PRIME NUMBER is a number that is not exactly divisible by any other number.

FACTORING is the process of finding the factors of a number.

Tests of Divisibility of Numbers.—

(1) Even numbers are divisible by 2.

(2) A number is divisible by 3 if the sum of the digits is divisible by 3. 4638 is divisible by 3.

(3) The number is divisible by 4 if the two right hand digits are zeros or express a number which is divisible by 4. 4600 and 4628 are divisible by 4.

(4) If the number ends in 5 or a zero, it is divisible by 5.

(5) Even numbers which are divisible by 3 are divisible by 6. Since 4638 is even and divisible by 3, it is divisible by 6.

(6) There is no practical test for divisibility by 7.

(7) If the number expressed by the last three digits of a number is divisible by 8 or if the last three digits are zeros, the number is divisible by 8. 164000 and 164128 are both divisible by 8.

(8) 7, 11, and 13 will divide 1001 and any of its multiples.

(9) If the sum of the digits of any number is divisible by 9, the number is divisible by 9; e. g., 1386 or 3168.

(10) If the right hand digit of any number is zero, the number is divisible by 10.

(11) If the two right hand digits are zeros or express a number which is divisible by 25, the number is divisible by 25. 14875 is divisible by 25.

(12) If the difference between the sums of the digits of the even and odd orders is divisible by 11, the number is divisible by 11. In the number 6324846, the sum of the digits of the even order is 22; the sum of the digits of the odd order is 11; and the difference, 11, is divisible by 11. Therefore, the number is divisible by 11.

(13) If the three right hand digits are zeros or represent a number divisible by 125, the number is divisible by 125. 78457250 is divisible by 125.

DIVISORS

Definitions.—A COMMON DIVISOR or FACTOR of two or more numbers is a factor of each of the numbers.

THE GREATEST COMMON DIVISOR is the greatest factor that is common to two or more numbers.

Finding the Greatest Common Divisor (G. C. D.)—To find the Greatest Common Divisor of two or more numbers, separate the numbers into their prime factors and find the product of the prime factors common to the numbers.

First Method:

Find the G. C. D. of 27−36−63

3)27−36−63

3)9−12−21

3− 4− 7 G. C. D. $= 3 \times 3 = 9$

Second Method: The G. C. D. of two numbers is their difference or a factor of their difference. Find the G. C. D. of 84 and 124. The difference between these numbers is 40 but this is not a factor of either of them. The factors of 40 are $2 \times 2 \times 2 \times 5$. Inspection shows that the numbers are not divisible, 5 nor 10 nor 8, but are divisible by 4. 4 is therefore the G. C. D.

The G. C. D. of three or more numbers is the smallest difference or a factor of this difference. Find the G. C. D. of 60, 96 and 120. The smallest difference is 24. The factors of 24 are $2 \times 2 \times 2 \times 3$. Inspection shows that they are not divisible by 24, but are divisible by 2, 4, 8 and 12. Therefore, 12 is the G. C. D.

The practical application of G. C. D. is in the reduction of common fractions to lower terms.

LEAST COMMON MULTIPLE

Definitions.—A MULTIPLE of a given number is a number that will exactly contain the given number.

A number that will exactly contain each of two or more numbers is called a COMMON MULTIPLE.

The smallest number that will exactly contain each of two or more numbers is called the LEAST COMMON MULTIPLE (L. C. M.)

The practical application of L. C. M. is found in addition and subtraction of common fractions.

To find the Least Common Multiple of two or more numbers:

First Method: Separate each number into its prime factors. Find the product of these factors using each factor the greatest number of times it occurs in any one of the given numbers.

Example: Find the L. C. M. of 24−36−21.

$24 = 2 \times 2 \times 2 \times 3$.

$36 = 2 \times 2 \times 3 \times 3$.

$21 = 3 \times 7$.

$2 \times 2 \times 2 \times 3 \times 3 \times 7 = 504$.

Second Method: Set the numbers down in a line and divide by any factor common to any two or more of the numbers. Bring down the quotients and the indivisible numbers on the next line. Repeat the operation until the quotients are prime to each other. The product of the divisors and last quotients is the L. C. M.

Example: Find the L. C. M. of 24−36−21.

A		*B*
3)24−36−21		3)24−36−21
2) 8−12− 7	or	4) 8−12− 7
2) 4− 6− 7		2− 3− 7
2− 3− 7		

C

12)24−36−21

or 3) 2− 3−21

2− 1− 7

A. $3 \times 2 \times 2 \times 2 \times 3 \times 7 = 504$.

B. $3 \times 4 \times 2 \times 3 \times 7 = 504$.

C. $12 \times 3 \times 2 \times 7 = 504$.

Third Method: Set the numbers down in a line. Use any one of them as a divisor and bring down the quotients, or the result of extracting common factors, or, in case a number is indivisible either by the divisor or a common factor, bring down that number.

Example: Find the L. C. M. of 24, 36 and 21.

24)24−36−21

1− 3− 7 $7 \times 24 \times 3 = 504$.

CANCELLATION

It sometimes happens that the product of several numbers is to be divided by the product of several other numbers. A problem of this kind can be quickly and simply solved by cancellation method.

Divide the product of $8 \times 6 \times 10 \times 15$ by the product of $3 \times 4 \times 9 \times 2$.

$$\frac{\cancel{8}^{2} \times \cancel{6}^{2} \times \cancel{10}^{5} \times \cancel{15}^{5}}{\cancel{3} \times \cancel{4} \times \cancel{9}^{3} \times \cancel{2}} = 100 = 33\ 1/3$$

Place the elements of the dividend above the line; the divisor below the line.

Process: Divide 3 and 6 by the common factor 3 and place the 2 above the 6. It is not necessary to write the 1 below the 3. Cancel the 3 and 6.

Divide 8 and 4 by the common factor, 4, and place the 2 above the 8. Cancel the 8 and 4.

Divide the 10 and 2 by the common factor, 2, and place the 5 above the 10. Cancel 10 and 2.

Divide 9 and 15 by the common factor, 3, and place the 5 above the 15 and the 3 below the 9. Cancel the 9 and 15.

As there is no factor common to numbers on opposite sides of the line, perform the indicated multiplication and division.

COMMON FRACTIONS

Use.—Quantities, prices, dimensions, relations, etc., in business are frequently stated in fractions. For this reason, anyone who wishes to be in a position to handle the arithmetic of business must understand fractions.

Definitions.—A FRACTION is one or more equal parts of a unit. If a pie be divided into five equal parts, each of these parts is called a fifth. If a person takes two of these equal parts, he will have two-fifths of the pie. The whole pie, or unit, contains five fifths.

A FRACTION is also defined as an indicated division.

A COMMON FRACTION is one usually expressed in the following form: ½.

The DENOMINATOR of a fraction is the number below the line and is the number which indicates into how many equal parts the unit is divided. In the fraction 2/5, the 5 shows that the unit has been divided into five equal parts.

The NUMERATOR of a fraction is the number written above the line and is the number which shows how many of these parts of the unit have been taken. In the fraction 2/5, the 2 is the numerator and it shows that two of the five equal parts have been taken.

The numerator and denominator of the fraction are called the TERMS of the fraction.

A PROPER FRACTION is one in which the numerator is smaller than the denominator; e. g., 2/3.

An IMPROPER FRACTION is one in which the numerator is as large as or larger than the denominator; e. g., 5/5; 5/2.

A MIXED NUMBER is a number which consists of a whole number and a fraction; e. g., 1½.

A COMPLEX FRACTION is one in which the numerator or denominator, or both, is a mixed number.

A fraction in which the numerator and denominator contain common factors may be reduced to its LOWEST TERMS by dividing both numerator and denominator by the common factor. $\frac{8}{16} = \frac{1}{2}$

A fraction may be raised to HIGHER TERMS by multiplying both numerator and denominator by the same number:

$$\frac{4\times2}{4\times3} = \frac{8}{12}$$

Reducing to lowest terms or raising to higher terms does not change the value of the fraction.

An improper fraction may be changed to a mixed number by performing the indicated division:

$12/3 = 4$ $\quad$ $7/2 = 3\frac{1}{2}$

A mixed number may be changed to an improper fraction by multiplying the whole number by the denominator of the fraction and adding the numerator to the product. The result is the numerator of the improper fraction. The denominator is the denominator of the fractional part of the mixed number. Change 2½ to an improper fraction. 2×2 plus 1=5. 5/2 is the improper fraction.

Fractions may be reduced to a common denominator by finding the common multiple of the denominators. When the common denominator is found, multiply both terms of the fraction by the number necessary to raise the denominator to the common denominator. Reduce 3/4 and 2/5 to a common denominator. The L. C. M. of 4 and 5 is 20. Multiply both terms of 3/4 by 5 and both terms of 2/5 by 4. The result is 3/4 equals 15/20 and 2/5 equals 8/20.

Addition of Fractions.—To add fractions:

(1) Reduce the fractions to the least common denominator.

(2) Add the numerators to form the numerator of the sum.

(3) Write the common denominator as the denominator of the sum.

(4) Reduce the result to its simplest form.

(5) If the fractions are mixed numbers, add the fractions and reduce to simplest form, and then add the sum of the whole numbers and the sum of the fractions.

(6) *Example*: Add 2/3, 4/5 and 3/4.

2/3—40
4/5—48
3/4—45

$$\frac{133}{60} = 2\frac{13}{60}$$

Add 5 1/2 and 6 2/3

5 1/2—3
6 2/3—4

11 $\quad$ 7/6=1 1/6
1 1/6

12 1/6

(7) To add two fractions having the same numerator: Find the product of the denominators for the denominator of the sum; multiply the sum of the denominators by the common numerator and this is the numerator of the sum. *Example*: Add 3/5 and 3/7. The numerator of the sum is 3×(5+7)=36. The denominator of the sum is 5×7=35. The sum is 36/35=1 1/35.

Subtraction of Fractions.—To subtract fractions:

(1) Reduce the fractions to the least common denominator.

(2) If the minuend is larger than the subtrahend, subtract the numerators and write the result as the numerator of the remainder and the common denominator as the denominator.

(3) If the minuend is a mixed number and the fractional part is smaller than that of the subtrahend, borrow one unit from the whole number of the minuend and add to the fractional part, making it an improper fraction. Subtract as in (2); subtract the whole numbers, remembering to take account of the unit borrowed, and add the two remainders.

(4) *Example*: Subtract 3/4 from 5/6.

5/6—10
3/4— 9

1

12

Subtract 1 5/6 from 3 3/4. 3 3/4−1 5/6=1 11/12.

3 3/4—21
1 5/6—10

1 11/12

Multiplication of Fractions.—To multiply fractions:

(1) Multiplication may be indicated by "×" or "of".

(2) Multiply the numerators to find the numerator of the product.

(3) Multiply the denominators to find the denominator of the product.

(4) Reduce to simplest form.

(5) Mixed numbers may be reduced to improper fractions and multiplied as above but see (8) and (9).

(6) The work of multiplication of fractions may be simplified by cancellation.

$$\frac{1}{\cancel{2}}\times\frac{\cancel{2}^{2}}{5} = \frac{2}{5}$$

(7) Where the multiplier is a whole number, multiply the numerator of the fraction by the whole number.

3×1/2=3/2=1 1/2

(8) Particularly where the whole numbers are large, the multiplication of a whole number by a mixed number may be simplified as follows:

(*a*) Multiply the whole number by the numerator of the fraction.

(*b*) Divide the above result by the denominator of the fraction.

(*c*) Proceed with the multiplication by the whole number of the mixed number and add the results.

Multiply 24 2/5×14.

24 2/5
14

5)28 $\quad$ =2×14
53/5=2/5×14
96
24

341 3/5

(9) Particularly when the integral parts of mixed numbers are large, the work may be simplified as follows:

(*a*) Multiply the fractional parts of the mixed numbers.

(*b*) Multiply the integral part of the multiplicand by the fractional part of the multiplier.

(*c*) Multiply the integral part of the multiplier by the fractional part of the multiplicand.

(*d*) Multiply the integral parts of the two numbers.

(*e*) Add the results.

(*d*) *Example*: 248 1/2×15 1/4:

1/2×1/4= 1/8
1/4×248= 62
1/2×15 = 7 1/2
15×248=3720

3789 5/8

(10) To square a mixed number ending in ½. Square the fraction. Add 1 to the whole number of the multiplicand and multiply by the whole number of the multiplier. 7½×7½=56¼. (7 plus 1)×7=56; ½×½=¼.

(11) To multiply two mixed numbers ending in ½.

(*a*) If the sum of the integers is even, square the fraction, and to the product of the integers add one-half their sum.

(*b*) If the sum of the integers is odd, write ¾ as the fractional part of the product. To this annex the product of the integers plus the one-half of their sum, dropping the fractional part of the sum.

Division of Fractions.—

(1) To divide a number by a fraction, invert the terms of the divisor and multiply. 3/4÷2=3/4×1/2=3/8.

(2) If the divisor is a mixed number or fraction and the dividend is a mixed number or fraction, the mixed numbers should be reduced to improper fractions.

(3) The work may be simplified in (2) by multiplying both numbers by the common denominator of the fractional parts.

Example: 48 3/4÷7 1/3. Reduce the mixed numbers to improper fractions having a common denominator. 48 3/4=585/12; 7 1/3=88/12. Since 585/12÷88/12=585/12×12/88=585/88, the common denominator may be disregarded and the numerator of the dividend divided by the numerator of the divisor. 88)585

6 57/88

(4) If the divisor is a whole number and the dividend is a mixed number, divide each part by the divisor and add the quotients.

24 1/2÷3=8 1/6
24÷3=8; 1/2÷3=1/6

(5) The work on (4) may also be performed as described in (3):

24 1/2÷3=8 1/6
24 1/2=49/2; 3=6/2; 49÷6=8 1/6

DECIMAL FRACTIONS

Use. In Business.—Fractions probably occur in the decimal form in business computations more frequently than in the

common form. As any common fraction can be changed to decimal form and is more easily handled in that form, every business man should acquire facility in handling them. When calculations involving fractions are performed on the various types of calculating machines, the fraction is nearly always reduced to the decimal form.

Definition.—A decimal fraction is one whose denominator is some power of ten. The denominator is indicated by the number of the places to the right of a period, called the decimal point, occupied by right-hand figure of significance. Thus, the indicated denominator of .2 is 10; the indicated denominator of .125 is 1000. The reading of the integral and decimal orders is indicated in the following table:

Integers	Order	Decimals
Units	1	Tenths
Tens	2	Hundredths
Hundreds	3	Thousandths
Thousands	4	Ten-thousandths
Ten-thousands	5	Hundred-thousandths
Hundred-thousands	6	Millionths
Millions	7	Ten-millionths
Ten-millions	8	Hundred-millionths
	etc.	

To Add Decimals.—Arrange the amounts to be added in such a way that the decimal points fall in a vertical line. Proceed as in ordinary addition. Place the decimal point in the sum directly below in a line with the decimal points in the numbers added. Add 28.5, 125.03, 1.5, 78.105.

```
  28.5
 125.03
   1.5
 78.105
 ------
233.135
```

To Subtract Decimals.—Arrange the amounts in such a way that the decimal points fall in a vertical line. Proceed as in ordinary subtraction of whole numbers. Place the decimal in the remainder directly below and in a line with the decimal points in the subtrahend and minuend.

Subtract .1463 from 2.46.

Solution:

```
 2.46
 .1463
------
2.3137
```

Multiplication of Decimals.—Multiply as with whole numbers. The number of decimal places in the product is the sum of the number of decimal places in both the multiplier and multiplicand. $416\times.25=104.00$. $.4016\times.025=.01004$.

Division of Decimals.—Divide as with whole numbers.

Rules for pointing off in the quotient:

Rule 1. The number of decimal places in the quotient is equal to the number of places in the dividend minus the number of places in the divisor. If there are more places in the divisor than in the quotient, add enough zeros to make the number of places equal to the number of places in the divisor. Example *A* and *A*2.

Rule 2. (*a*) If the divisor is a whole number, insert the decimal point in the quotient when it is reached in the dividend. Example *B*.

(*b*) If the divisor is not an integer, multiply both divisor and dividend by the least power of ten that will make the divisor a whole number and proceed as in (*a*). Example *B*2.

If there is a remainder in the division of decimals, zeros may be added and the division carried to as many places in the quotient as is desired.

When the quotient is required to be to the *nearest* tenth, hundredth, etc., carry the division one place further than the order required and then adjust the quotient.

Example A: Divide 3.9905 by 3.47. $39905\div347=115$.

4 places in the dividend minus 2 places in the divisor equals 2 places in the quotient. Therefore $3.9905\div3.47=1.15$.

*Example A*2: Divide 3990.5 by 3.47. Since there are two places in the divisor and but one in the dividend, add a zero to the dividend. $399050\div347=1150$. 2 places − 2 places = 0 places. Therefore $3990.50\div3.47=1150$.

Example B: Divide 399.05 by 347:

```
   1.15
347)399.05
   347
   ---
   520
   347
   ---
  1735
  1735
  ----
```

*Example B*2: Divide 399.05 by 34.7. Multiplying both dividend and divisor by 10 eliminates the decimal in the divisor. $3990.5\div347=11.5$

```
    11.5
347)3990.5
```

Division by 10, 100, 1000, etc. To divide by 10 or a power of ten, move the decimal point in the dividend to the left as many places as there are zeros in the divisor. It may be necessary to place zeros between the decimal point and the first left figure of significance in the quotient; thus, $24\div1000=.024$. This same principle may be extended to 20, 200, 3000, 5000, etc., by moving the decimal point and dividing by 2, 3, or 5 as the case may be.

Division by 25, 50, 125, etc. To divide by 25, divide by 100 and multiply the result by 4.

To divide by 50, divide by 100 and multiply the result by 2.

To divide by 125, divide by 1000 and multiply by 8.

For other applications of aliquot parts to division, see Aliquot Parts.

Changing Decimal Fractions to Equivalent Common Fractions.—To change a decimal fraction to its equivalent common fraction, omit the decimal point and write the indicated denominator. Reduce to lowest terms. *Example*:

$$.125=\frac{125}{1000}=\frac{1}{8} \qquad .16=\frac{16}{100}=\frac{4}{25} \qquad .2=\frac{2}{10}=\frac{1}{5}$$

Changing Common Fractions to Equivalent Decimal Fractions.—To change a common fraction to a decimal fraction, divide the numerator by the denominator, carrying the division to as many decimal places as desired. It is usually not necessary to carry the division further than four or five places.

Example:

```
7/16 = 16)7.0000        7/8 = 8)7.000
          64                    .875
          60
          48
         120
         112
          80
          80
```

Reciprocals.—The reciprocal of any number is unity divided by that number. ¼ is the reciprocal of 4. Where several numbers are to be divided by another number, as in pro-rating, it is frequently much easier to find the reciprocal decimal and multiply each number by it.

ALIQUOT PARTS

Definition.—An aliquot part of a number is that part which is contained an integral number of times in the given number. *Examples*: 2½ is an aliquot part of 10, 100, and 1000 because it is contained in each of these an even number of times. 25 is an aliquot part of 100 and 1000. 125 is an aliquot part of 1000.

Use.—The use of aliquot parts has been mentioned in the methods of multiplication and division. Through the use of the methods, which will now be further explained, the work of multiplication and division by certain numbers is made much easier and the results can be obtained very much more quickly. Since prices are very frequently fixed at aliquot parts of one dollar, the multiplication in billing and similar work can be very much simplified and speed can be developed by gaining facility in handling these short cuts.

Table.—The following is a general table of the more common aliquot parts. It will be noticed that only the simplest forms of fractions are given. The equivalents which are very seldom used have been omitted. Aliquot parts less frequently used have been marked with an asterisk (*).

Numbers	1/2	1/3	2/3	1/4	3/4	1/5	2/5
10	5	3 1/3	6 2/3	2 1/2	7 1/2	2	4
100	50	33 1/3	66 2/3	25	75	20	40
1000	500	333 1/3	666 2/3	250	750	200	400

Numbers	3/5	4/5	1/6	5/6	1/7*	1/8	3/8
10	6	8	1 2/3	8 1/3		1 1/4	3 3/4
100	60	80	16 2/3	83 1/3	14 2/7*	12 1/2	37 1/2
1000	600	800	166 2/3	833 1/3		125	375

Numbers	5/8	7/8	1/9*	1/11*	1/12	5/12	7/12
10	6 1/4	8 3/4					
100	62 1/2	87 1/2	11 1/9*	9 1/11	8 1/3	41 2/3	58 1/3
1000	625	875			83 1/3		

Numbers	11/12	1/15	1/16	1/10	1/20	1/30	1/40	1/50
100	91 2/3	6 2/3	6 1/4	10	5	3 1/3	2 1/2	2
1000			62 1/2	100	50	33 1/3	25	20

Multiplying by aliquot parts of 10:

$416\times2\ 1/2$. Since 2 1/2 is 1/4 of 10, $(416\times10)\div4=1040$.

$920\times7\ 1/2$. Since 7 1/2 is 3/4 of 10, $(920\times10\times3)\div4=6900$.

OR $(920\div4)\times10\times3=6900$.

Multiplying by aliquot parts of 100:

$32\times6\ 1/4$. Since 6 1/4 is 1/16 of 100, $(32\times100)\div16=200$.

25×288. Since 25 is 1/4 of 100, $(288\times100)\div4=7200$.

$640\times87\ 1/2$. Since 87 1/2 is 7/8 of 100, $(640\times100\times7)\div8=56000$.

OR $(640\div8)\times100\times7=56000$.

Multiplying by aliquot parts of 1000:
1280×125. Since 125 is 1/8 of 1000 (1280×1000)÷8=160000.
OR (1280÷8)×1000=160000.
1680×625. Since 625 is 5/8 of 1000, (1680×1000×5)÷8=1050000.
OR (1680÷8)×1000×5=1050000.
Dividing by aliquot parts of 10:
Divide 16 by 1 1/4. Since 1 1/4 is 1/8 of 10, the quotient of 16÷10 will be 1/8 of the quotient of 16÷1 1/4. Therefore, 16÷1 1/4=(16÷10)×8=12.8.
Dividing by aliquot parts of 100:
1720÷33 1/3=(1720÷100)×3=51.6.
1284÷37 1/2=[(1284÷100)÷3]×8=34.24.

Interchanging multiplier and multiplicand sometimes makes possible the application of the short methods of aliquot parts: .32×7500=.75×3200=2400.

DENOMINATE NUMBERS

Uses.—Civilized man makes constant use of measures and measurement. He buys and sells by units of measure; he indicates size and magnitude of quantity by measure; he compares quantities by measure. For example, he buys butter by the pound; he orders a bin to contain fifty bushels of wheat; and he finds that Henry's farm contains sixty-five acres, while Brown's farm contains sixty-two acres.

A Denominate Number is a concrete number whose unit of measure is established by law or custom.

A Simple Denominate Number is one that is expressed by the units of one denomination; e. g., five pounds, or three gallons.

A Compound Denominate Number is one that is expressed by the units of two or more denominations that are related to one another; e. g., five pounds six ounces, or three gallons one pint.

Tables.—The following tables show the most commonly used measures:

United States Money is the legal currency of the United States. It consists of gold, silver, nickel, and copper coins; treasury, and Federal Reserve Bank notes.

Table of United States Money

10 mills	= 1 cent	*c. ct. ¢*
10 cents	= 1 dime	*d.*
10 dimes	= 1 dollar	*$.*
10 dollars	= 1 eagle	*E.*

The mill is not coined; it is used only as the decimal part of a cent.

The following denominations are now coined
Gold.....$20, $10, $5.
Silver.....$1, 50c, 25c and 10c pieces.
Nickel.....5c piece.
Bronze.....1c piece.

WEIGHTS AND MEASURES.—Practically all the commerce of the world is conducted through the medium of two systems of weights and measures, namely, the English system and the metric system. Practicalily all the engineering work done in the world with the exception of that done in Japan is based upon one or the other of these systems. In the United States and in Great Britain and its possessions both systems are legal and in use, the English being used in all ordinary commercial transactions and the metric in all scientific work and to a lesser extent in technical work.

The English System.—The customary system of weights and measures in use in the United States is the same as the system in everyday use in Great Britain, with some important differences in some of the units which must be noted. For all practical purposes the units of length and mass are identical in value, although the fundamental standards of the two countries are quite different. In Great Britain the standaid yard is a bronze bar in the custody of the board of trade and preserved in the standards office, Westminster. Its legal value in terms of the international meter is, one yard equals $\frac{36}{39.370113}$ meters.

In the United States the meter is the fundamental standard and the yard is defined as $\frac{3600}{3937}$ meters. The difference in the value of the two yards in terms of the meter only amounts to a little more than one part in 400,000, which is about the difference found in comparing the imperial yard with its authentic copies at different periods. It is therefore doubtful whether there is a real difference between the length of the English bronze yard and United States yard derived from the meter.

A similar condition exists with respect to the avoirdupois pounds; in England a certain p'atinum cylinder deposited in the standards office is regarded as the standard pound, while in the United States the pound is defined as 453.5924277 grams, of which the international kilogram contains 1,000. This is the same as the legal value in Great Britain, so that the only difference in the two pounds is one of standards.

On the other hand the capacity measures of the two countries are quite different. The United States ga'lon of 231 cubic inches and the Winchester bushel of 2150.42 cubic inches have not been legal measures in Great Britain since 1825, having been superseded by the present imperial gallon, which is defined as the volume of 10 pounds of pure water at 62 degrees Fahrenheit, weighed against brass weights in air at the same temperature as the water, and with the barometer at 30 inches. The imperial bushel is defined as the volume of 80 pounds of water weighed under the same conditions as the gallon. The bushel of Great Britain is, therefore, exactly equal to 8 gallons.

The volume of the imperial gallon, according to the most reliable data available at this time, is 277.420 cubic inches and the bushel 2219.36 cubic inches, the first being larger than the United States gallon by approximately 20 per cent, and the latter larger than the United States bushel by 3.2 per cent.

The methods of subdividing and multiplying the yard, pound, gallon, and bushel in the two countries are substantially the same.

Standard Weights and Measures of United States

AVOIRDUPOIS WEIGHT

Dram	dr.	=27 1/2 grains (27.34375).
Ounce	oz.	=16 drams, 437.5 grains.
Pound	lb.	=16oz.,256dr.,7,000grains.
Legal stone	st.	=14 lbs.
Quarter (Eng.)	qr.	=28 lbs.
Quarter (Can.)	qr.	=25 lbs.
Cental or quintal	cent.	=100 lbs.
Hundredwgt.(Eng.),cwt.		=4 qrs., 112 lbs.
Hundredwgt.(Can.),cwt.		=4 qrs., 100 lbs.
Ton (Eng.)	T.	=20 cwt., 2,240 lbs.
Ton (Can.)	T.	=20 cwt., 2,000 lbs.

Ton of Coal.—The United States ton is legally defined in some states as 2,000 pounds and in other states as 2,240 pounds. In Arizona, Colorado, Connecticut, Idaho, Indiana, Kansas, Kentucky, Louisiana, Massachusetts, Montana, Nebraska, New Jersey (net ton), New York, Ohio, Rhode Island (net ton), Vermont, Washington, and Wisconsin, it is fixed at 2,000 pounds, and in the District of Columbia, Pennsylvania, New Jersey (gross ton), Rhode Island (gross ton), it is fixed at 2,240 pounds. For tariff purposes Congress has fixed the ton of coal at 2,240 pounds.

TROY WEIGHT

Carat		=3.17 grains.
Pennyweight	dwt.	=24 grains.
Ounce	oz.	=20 dwts., 480 grains.
Pound	lb.	=12 oz.,240dwts.,5,760grs.
Hundredweight	cwt.	=100 lbs.

Troy is the weight used by goldsmiths and jewelers. The grains troy, apothecaries', and avoirdupois are equal, and the same in England, France, the United States, Holland, and in most other countries.

The oz. troy and apothecaries' =1.09714 oz. avoirdupois; but the lb. troy and lb. apothecaries' =only 0.82286 lb. avoirdupois, while 175 lbs. troy and apothecaries' =144 lbs. avoirdupois.

APOTHECARIES' WEIGHT

Scruple	℈ =20 grains	= 20 grains.
Dram	ʒ = 3 scruples	= 60 grains.
Ounce	℥ = 8 drams	= 480 grains.
Pound	lb =12 ounces	=5,760 grains.

APOTHECARIES' FLUID MEASURE

		Marked
60 minims ♏ (drops)..	=1 fluid dram	f ʒ
8 drams	=1 ounce	f ℥
16 ounces	=1 pint	O
8 pints	=1 gallon	C., or Cong.

1 dram	=1 teaspoonful.
2 drams	=1 dessertspoonful.
4 drams	=1 tablespoonful.
2 ounces	=1 wineglassful.
3 ounces	=1 teacupful.

LIQUID MEASURE

		Cubic Inches
4 gills	1 pint (O)	= 28.875
2 pints	1 quart (qt.)	= 57.75
4 quarts	1 gallon (gal.)	=231.0
63 gallons	1 hogshead (hhd.).	
2 hogsheads	1 pipe or butt.	
2 pipes	1 tun.	

DRY MEASURE

		Cubic Inches
2 pints	1 quart (qt.)	= 67.20
4 quarts	1 gallon (gal.)	= 268.80
2 gallons, or 8 quarts	1 peck	= 537.60
4 pecks	1 struck bushel	=2150.42

HOUSEHOLD MEASURES

120 drops water	=1 teaspoon.
60 drops thick fluid	=1 teaspoon.
2 teaspoons	=1 dessertspoon.
3 teaspoons	=1 tablespoon.
16 tablespoons	=1 cup.
1 cup	= ½pt.
1 cup water	= ½lb.
4 tablespoons flour	=1 oz.
2 tablespoons butter	=1 oz.
3 teaspoons soda	= ½oz.
4 teaspoons baking powder	= ½oz.
2 cups granulated sugar	=1 lb.
2½ cups confectioners' sugar	=1 lb.
2½ cups wheat flour	=1 lb.
3½ cups whole wheat flour	=1 lb.
2½ cups buckwheat flour	=1 lb.
5½ cups coffee	=1 lb.
6½ cups tea	=1 lb.
2 cups rice	=1 lb.
2 cups lard	=1 lb.
2 cups butter	=1 lb.
2 cups graham flour	=1 lb.
2 cups rye flour	=1 lb.
2 cups corn meal	=1 lb.
2 cups rolled oats	=1 lb.
2 cups powdered sugar	=1 lb.
2 cups brown sugar	=1 lb.
2 cups raisins	=1 lb.
2 cups currants	=1 lb.
2 cups bread crumbs	=1 lb.
9 eggs	=1 lb.

CUBIC OR SOLID MEASURE

Cubic foot	=1,728 cubic inches.
Cubic yard	=27 cubic feet, 21,033 bushels.
Cord of wood	=128 cubic feet.
Shipping ton	=40 cubic feet merchandise.
Shipping ton	=42 cubic feet of timber.
Ton of displacement of a ship	=35 cubic feet.

LINEAR MEASURE

3 barleycorns, or 12 lines, or 72 points, or 1,000 mils (mi.).	1 inch (in.).
3 inches	1 palm.
4 inches	1 hand.
9 inches	1 span.
12 inches	1 foot (ft.).
18 inches	1 cubic.
3 feet	1 yard (yd.).
2½ feet	1 military pace.
5 feet	1 geometrical pace.
2 yards	1 fathom.
5½ yards	1 rod, pole, or perch.
66 feet, or 4 rods	1 Gunter's chain.
40 poles, or 220 yards	1 furlong (fur.).
8 furlongs, or 1,760 yards, or 5,280 feet	1 mile.
3 miles	1 league.

The hand is used to measure horses' height. The military pace is the length of the ordinary step of a man. One thousand geometrical paces were reckoned to a mile.

LAND MEASURE (LINEAR)

7.92	inches	1 link.
100	links, or	1 chain (ch.).
66	feet, or	
22	yards, or	
4	poles	
10	chains	1 furlong (fur.).
80	chains, or	1 mile.
8	furlongs	

LAND MEASURE (SQUARE)

144 square inches	1 square foot (sq. ft.).
9 square feet	1 square yard (sq.yd.).
30¼ square yards	1 sq.pole, rod,or perch.
16 square poles	1 square chain (sq.ch.).
40 square poles, or	1 square rood.
1,210 square yards	
4 square roods, or	
10 square chains, or	
160 square poles, or	1 acre.
4,840 square yards, or	
43,560 square feet	
640 acres, or	1 square mile.
3,097,600 square yards	
30 acres	1 yard of land.
100 acres	1 hide of land.
40 hides	1 barony.

GEOGRAPHICAL AND NAUTICAL MEASURE

6086.44	feet, or	=1 nautical mile.
1000	fathoms, or	
10	cables, or	
1.1528	statute miles	
1	nautical mile per hr.	=1 knot.
60	nautical miles, or	=1 degree.
67.168	statute miles	
360	degrees	=1 circumference of the earth at the equator.
1	league	=3 nautical miles.
1	cable's length	=120 fathoms.

TIME

The unit of time measurement is the same among all nations. Practically it is $\frac{1}{86400}$ of the mean solar day, but really it is a perfectly arbitrary unit, as the length of the mean solar day is not constant for any two periods of time. There is no constant natural unit of time.

1 minute	=60 seconds.
1 hour	=60 minutes, 3,600 seconds.
1 day	=24 hours, 1,440 minutes, 86,400 seconds.
1 sidereal day	=86,164.1 seconds.
1 sidereal month	=27.321661 mean solar days (average).
1 lunar month	=29.530589 mean solar days (average).
1 anomalistic month	=27.544600 mean solar days (average).
1 tropical month	=27.321582 mean solar days (average).
1 nodical month	=27.212222 mean solar days (average).
Mean solar year	=365 d. 5 h. 48 m. 46.045 s. with annual variation of 0.00539.

The change in the length of the mean sidereal day, *i. e.*, of the time of the earth's rotation upon its axis, amounts to 0.01252 s. in 2,400 mean solar years.

ANGULAR MEASURE

There is perfect unanimity as to the standard angle (i. e., the right angle) and practical unanimity as to its subdivision, for the subdivision into grades, etc., once favored by the French, is now abandoned.

1 minute of angle or arc =60 seconds.
1 degree of angle or arc =60 minutes.
90 degrees of angle or arc =1 right angle or ¼ of circumference.

Radian of angle or arc	=arc same length as radius.
Radian of angle or arc	=57.295779513082°.
Length of arc of 1°	= 0.017453292520.
Length of arc of 1′	= 0.015707963268.
Length of arc of 1″	= 0.000290888209.

Time on Shipboard.—The twenty-four hours are divided on board ship into seven parts, and the crew is divided into two parts or watches, designated *port* and *starboard watches*. Each watch is on duty four hours, except from 4 to 8 p.m., which time is divided into two watches of two hours each, called *dog watches*, by means of which the watches are changed every day, and each watch gets a term of eight hours' rest at night. *First watch*, 8 p.m. to midnight; *middle watch*, midnight to 4 a.m.; *morning watch*, 4 to 8 a.m.; *forenoon watch*, 8 a.m. to noon; *afternoon watch*, noon to 4 p.m.; *first dog watch*, 4 to 6 p.m.; *second dog watch*, 6 to 8 p.m. The bell is struck every half-hour to indicate the time, as follows:

1 bell	12.30 a.m.	1 bell	12.30 p.m.
2 bells	1.00 a.m.	2 bells	1.00 p.m.
3 bells	1.30 a.m.	3 bells	1.30 p.m.
4 bells	2.00 a.m.	4 bells	2.00 p.m.
5 bells	2.30 a.m.	5 bells	2.30 p.m.
6 bells	3.00 a.m.	6 bells	3.00 p.m.
7 bells	3.30 a.m.	7 bells	3.30 p.m.
8 bells	4.00 a.m.	8 bells	4.00 p.m.
1 bell	4.30 a.m.	1 bell	4.30 p.m.
2 bells	5.00 a.m.	2 bells	5.00 p.m.
3 bells	5.30 a.m.	3 bells	5.30 p.m.
4 bells	6.00 a.m.	4 bells	6.00 p.m.
5 bells	6.30 a.m.	1 bell	6.30 p.m.
6 bells	7.00 a.m.	2 bells	7.00 p.m.
7 bells	7.30 a.m.	3 bells	7.30 p.m.
8 bells	8.00 a.m.	4 bells	8.00 p.m.
1 bell	8.30 a.m.	1 bell	8.30 p.m.
2 bells	9.00 a.m.	2 bells	9.00 p.m.
3 bells	9.30 a.m.	3 bells	9.30 p.m.
4 bells	10.00 a.m.	4 bells	10.00 p.m.
5 bells	10.30 a.m.	5 bells	10.30 p.m.
6 bells	11.00 a.m.	6 bells	11.00 p.m.
7 bells	11.30 a.m.	7 bells	11.30 p.m.
8 bells	12.00 n'n.	8 bells	12.00 ngt.

Board and Timber Measure.—A board one foot square and one inch thick is the unit of board measure, the number of feet in a board being determined by the number of times its volume equals that of the unit: Thus a board 2 inches thick, 1½ feet wide and 10 feet long contains 30 feet. A board of the same length and width ½ inch thick would contain 7½ board feet.

The Doyle Rule.—Known in some sections as the Connecticut River Rule, the St. Croix Rule, the Thurber Rule, the Moore & Beeman Rule, and the Scribner Rule—is used throughout the entire country and is more generally employed than any other. It is constructed by the following formula: Deduct 4 inches from the diameter of the log as an allowance for slab; square one-quarter of the remainder and multiply the result by the length of the log in feet. It is the usual custom to measure the diameter inside the bark at the small end. One cord of wood is 128 cubic feet.

In metric countries all wood is measured in cubic meters.

Water Measure.—*The Miner's Inch* is usually defined as the quantity of water that will pass through an orifice 1 square inch in cross section under a given head. The head has been fixed in various localities at from 4 to 6½ inches to the center of the orifice. In states where the miner's inch is defined by statute it varies from $\frac{1}{40}$ to $\frac{1}{50}$ of a cubic foot per second. The miner's inch is rapidly becoming obsolete, its place being taken by the cubic foot per second or the gallon per second. The United States reclamation service uses the cubic foot per second.

Visibility Distance at Sea.—Table of elevations of objects above sea level, with their corresponding distances of visibility.

Height in Feet	Distance in Nautical Miles	Height in Feet	Distance in Nautical Miles
5	2.555	110	11.986
10	3.614	120	12.519
15	4.426	130	13.030
20	5.111	140	13.522
25	5.714	150	13.997
30	6.260	200	16.162
35	6.761	250	18.070
40	7.228	300	19.795
45	7.666	350	21.381
50	8.081	400	22.857
55	8.476	450	24.244
60	8.852	500	25.555
65	9.214	550	26.802
70	9.562	600	27.994
75	9.897	650	29.137
80	10.222	700	30.237
85	10.536	800	32.325
90	10.842	900	34.286
95	11.139	1000	36.140
100	11.428		

Metric System.—The unit of length in the metric system is the *meter*, a length originally planned to be equal to the one ten-millionth of the distance between the equator and the pole, measured along a terrestrial meridian. A platinum bar of this supposed length was constructed and deposited in the archives of the French republic in 1799. At the same time a platinum weight was constructed which was made equal to the mass of a cube of pure water at 4 degrees centigrade, the sides of the cube being one-tenth the length of the meter. This weight, which is equal to one thousand units of mass in the metric system, is called the *kilogram*.

Subsequent geodetic measures showed that the lengths of arcs differ on different parts of the earth and also that the value of the arc from which the meter was derived was in error by about one part in a thousand, causing a similar error in the length of the meter. Nevertheless the length of the original meter bar, known as the meter of the archives, has been retained, although its reference to the quadrant has been abandoned.

In 1875 an international bureau of weights and measures was established near Paris, France, by the concurrent action of the principal nations of the world for the purpose of constructing exact copies of the meter and kilogram deposited in the archives. Thirty-one standard meters of iridioplatinum and forty kilograms of the same alloy were constructed and carefully compared with the standards of the archives and with one another.

International Prototypes.—This great work was completed in 1889 and the meter and the kilogram which agreed most nearly with the original standards of the archives were called international prototypes and were deposited at the international bureau, where they are maintained to-day subject to the authority of the international committee on weights and measures.

The remaining meters and kilograms were distributed by lot to the different nations which contributed to the support of the bureau. The United States secured two copies of the meter and two copies of the kilogram, which are in the custody of the Bureau of standards at Washington. One of the meters known as No. 27 and one kilogram, No. 40, were selected as the United States standards, while the other meter and kilogram are used as working standards.

Determinations of the Units.—The length of the international meter has been determined in terms of the wave lengths of the red, green and blue radiations of cadmium, so that if every meter in the world were destroyed the length could be reproduced within less than one part in ten million. The number of wave lengths of the different radiations at 15 degrees centigrade and 760 millimeters pressure are as follows:

Red	1 m.	= 1,553,163.5
Green	1 m.	= 1,966,249.7
Blue	1 m.	= 2,083,372.1

The unit of capacity in the metric system is the *liter*, which was intended to be both equal to the volume of a cubic decimeter and to the volume of pure water under normal atmospheric pressure and at the temperature of maximum density (4°C.) that would exactly balance one kilogram in vacuo.

Extent of Use.—The use of the metric system is obligatory in France, Germany, Austria, Hungary, Belgium, Brazil, Bulgaria, Chili, Colombia, Denmark, Spain, Holland, Italy, Mexico, Montenegro, Peru, Portugal, Argentina, Roumania, Servia, Sweden, Norway, Switzerland, and Uruguay. Also in Cuba, the Philippine Islands, Porto Rico, and Guam. Its use is legal in the United States, Great Britain and possessions, in Russia, Japan, Egypt,

Bolivia, Greece, Guatemala, Nicaragua, Paraguay, Venezuela, Turkey, and Siam. The units of length, mass and capacity described are subdivided decimally and the Latin prefixes *milli*, *centi*, and *deci*, are used to indicate the order of the division, and multiplied by powers of ten, the order being indicated by the prefixes *deka*, *hecto*, *kilo* and *myria*.

THE METRIC SYSTEM AND ITS EQUIVALENTS.

Metric System	Equivalents in English Weights and Measures				
Measures of Length (Unit, meter)	Inches	Feet	Yards	Fathoms	Miles

NOTES FOR ENTIRE LEGAL WEIGHT TABLE

* Not defined.
a White beans.
b Green Apples.
c Shelled.
d Native.
e Undefined; dried 28 pounds.
f With stems; without stems, 64 pounds.
g Red and white; clover burr (for seed in Burr), 8 pounds; German Clover (also mere commonly called Crimson Clover), 60 pounds; Japan, Les Pedeza, in hulls, 25 pounds.
h Sweet unhulled, 33 pounds.
i Cannel coal.
j Husked.
k Corn in ear in Indiana, 70 pounds until Dec. 1st, next after grown; 68 pounds thereafter; in Texas, 70 pounds after Dec. 1st, and 72 pounds for new crop before Dec. 1st.
l In ear, 70 pounds from Nov. 1st, to May 1st, following, and from May 1st, to Nov. 1st, following, 68 pounds.
m With stems; without stems, 60 pounds.
n With stems.
o Unslacked; slacked, 40 pounds.
p Seventy pounds for a bushel of course saltor lime.
q Unslacked.
r Rye malt.
s Barley malt.
t Japanese barnyard millet, 35 pounds.
u Spanish onions, 30 pounds.
v Bottom sets, 32 pounds; in Kentucky, 36.
w Not stated whether dried or not.
x Dried.
y Black walnuts.
z Hulled.

COMMODITIES FOR WHICH BUSHEL WEIGHTS HAVE BEEN ESTABLISHED IN NOT MORE THAN THREE STATES.

Commodities	Weight	States
	Pounds	
Beggar weed	62	Florida
Blueberries (Dried)	42	Maine
Butternuts	28	Vermont
Cane Seed	50	Kansas and South Carolina.
Cantaloupe	50	North Carolina, South Carolina and Tennessee.
Chufas	54	Florida.
Cowpeas	60	Indiana, Maryland and Virginia.
Culm	80	Maryland.
Feed	50	Maine.
Feterita	56	Kansas.
Grass Seed, All Meadow and Fescue	14	North Carolina.
Grass Seed, Bermuda	40	New Mexico and Oklahoma; 14 pounds in North Carolina.
Grass Seed, Italian Rye	20	North Carolina, South Carolina and Tennessee.
Grass Seed, Johnson	28	Arkansas; 25 pounds in North Carolina.
Grass Seed, Perennial Rye	14	North Carolina.
Grass Seed, Rye	22	Nebraska.
Grass Seed, Sudan	40	Kansas; No. 1, 32 pounds; No. 2, 30 pounds; No. 3, 28 pounds in Texas.
Grass Seed, Tall Meadow, Tall Fescue	24	North Carolina.
Grass Seed, Velvet	7	North Carolina, South Carolina and Tennessee.
Guavas	54	Florida
India Wheat	46	Vermont
Land Plaster	100	North Carolina, South Carolina and Tennessee.
Lentils	60	Pennsylvania.
Mangel Wurzel	60	Connecticut and Maine.
Meal (Except Oatmeal)	50	Maine.
Middlings (Course)	30	Indiana.
Milo Maize	56	Kansas; 50 pounds in Texas.
Mustard Seed	58	North Carolina.
Parsley	8	Maine, New Hampshire and Vermont.
Peach Seed	50	North Carolina.
Peas, Blackeye and other Cowpeas	60	Virginia.
Radish Seed	50	Iowa and South Dakota.
Root Crops	50	Iowa, Nebraska and South Dakota.
Sage	4	North Carolina, South Carolina and Tennessee.
Salads	10	North Carolina; 12 pounds in South Carolina; 30 in Tennessee.
Sunflower Seed	24	North Carolina.
Teosinte	59	North Carolina.

Foreign Weights and Measures. — Japan.—In Japan the kwan, equal to 3.75 kilograms or 8.28 pounds avoirdupois, is the unit of mass. It is divided into 1,000 mommes, the mommes into 10 fuus and the fuu into 10 rins, the rin into 10 mos, and the mo into 10 shis.

The unit of length is the shaku, equal to $^{10}/_{33}$ (0.30303) meter, or 0.9941919 United States foot. The shaku is decimally divided into sun, bu, rin, mo, and shi. Multiples of the shaku are the ken, equal to 6 shaku; the cho, equal to 60 ken, and the pi, equal to 36 cho, or 12,960 shaku.

The shaku (land measure) is equal to 0.00033 are, or 0.988417534 square foot, 10 shaku equal 1 go and 10 gos equal 1 bu or tsubo, 30 bu equal 1 sé, 10 sé equal 1 tan, and 10 tan 1 cho.

The shaku (capacity measure) equals 0.01806 liter, or 0.180616 United States liquid quart, 10 shakus equal 1 go, 10 gos 1 sho, 10 shos 1 to, and 10 tos 1 koku. The metric weights and measures are

recognized as legal in accordance with the table of equivalents.

Russia.— The basis of Russian weights is the funt, equal to 0.40951241 kilogram, or 0.9028 pound avoirdupois. The funt is divided into 96 zolotniks or 32 loths, and the zolotnik is divided into 96 dolias; 40 funts equal 1 pood.

The basis of the length measure is the archine, equal to 28 inches or 0.71120 meter. The archine contains 16 verskops; 3 archines equal 1 sagene and 500 sagenes equal 1 verst.

The dessiatine, equal to 2,400 square soganes, or 2.6997 acres, is the unit for land measure.

The chetvert, equal to 2.09908 hectoliters, or 5.7748 United States bushels, is the unit for dry measure. The chetvert is divided into 8 chetveriks, and the chetverik into 8 garnetz. Twelve chetverts equal 1 lost.

The vedro, equal to 12.2993285 liters, or 3.249 United States gallons, is used for measuring liquids.

Chinese Measures.—The following gives the new system of weights and measures adopted by China in pursuance of the imperial rescript of August 28, 1908:

MEASURES OF LENGTH

Chinese.		Metric.
1 hao	=	0.0032 centimeter.
1 li	=	0.032 centimeter.
1 fen	=	0.32 centimeter.
1 tsun	=	3.2 centimeters.
1 chih	=	0.32 meter.
1 pu	=	1.6 meters.
1 chang	=	3.2 meters.
1 li	=	576.° meters.

MEASURES OF SURFACE

Chinese.		Metric.
1 hao	=	0.006144 are.
1 li	=	0.06144 are.
1 fen	=	0.6144 are.
1 fang pu	=	0.0256 are.
1 mu	=	6.144 ares.
1 ching	=	614.4 ares.

MEASURES OF CAPACITY

Chinese.		Metric.
1 shao	=	0.0104 liter.
1 ko	=	0.1035 liter.
1 sheng	=	1.0355 liters.
1 tou	=	10.355 liters.
1 hu	=	51.7734 liters.
1 tan or picul	=	103.5469 liters.

MEASURES OF WEIGHT

Chinese.		Metric.
1 hao	=	0.0037301 gram.
1 li	=	0.037301 gram.
1 fen	=	0.37301 gram.
1 chien	=	3.7301 grams.
1 liang	=	37.301 grams.
1 chin or catty	=	596.816 grams.

TABLE OF FOREIGN WEIGHTS AND MEASURES

Denominations	Where Used	American Customary Equivalents
Almude	Portugal	4.422 gallons
Ardeb	Egypt	7.6907 bushels
Are	Metric	0.02471 acre
Arobe	Paraguay	25 pounds
Arratel or libra	Portugal	1.011 pounds
Arroba (dry)	Argentine Republic	25.3175 pounds
	Brazil	32.38 pounds
	Cuba	25.3664 pounds
	Portugal	32.38 pounds
	Spain	25.36 pounds
	Venezuela	25.4024 pounds
Arroba (liquid)	Cuba, Spain and Venezuela	4.263 gallons
Arshine	Russia	28 inches
Arshine (square)	Russia	5.44 square feet
Artel	Morocco	1.12 pounds
Baril	Argentine Republic and Mexico	20.0787 gallons
Barrel	Malta (customs)	11.4 gallons
	Spain (raisins)	100 pounds
Batman or tabriz	Persia	6.49 pounds
Berkovets	Russia	361.12 pounds
Bongkal	India	832 grains
Bouw	Sumatra	7,096.5 square meters
Bu	Japan	0.119 inch
Butt (wine)	Spain	140 gallons
Caffiso	Malta	5.4 gallons
Candy	India (Bombay)	529 pounds
	India (Madras)	500 pounds
	Morocco	113 pounds
	Syria (Damascus)	575 pounds
	Turkey	124.7036 pounds
Cantaro (cantar)	Malta	175 pounds
Carga	Mexico and Salvador	300 pounds
Catty	China	1.316 pounds (avoir.)
	Japan	1.31 pounds
	Java, Siam and Malacca	1.35 pounds
	Sumatra	2.12 pounds
Centaro	Central America	4.2631 gallons
Centner	Bremen and Brunswick	117.5 pounds
	Darmstadt	110.24 pounds
	Denmark and Norway	110.11 pounds
	Nuremberg	112.43 pounds
	Prussia	113.44 pounds
	Sweden	93.7 pounds
	Vienna	123.5 pounds
	Zollverein	110.24 pounds
	Double or metric	220.46 pounds
Chetvert	Russia	5.7748 bushels
Chih	China	12.6 inches
Coyan	Sarawak	3,098 pounds
	Siam (Koyan)	2,667 pounds
Cuadra	Argentine Republic	4.2 acres
	Paraguay	78.9 yards
	Paraguay (square)	8.077 square feet
	Uruguay	Nearly 2 acres
Cubic meter	Metric	35.3 cubic feet
Cwt. (hundredweight)	British	112 pounds
Dessiatine	Russia	2.6997 acres
	Spain	1.599 bushels
Drachme	Greece	Half ounce
Egyptian weights and measures	(See Consular Reports No. 144)	
Fanega (dry)	Central America	1.5745 bushels
	Chili	2.575 bushels
	Cuba	1.599 bushels
	Mexico	1.54728 bushels
	Morocco	Strike fanega, 70 lbs.; full fanega, 118 lbs.
	Uruguay (double)	7.776 bushels
	Uruguay (single)	3.888 bushels
	Venezuela	1.599 bushels
Fanega (liquid)	Spain	16 gallons
Feddan	Egypt	1.03 acres
Frail (raisins)	Spain	50 pounds
Frasco	Argentine Republic	2.5096 quarts
	Mexico	2.5 quarts
Frasila	Zanzibar	35 pounds
Fuder	Luxemburg	264.17 gallons
Funt	Russia	0.9028 pound
Garnice	Russian Poland	0.88 gallon

Denominations	Where Used	American Customary Equivalents
Gram	Metric	15.432 grains
Hectare	Metric	2.471 acres
Hectoliter: Dry	Metric	2.838 bushels
Liquid	Metric	26.417 gallons
Joch	Austria-Hungary	1.422 acres
Ken	Japan	5.965 feet
Kilogram (kilo.)	Metric	2.2046 pounds
Kilometer	Metric	0.621376 mile
Koku	Japan	4.9629 bushels
Koree	Russia	3.5 bushels
Kwan	Japan	8.28 pounds
Last	Belgium and Holland	85.134 bushels
	England (dry malt)	82.52 bushels
	Germany	2 metric tons (4,480 pounds)
	Prussia	112.29 bushels
	Russian Poland	11¾ bushels
	Spain (salt)	4,760 pounds
League (land)	Paraguay	4,033 acres
Li	China	0.0126 inches
Libra (pound)	Argentine Republic	1.0127 pounds
	Central America	1.043 pounds
	Chili	1.014 pounds
	Cuba	1.0161 pounds
	Mexico	1.01465 pounds
	Peru	1.0143 pounds
	Portugal	1.011 pounds
	Spain	1.0144 pounds
	Uruguay	1.0143 pounds
	Venezuela	1.0161 pounds
Liter	Metric	1.0567 quarts
Livre (pound)	Greece	1.1 pounds
	Guiana	1.0791 pounds
Load	England (timber)	Square, 50 cubic feet; unhewn, 40 cubic feet; inch planks, 600 superficial feet
Manzana	Costa Rica	1 5-6 acres
	Nicaragua and Salvador	1.727 acres
Mare	Bolivia	0.507 pounds
Maund	India	82 2-7 pounds
Meter	Metric	39.37 inches
Mil	Denmark	4.68 miles
	Denmark (geographical)	4.61 miles
Milla	Nicaragua and Honduras	1.1493 miles
Morgen	Prussia	0.63 acre
Oke	Egypt	2.7225 pounds
	Greece	2.84 pounds
	Hungary	3.0817 pounds
	Turkey	2.82838 pounds
	Hungary and Wallachia	2.5 pints
Pic	Egypt	21¼ inches
Picul	Borneo and Celebes	135.64 pounds
	China, Japan and Sumatra	133⅓ pounds
	Java	135.1 pounds
	Philippine Islands	137.9 pounds
Pie	Argentine Republic	0.9478 foot
	Spain	0.91407 foot
Pik	Turkey	27.9 inches
Pood	Russia	36.112 pounds
Pund (pound)	Denmark and Sweden	1.102 pounds
Quarter	Great Britain	8.252 bushels
	London (coal)	36 bushels
	Argentine Republic	101.42 pounds
	Brazil	130.06 pounds
	Castile,* Chili, Mexico and Peru	101.41 pounds
Quintal	Greece	123.2 pounds
	Newfoundland (fish)	112 pounds
	Paraguay	100 pounds
	Syria	125 pounds
	Metric	220.46 pounds
Rottle	Palestine	6 pounds
	Syria	5¾ pounds
Sagene	Russia	7 feet
Salm	Malta	490 pounds
Se	Japan	0.02451 acre
Seer	India	1 pound 13 ounces
Shaku	Japan	11.9303 inches
		0.01806 liquid quart

TABLE OF FOREIGN WEIGHTS AND MEASURES—Continued

Denominations	Where Used	American Customary Equivalents
Sho	Japan	1.6 liquid quarts
Standard (St. Petersburg)	Lumber measure	165 cubic feet
Stone	British	14 pounds
Suerte	Uruguay	2,700 cuadras (see cuadra)
Sun	Japan	1.193 inches
Tael	Cochin China	590.75 grains (troy)
Tan	Japan	0.25 acre 9,884 sq. ft.
To	Japan	2 pecks
Ton	Space measure	40 cubic feet
Tonde (cereals)	Denmark	3.94783 bushels
Tondeland	Denmark	1.36 acres
Tsubo	Japan	98.84 square feet
Tsun	China	1.26 inches
Tunna	Sweden	4.5 bushels
Tunnland	Sweden	1.22 acres
Vara	Argentine Republic	34.1208 inches
	Central America	32.87 inches
	Chili and Peru	33.367 inches
	Cuba	33.384 inches
	Curacao	33.375 inches
	Mexico	33 inches
	Paraguay	34 inches
	Spain	0.914117 yard
	Venezuela	33.384 inches
Vedro	Russia	3.249 gallons
Vergees	Isle of Jersey	71.1 square rods
Verst	Russia	0.6629 mile
Vlocka	Russian Poland	41.98 acres

*Although the metric weights are used officially in Spain, the Castile quintal is employed in commerce in the peninsula and colonies, save in Catalonia; the Catalan quintal equals 91.71 pounds.

WEIGHTS AND MEASURES OF THE BIBLE

WEIGHTS

	Avoirdupois Lbs.	Oz.	Drs.	Troy. Lbs.	Oz.	Dwt.	Gr.
A gerah	0	0	0.439 =	0	0	0	12
10 gerahs = 1 bekah	0	0	4.39 =	0	0	5	0
2 bekahs = 1 shekel	0	0	8.78 =	0	0	10	0
60 shekels = 1 maneh	2	0	14.628 =	2	6	0	0
50 manehs = 1 talent	102	13	11.428 =	125	0	0	0

MEASURES

Long Measure	Feet	Inches
A digit, or finger (Jer. lii. 21)	0	0.912
4 digits = 1 palm (Exod. xxv, 25)	0	3.648
3 palms = 1 span (Exod. xxviii, 16)	0	10.944
2 spans = 1 cubit (Gen. vi, 15)	1	9.888
4 cubits = 1 fathom (Acts xxvii, 28)	7	3.552
1.5 fathoms = 1 reed (Ezek. xl, 3, 5)	10	11.328
13.3 reeds = 1 line (Ezek. xl, 3)	145	11.04

Land Measure	Eng. Miles	Paces	Feet
A cubit	0	0	1.824
400 cubits = 1 furlong (Luke xxiv, 13)	0	145	4.6
5 furlongs = 1 sabbath day's journey (John xi, 18; Acts i, 12)	0	727	3.0
10 furlongs = 1 mile (Matt. v, 41)	1	399	1.0
24 miles = 1 day's journey	33	76	4.0

Liquid Measure	Gallons	Pints
A caph	0	0.625
1.3 caphs = 1 log (Lev. xiv, 10)	0	0.833
4 logs = 1 cab	0	3.333
3 cabs = 1 hin (Exod. xxx, 24)	1	2
2 hins = 1 seah	2	4
3 seahs = 1 bath, or ephah (1 Kings vii, 26; John ii, 6)	7	4.5
10 ephahs = 1 kor, or homer (Isa. v, 10; Ezek. xiv, 14)	75	5.25

WEIGHTS AND MEASURES OF THE BIBLE—Continued

Dry Measure	Pecks	Gallons	Pints
A gachal	0	0	0.1416
20 gachals = 1 cab (2 Kings vi, 25; Rev. vi, 6)	0	0	2.8333
1.8 cabs = 1 omer (Exod. xvi, 36)	0	0	5.1
3.3 omers = 1 seah (Matt. xiii, 33)	1	0	1
3 seahs = 1 ephah (Ezek. xlv, 11)	3	0	3
5 ephahs = 1 letech (Hosea iii, 2)	16	0	0
2 letechs = 1 kor, or homer (Num. xi, 32; Hos. iii, 2)	32	0	0

N. B.—The foregoing table will explain many texts in the Bible. Take, for instance, Isa. v, 10. "Yea, ten acres of vineyard shall yield one bath, and the seed of an homer shall yield an ephah." This curse upon the covetous man was that 10 acres of vines should produce only 7 gallons of wine, *i. e.*, one acre should yield less than 3 quarts; and that 32 pecks of seed should only bring a crop of 3 pecks, or, in other words, that the harvest reaped should produce but one-tenth of the seed sown.

TIME

The natural day was from sunrise to sunset.

The natural night was from sunset to sunrise.

The civil day was from sunset one evening to sunset the next; for, "the Evening and the Morning were the first day."

Night (Ancient)	Day (Ancient)
First watch (Lam. ii, 19), till midnight.	Morning till about 10 a. m.
Middle watch (Judg. vii, 19), till 3 a. m.	Heat of day till about 2 p. m.
Morning watch (Exod. xiv, 24), till 6 a. m.	Cool of day till about 6 p. m.

Night (New Testament)	Day (New Testament)
First watch, evening = 6 to 9 p. m.	Third hour = 6 to 9 a. m.
Second watch, midnight = 9 to 12 p. m.	Sixth hour = 9 to 12 midday.
Third watch, cock-crow = 12 to 3 a. m.	Ninth hour = 12 to 3 p. m.
Fourth watch, morning = 3 to 6 a. m.	Twelfth hour = 3 to 6 p. m.

JEWISH MONEY

With its value in English and American money; the American dollar being taken as equal to 4s. 2d.

	English pound	s.	d.	American Dols.	Cents
A gerah (Exod. xxx, 13) =	0	0	1.36 =	0	2.73
10 gerahs = 1 bekah (Exod. xxxviii, 26) =	0	1	1.68 =	0	27.37
2 bekahs = 1 shekel (Exod. xxx, 13; Isa. vii, 23) =	0	2	3.37	0	54.74
50 shekels = 1 maneh =	5	14	0.75 =	27	37.50
60 manehs = 1 kikkar (talent) =	342	3	9 =	1,642	50
A gold shekel =	1	16	6 =	8	76
A kikkar of gold =	5,475	0	0 =	26,280	0

N. B.—A shekel would probably purchase nearly ten times as much as the same nominal amount will now. Remember that one Roman penny (8½d.) was a good day's wages for a laborer.

The Hebrew maneh, according to 1 Kings x, 17, compared with 2 Chron. ix, 16, contained 100 shekels; though according to one interpretation of Ezek. xiv, 12, it contained 60, but more probably 50. The passage reads thus: "Twenty shekels, five and twenty shekels, fifteen shekels shall be your maneh." This is variously interpreted: (1) 20 + 25 + 15 = 60. (2) 20, 25, 15 are different coins in gold, silver, and copper, bearing the same name. It is well to remark the meaning of these names: Shekel = simply, weight: Bekah = split, *i. e.*, the shekel divided into two: Gerah = a grain, as in our weights, a grain and a barleycorn, the original standard weight: Maneh = appointed, equivalent to sterling, a specific sum: Kikkar = a round mass of metal, *i. e.*, a weight or coin. Hebrew names of weights and coins are not found in the New Testament: *mna* in Luke xix, 13, is Greek, though possibly identical with the Hebrew *maneh*.

ROMAN MONEY

	English Pence		American Cents
A "farthing," quadrans (Matt. v, 26) = nearly	0.125	=	0.25
A "farthing," as in 4 quadrantes (Matt. x, 29) = nearly.	0.5	=	1
A "penny," denarius = 16 asses (Matt. xxii, 19) nearly.	8.50	=	17

The Roman sestertius = 2½ asses, is not named in the Bible.

N. B.—Here we learn that:—

Naaman's offering to Elisha of 6,000 pieces (shekels) of gold amounted to more than £10,000 = 48,000 dollars.

The Debtor (Matt. xviii, 24), who had been forgiven 10,000 talents, i. e., £3,000,000 = 14,400,000 dollars, refused to forgive his fellow-servant 100 pence *i. e.*, £3 10s. 10d = 17 dollars.

Judas sold our Lord for 30 pieces of silver, *i. e.*, £3 10s.8d. = 16 dollars 96 cents, the legal value of a slave, if he were killed by a beast.

Joseph was sold by his brethren for 20 pieces, *i. e.*, £2 7s. = 11 dollars 28 cents.

Time.—Three kinds of time are recognized by astronomers, *viz.*, sidereal, apparent solar and mean solar time.

Sidereal Time.—The sidereal day is the interval between two consecutive transits of some fixed celestial object across any given meridian, or it is the interval required by the earth to make one complete revolution on its axis. This interval is constant but it is inconvenient as a time unit because the noon of the sidereal day occurs at all hours of the day and night.

Apparent Solar Time.—The apparent solar day is the interval between two consecutive transits of the *sun* across any given meridian. On account of the variable distance between the sun and earth, the variable speed of the earth in its orbit, the effect of the moon, etc., this interval is not constant and consequently cannot be kept by any simple mechanism, such as a clock or watch.

Mean Solar Time.—To overcome the objection noted above, the mean solar day was devised. The mean solar day is the length of the average apparent solar day. Like the sidereal day it is constant, and like the apparent solar day its noon always occurs at approximately the same time of day.

The sidereal or astronomical day begins at mean noon and the hours run from one to twenty-four, while the civil day (mean solar) begins twelve hours earlier, at midnight, and the hours run from one to twelve, and then repeat from noon to midnight. The hours are in both cases divided into sixty minutes, and the minutes into sixty seconds.

The Year.—In dealing with longer periods, such as the life of a man, the day is too small a period, and for all chronological purposes the year has always been employed.

There are three different kinds of year used—the sidereal, the tropical, and the anomalistic.

The Sidereal Year is the time taken by the earth to complete one revolution around the sun from a given star to the same star again. Its length is 365 days 6 hours 9 minutes 9 seconds.

The Tropical Year is the time included between two successive passages of the vernal equinox by the sun, and since the equinox moves westward 50.2 seconds of arc a year the tropical year is shorter by 20 minutes 23.5 seconds in time than the sidereal year. As the seasons depend upon the earth's position with respect to the equinox, the tropical year is the year of civil reckoning.

Anomalistic Year.—The third kind of year is the anomalistic year—the interval between two successive passages of the perihelion, namely, the time of the earth's nearest approach to the sun. The anomalistic year is only used in special calculations in astronomy.

The Calendar.—Various attempts were made by the ancients to reconcile the month, which originally depended upon the changes of the moon, with the tropical year, but a satisfactory solution is not possible, and the calendars of civilized nations now disregard the moon entirely. The Mohammedan nations, however, still use a lunar calendar with a year of twelve lunar months, which alternately contain 355 and 356 days. According to their method of reckoning the same month falls

in different seasons, and their calendars gain one year on ours every thirty-three years.

The Julian Calendar, which was established 45 B. C., by Julius Cæsar, discarded all consideration of the moon and adopted 365¼ days as the true length of the year. He ordained that every fourth year should contain 366 days, and transferred the beginning of the year from March to January 1. The Julian calendar is still used in Russia and generally by the Greek church.

The Gregorian Calendar.—The true length of the tropical year is not 365¼ days, but 365 days 5 hours 48 minutes 45.5 seconds, a difference of 11 minutes 14.5 seconds by which the Julian year is too long. This amounts to a little more than three days in four hundred years, and consequently the date of the vernal equinox had in Pope Gregory's time fallen back to March 11th instead of occurring on March 21st as it did at the Council of Nice, A. D. 325. The pope therefore decreed that the calendar should be corrected by dropping ten days, so the day following October 4, 1582, should be called October 15th instead of October 5th, and also in the future only such century years shall be leap years as are divisible by 400. Thus 1700, 1800, 1900, etc., are not leap years, while 1600, 2000, 2400, etc., are. The change was immediately made by all Catholic countries, but it was not until 1752 that the Gregorian calendar was adopted by England.

Standard Time.—Prior to 1883 each city had its own time, which was determined by the time of passage of the sun across the local meridian. Consequently the traveler going from one city to another had to continually change his watch to the local time. Largely through the efforts of the railroads a system of standard time was introduced. According to this system the United States, which extends from 65 degrees to 125 degrees west longitude, was divided into four sections, each of 15 degrees longitude.

The *first* (or eastern) section includes all territory between the Atlantic coast and an irregular line drawn from Detroit, Mich., through Pittsburg to Charleston, S. C., its most southern point. The time of this section is that of the 75th meridian, which is five hours slower than Greenwich time.

The *second* (central) section includes all territory between the line mentioned and an irregular line drawn from Bismarck, N. D., to the mouth of the Rio Grande.

The *third* (mountain) section includes all territory between the last-named line and a line which passes through the western part of Idaho, Utah and Arizona.

The *fourth* (Pacific) section covers the rest of the country to the Pacific Ocean. Standard time is uniform in each of these sections, but the time in one section differs by exactly one hour from the section next to it. Thus the time of the first section is five hours slower than Greenwich time, the time of the central section six hours slower, the time of the mountain seven hours, and the time of the Pacific section is eight hours slower than Greenwich mean time.

In cities situated on the border line of two sections, as, for instance, Pittsburg and Atlanta, the standard times of both sections are used; for example, if at Pittsburg it is 7 a.m. eastern time, it is 6 a.m. central time, and in such cities when the time is given, it should be specified as eastern, central, etc.

The system of standard time has been practically adopted in almost all civilized countries. All continental Europe, except Russia, uses a time one hour faster than that of Greenwich; in Japan and Australia the time is nine hours faster, etc.

Temperature Scales.—Temperature is the term used to designate the state of a body as regards hotness or coldness. Two bodies are said to have the same temperature if, when they are put in contact, there is no tendency for one to get hotter while the other gets colder; if there is such a tendency, the one which tends to cool off is said to have the higher temperature.

A Scale of Temperature is a system of numbering temperatures, the numbers being larger as the temperatures are higher. Such scales are based upon two fixed temperatures, *viz.*, the "ice-point" or temperature at which pure ice melts, and the "steam point" or temperature at which pure water boils, both under the standard barometric pressure of 760 millimeters or 29.92 inches of mercury. Three such systems or scales are in use—the centigrade or Celsius, the Fahrenheit, and the Reaumur.

Centigrade.—On the centigrade scale, which is used almost universally in countries which have adopted the metric system of weights and measures, as well as in scientific work everywhere, the ice-point is numbered zero degrees (0° C.) and the steam-point one hundred degrees (100° C.), the unit of measurement, or the centigrade degree (1° C.) being the one-hundredth part of this interval.

Fahrenheit.—On the Fahrenheit scale, which is generally used in English-speaking countries, except among scientific men, the ice-point is numbered 32° F. and the steam-point 212° F., the difference being 180°, and the Fahrenheit degree (1° F.) being the one-hundred-eightieth part of this interval. The Fahrenheit degree is thus $\frac{100}{180}$ or $\frac{5}{9}$ as large as the centigrade degree. The Fahrenheit zero, at 32° below the ice-point, corresponding to $-\frac{5}{9} \times 32 = -17.8$°C., is approximately the lowest temperature that can be obtained with ordinary freezing mixtures of ice and common salt.

Reaumur.—The Reaumur scale is used in a few European countries, but is fast being superseded by the centigrade. It has 0° at the ice-point and 80° at the steam point, so that the Reaumur degree (1° R.) is $\frac{5}{4}$ of the centigrade degree or $\frac{9}{4}$ of the Fahrenheit degree.

Conversion.—*To convert from one scale to another* we have, in accordance with the above definitions, the following practical rules:

Centigrade to Fahrenheit; multiply by $\frac{9}{5}$ and add 32°.

Centigrade to Reaumur; multiply by $\frac{4}{5}$.

Fahrenheit to centigrade; subtract 32° and multiply by $\frac{5}{9}$.

Fahrenheit to Reaumur; subtract 32° and multiply by $\frac{4}{9}$.

Reaumur to centigrade; multiply by $\frac{5}{4}$.

Reaumur to Fahrenheit; multiply by $\frac{9}{4}$ and add 32°.

Care should be taken to make the addition or subtraction algebraically, *i. e.*, taking account of the negative sign when the temperature in question is below zero.

Absolute Temperature.—*By the absolute temperature* of a body is meant its temperature, measured in either of the three kinds of degrees, not from the ice-point or from the Fahrenheit zero, but from a point known as the absolute zero, which is at about —273.1°C. or—459.6°F. or—218.5°R. This mode of numbering temperatures is frequently convenient in scientific and engineering work. To convert centigrade temperatures into centigrade-absolute temperatures add 273.1°.

To convert from Fahrenheit to Fahrenheit-absolute add 459.6°. To convert from Reaumur to Reaumur-absolute add 218.5°. To convert in the other direction, subtract the same amounts. The Reaumur-absolute scale is seldom or never used, and the Fahrenheit-absolute scale only by engineers in English-speaking countries. When the term "absolute temperature" is used without further qualification, it usually means the centigrade temperature plus 273°, though this value, which may also be looked upon as the centigrade-absolute temperature of the ice-point, is sometimes taken as high as 274°.

Barometric Measurements.—By barometer reading is meant the height in inches or millimeters of the column of mercury, under standard conditions, that exactly balances the pressure exerted by the atmosphere at the instant the reading is made. The pressure exerted by a given column of mercury depends upon the altitude of the barometer, and upon the latitude, and it is customary, in order to get accurate comparisons, to refer the readings to latitude 45°, and to sea level. Also since the density of the mercury is affected by the temperature it is usually referred to 0° centigrade.

Since all air movements are the result of difference in pressure, important conclusions regarding the weather to be expected may be deducted from barometric readings, hence their use by mariners and weather experts.

Their value in determining altitudes depends upon the fact that the pressure of the atmosphere decreases with the altitude according to a fairly well established law, which is illustrated by the following table:

PRESSURE OF THE ATMOSPHERE AT DIFFERENT ELEVATIONS

Elev. Feet	Barom. Inches	Elev. Feet	Barom. Inches	Elev. Feet	Barom. Inches
0	29.9	600	29.25	4000	25.81
50	29.845	700	29.14	5000	24.88
100	29.79	800	29.03	6000	23.98
200	29.68	900	28.92	7000	23.11
300	29.57	1000	28.82	8000	22.28
400	29.46	2000	27.78	9000	21.48
500	29.35	3000	26.78	10000	20.70

Beaufort's Wind Scale.—The Beaufort Scale is used by seamen for recording the force of wind. For the guidance of those unaccustomed to its use, the corresponding velocity per hour in statute miles and in nautical miles is added. The force of wind varies from 0, a calm, to 12, a hurricane.

Intensity of Force of Wind — Beaufort's Scale	Velocity Statute miles per hour	Velocity Nautical miles per hour
0. **Calm.** Full rigged ship, all sail set, no headway	0 to 3	0 to 2.6
1. **Light Air.** Just sufficient to give steerageway	8	6.9
2. **Light Breeze.** Speed of 1 or 2 knots, "full and by."	13	11.3
3. **Gentle Breeze.** Speed of 3 or 4 knots, "full and by."	18	15.6
4. **Moderate Breeze.** Speed of 5 or 6 knots, "full and by."	23	20.0
5. **Fresh Breeze.** All plain sail, "full and by."	28	24.3
6. **Strong Breeze.** Topgallant sails over single-reefed topsails	34	29.5
7. **Moderate Gale.** Double-reefed topsails	40	34.7
8. **Fresh Gale.** Treble-reefed topsails (or reefed upper topsails and courses)	48	41.6
9. **Strong Gale.** Close-reefed topsails and courses (or lower topsails and courses)	56	48.6

Intensity or Force of Wind — Beaufort's Scale	Velocity Statute miles per hour	Velocity Nautical miles per hour
10. **Whole Gale.** Close-reefed main topsail and reefed foresail (or lower main top-sail and reefed foresail)	65	56.4
11. **Storm.** Storm staysails	75	65.1
12. **Hurricane.** Under bare poles	90 and over	78.1 and over

The word "force" used in connection with this scale has no relation to pressure, but refers to speed or velocity.

Speed of Winds in the United States.—United States weather bureau records of the average speed of wind in miles per hour at selected stations, and the highest speeds ever reported for a period of five minutes.

Station	Average	Highest
Abilene, Texas	11	66
Albany, New York	6	70
Alpena, Michigan	9	72

*Anemometer blew away at a velocity of 84 miles per hour, September, 1900.

Values of Foreign Coins.—The following values of foreign coins in terms of the United States gold dollar were established by the treasury department in October, 1910, for estimating the value of all foreign merchandise exported to the United States:

VALUE OF FOREIGN COINS PRIOR TO ABANDONMENT OF GOLD STANDARD, 1933.

Country	Standard	Monetary Unit	Value in Terms of U. S. Gold Dollar	Coins
Argentine Republic	Gold	Peso	$0.965	Gold: argentine ($4.824) and ½ argentine. Silver: peso and divisions.
Austria-Hungary	Gold	Crown	.203	Gold: 10 and 20 crowns. Silver: 1 and 5 crowns.
Belgium	Gold	Franc	.193	Gold: 10 and 20 francs. Silver: 5 francs.
Bolivia	Gold	Boliviano	.389	Gold: *Silver boliviano and divisions.
Brazil	Gold	Milreis	.546	Gold: 5, 10, and 20 milreis. Silver: ½, 1, and 2 milreis.
British Possessions, N. A. (except Newfoundland).	Gold	Dollar	1.000	
Central American States—				
Costa Rica	Gold	Colon	.465	Gold: 2, 5, 10, and 20 colons ($9.307). Silver: 5, 10, 25, and 50 centimos.
British Honduras, Guatemala, Honduras, Nicaragua, Salvador	Gold	Dollar	1.000	
	Silver	Peso	.383	Silver: peso and divisions.
Chile	Gold	Peso	.365	Gold: escudo ($1.825), doubloon ($3.650) and condor ($7.300) Silver: peso and divisions.
China	Silver	Tael—Amoy	.629	
		Tael—Canton	.627	
		Tael—Cheefoo	.601	
		Tael—Chin Kiang	.614	
		Tael—Fuchau	.581	
		Tael—Haikwan (customs)	.640	
		Tael—Hankow	.588	
		Tael—Kiaochow	.609	
		Tael—Nankin	.622	
		Tael—Niuchwang	.589	
		Tael—Ningpo	.604	
		Tael—Peking	.613	
		Tael—Shanghai	.574	
		Tael—Swatow	.581	
		Tael—Takau	.633	
		Tael—Tientsin	.609	
		Dollar—Hongkong	.413	
		Dollar—British	.413	
		Dollar—Mexican	.416	
Colombia	Gold	Dollar	1.000	Gold: condor ($9.647) and double condor. Silver: peso.
Denmark	Gold	Crown	.268	Gold: 10 and 20 crowns.
Ecuador	Gold	Sucre	.487	Gold: 10 sucres ($4.8665). Silver: sucre and divisions.
Egypt	Gold	Pounds (100 piasters)	4.943	Gold: pound (100 piasters), 5, 10, 20, and 50 piasters. Silver: 1, 2, 5, 10, and 20 piasters.
Finland	Gold	Mark	.193	Gold: 20 marks ($3.859), 10 marks ($1.93).
France	Gold	Franc	.193	Gold: 5, 10, 20, 50, and 100 francs. Silver: 5 francs.
German Empire	Gold	Mark	.238	Gold: 5, 10, and 20 marks.
Great Britain	Gold	Pound sterling	4.866½	Gold: sovereign (pound sterling) and ½ sovereign.
Greece	Gold	Drachma	.193	Gold: 5, 10, 20, 50, and 100 drachmas. Silver: 5 drachmas.
Hayti	Gold	Gourde	.965	Gold: 1, 2, 5, and 10 gourdes. Silver: gourde and divisions.
India (British)	Gold	Pound sterling†	4.866½	Gold: sovereign (pound sterling). Silver: rupee and divisions.
Italy	Gold	Lira	.193	Gold: 5, 10, 20, 50, and 100 lire. Silver: 5 lire.
Japan	Gold	Yen	.498	Gold: 5, 10, and 20 yen. Silver: 10, 20, and 50 sen.
Liberia	Gold	Dollar	1.000	
Mexico	Gold	Peso‡	.498	Gold: 5 and 10 pesos. Silver: dollar § (or peso) and divisions.
Netherlands	Gold	Florin	.402	Gold: 10 florins. Silver: 2½, 1 florin and divisions.
Newfoundland	Gold	Dollar	1.014	Gold: 2 dollars ($2.028).
Norway	Gold	Crown	.268	Gold: 10 and 20 crowns.
Panama	Gold	Balboa	1.000	Gold: 1, 2½, 5, 10, and 20 balboas. Silver: peso and divisions.
Persia	Silver	Kran	.072	Gold: ½, 1, and 2 tomans ($3.409). Silver: ¼, ½, 1 2 and 5 krans
Peru	Gold	Libra	4.866½	Gold: ½ and 1 libra. Silver: sol and divisions.
Philippine Islands	Gold	Peso	.500	Silver peso: 10, 20, and 50 centavos.
Portugal	Gold	Escudo	1.080	Gold: 1, 2, 5, and 10 milreis.
Russia	Gold	Ruble	.515	Gold: 5, 7½, 10, and 15 rubles. Silver: 5, 10, 15, 20, 25, 50 and 100 copecks.
Spain	Gold	Peseta	.193	Gold: 25 pesetas. Silver: 5 pesetas.
Straits Settlements	Gold	Pound sterling¶	4.866½	Gold: sovereign (pound sterling). Silver: dollar and divisions.
Sweden	Gold	Crown	.268	Gold: 10 and 20 crowns.
Switzerland	Gold	Franc	.193	Gold: 5, 10, 20, 50, and 100 francs. Silver: 5 francs.
Turkey	Gold	Piaster	.044	Gold: 25, 50, 100, 250, and 500 piasters.
Uruguay	Gold	Peso	1.034	Gold: peso. Silver: peso and divisions.
Venezuela	Gold	Bolivar	.193	Gold: 5, 10, 20, 50, and 100 bolivars. Silver: 5 bolivars.

Note.—The coins of silver-standard countries are valued by their pure silver contents, at the average market price of silver for the three months preceding the date of this circular.

*Gold standard adopted December 31, 1908, 12½ bolivianos equal the pound sterling or Peruvian pound ($4.866½).

†The sovereign is the standard coin of India, but the rupee ($0.3244½) is the current coin, valued at 15 to the sovereign.

‡Seventy-five centigrams fine gold.

§Value in Mexico, $0.498.

¶The current coin of the Straits Settlements is the silver dollar issued on government account and which has been given a tentative value of $0.567758½.

English Money.—The unit is the pound sterling or sovereign, which is equal to $4.8665 at a normal rate of exchange.

4 farthings (far.) = 1 penny (d.) equals $.0202 plus.

12 pence = 1 shilling (s.) equals $.2433 plus.

20 shillings = 1 pound (£) equals $4.8665.

Canadian Money.—The coinage system of Canada is very similar to that of the United States. Canadian currency is on a decimal scale. The unit of coinage is the dollar and decimal parts of the dollar are expressed in cents as in the United States. There are no Canadian gold coins, but those of Great Britain and the United States are in circulation.

French Money.—The money of France is on a decimal scale. The unit of value is the franc, valued at $.193 in United States money, at normal rate of exchange.

Table.—

10 millimes (ms.)	= 1 centime.....ct.
10 centimes	= 1 decime.....de.
10 decimes	= 1 franc.....fr.

German Money.—The principal units of German money are the mark and pfennig. 100 pfennig (pf.) = 1 mark (M.). The mark contains 5.5513 grains of pure gold, and is therefore equal to $.238 at normal rate of exchange.

Explanation of Leap Year.—The earth requires 365 days, 5 hours, 48 minutes, and 49.7 seconds to complete its revolution around the sun. This is a little less than 365¼ days, so by considering 3 successive years as common years of 365 days each and the fourth as a leap year of 366 days there is a gain of time. To correct this, the extra day is added to only every fourth centennial year. From the foregoing we derive the following statements for the deciding of leap years.

1. All years divisible by 4, except centennial years, are leap years.

2. All centennial years divisible by 400 are leap years.

Table of Months in the Year.—

No.	Month	Abbr.	Days.
1	January	Jan.	31
2	February	Feb.	28 or 29
3	March	Mar.	31
4	April	Apr.	30
5	May	.....	31
6	June	.....	30
7	July	.....	31
8	August	Aug.	31
9	September	Sept.	30
10	October	Oct.	31
11	November	Nov.	30
12	December	Dec.	31

Note.—The month should be known by its number.

Circular Measure.—

60 seconds of arc (″)	= 1 minute of arc (′).
60 minutes	= 1 degree.....(°).
30 degrees	= 1 sign.....S.
12 signs	= 1 circle.....Cir.
60 degrees	= 1 sextant.
90 degrees	= 1 quadrant or right angle.

Notes.—1. Minutes of the earth's circumference are nautical miles.

2. Every circle, great or small, is divisible into the same number of parts, but a division of one circle is not necessarily equal to a division of another, although it has the same name. Thus, every circle has 360 degrees, but a degree of one circle is not equal to a degree of every other circle.

MISCELLANEOUS MEASURES

Books.—The size of the page depends upon the number of times the sheet is folded. A sheet folded into—

2	leaves	making	4	pages,	is called a Folio
4	"	"	8	"	" a Quarto, or 4to.
8	"	"	16	"	" an Octavo, or 8vo.
12	"	"	24	"	" a 12mo.
16	"	"	32	"	" a 16mo.
18	"	"	36	"	" an 18mo.
24	"	"	48	"	" a 24mo.
32	"	"	64	"	" a 32mo.

1 size=⅛ inch. Used by shoemakers.

Paper Measure. Table.—

24 sheets	=1 quire....qr.
20 quires	=1 ream....rm.
2 reams	=1 bundle...bdl.
5 bundles	=1 bale.....bl.

Counting. Table.—

20 units	=1 score.
12 units	=1 dozen.....doz.
12 dozen	=1 gross.....gro.
12 gross	=1 great gr...gr. gro.

Metric System.—The Metric System is a decimal system of weights and measures, the principal unit of which is the meter.

1. The Metric System, which was first introduced in France, is required by law in South America, in parts of Asia, in nearly all European countries, and is legalized by Great Britain, Russia, and the United States.

2. The meter is a trifle less than one ten-millionth part of the distance measured on a meridian of the earth from the equator to the pole, and is equal to 39.37079, or 39.37 inches.

3. The standard meter (of which nearly every civilized nation has procured a copy) is a bar of platinum carefully preserved at Paris.

The Metric System has a number of advantages over our present system, some of which are:

1. It has only five primary units, viz: meter, square meter, cubic meter, liter, and gram.

2. Each primary unit suggests its measure.

3. It does away with the system of compound num ers.

4. As all divisions and multiplications are by 10, or based on the decimal system, it makes all computations relating to measure simpler.

5. It facilitates commerce and exchange by giving all nations a uniform system of weights and measures.

6. It is simpler, more concise, and yet, complete.

The Lower Denominations or Divisions of the primary unit are denoted by the Latin prefixes milli (1/1000), centi (1/100), and deci (1/10), while the Higher Denominations or Multiples are denoted by the Greek prefixes deka (10), hekto (100), kilo (1000), and myria (10000).

By knowing the unit of weight or measurement, it is very simple to prepare the tables, as we use the same prefixes in each case.

In the tables, the abbreviations for divisions often begin with small letters, while those for multiples begin with capital letters.

Wood Measure.—The unit is the *stere*, which is equivalent to the cu. meter.

10 Decisteres (ds.) =1 Stere (1 cu. meter).
10 Steres (s.) =1 Dekastere (10 cu. meters).

Reduction of Denominate Numbers.—

Reduction of denominate numbers is the process of changing from one denomination to another without changing the value.

Reduction descending is the process of changing from a higher to a lower denomination. Reducing 8 bushels to quarts is an example of reduction descending.

Reduction ascending is the process of changing from a lower to a higher denomination. Reducing 93678 pounds to tons, etc., is an example of reduction ascending.

Reduction Descending.—

Example 1. Reduce 2 miles 164 rods 2 yards to feet.

Solution:

mi.	rd.	yd.
2	164	2
320		
640		
164		
804 rd.		

Solution Continued

804 rd.
5½
402
4020
2
4424 yd.
3
13272 ft.

Explanation.—Since 1 mile=320 rods, multiply 2 by 320 and to the product add the given number of rods. Thus, 2×320 +164=804.

Since 1 rod=5½ yards, multiply 804 by 5½ and then add the given number of yards. Thus, 804×5½+2=4424.

Since 1 yard=3 feet, multiply 4424 by 3 to find the number of feet.

Reduction Ascending.—

Example 1. Reduce 6212 pence to higher denominations.

Solution.

12)6212d
20)517s+8d.
£25+17s.
£25 17s. 8d.

Explanation.—Since it takes 12 pence to make 1 shilling, there are as many shillings as 12 is contained times in 6212, or 517, and there is a remainder of 8. The result is 517s. 8d. The remainder has the same name as the dividend.

Since it takes 20 shillings to make 1 pound, there are as many pounds as 20 is contained times in 517, or 25, and there is a remainder of 17. The result of this division is £25 17s.

The equivalent higher denominations are £25 17s. 8d.

Addition of Compound Numbers.—

Example 1. Find the sum of 35 bu. 2 pk. 5 qt.; 29 bu. 3 pk. 7 qt.; 18 bu. 4 qt.; 19 bu. 3 pk.; and 37 bu. 1 pk. 7 qt.

Solution:

bu.	pk.	qt.
35	2	5
29	3	7
18	0	4
19	3	0
37	1	7
140	3	7

4)11 8)23
2+3 2+7

Explanation.—Write the numbers to be added, placing like denominations in the same column. Beginning at the right, add the first column. If the sum equals one or more of the next higher denomination, it must be reduced. Thus, 23 qt. equal 2 pk. and 7 qt. Write the remainder, 7 qt., under the first and carry 2 pk. to the next column. Treat each column in the same manner.

Subtraction of Compound Numbers.—

Subtraction involves reduction descending.

Illustrations.

	(1)			(2)	
	5 bu.	3 pk.	6 qt.	5 T. 7 cwt.	16 lb.
	2	1	3	2 5	46
Differences	3 bu.	2 pk.	3 qt.	3 T. 1 cwt.	70 lb.

Reduce 1 cwt. of the minuend to pounds. 116 lb.−46 lb.=70 lb.; 6 cwt.−5 cwt.= 1c wt., etc.

Multiplication of Compound Numbers. *Example*: Multiply 14 days 2 hours 21 minutes 29 seconds by 9.

Solution.

da.	hr.	min.	sec.
14	2	21	29
			9
126	21	13	21
	189		60)261
	4		4+21
	60)193		
	3+13		

Explanation.—Write the number as indicated and multiply, beginning with the lowest denomination. If the product equals 1 or more of the next higher denomination, divide it by the number necessary to make one of that denomination. Write the remainder, if there is one, under the first column and add the quotient to the product of the second column. Treat each column in like manner.

Division of Compound Numbers.—In division of denominate numbers the divisor may be either abstract or denominate.

Illustrations. (1) Compute the cost, per yd., of 80 yd. cloth invoiced at £180.

Solution (a).

80)£180

£ 2.25 = £2 5s. (cost).

Solution and Analysis (b). The cost per yd. is evidently 1/80 of £180. 1/80 of £180 = £2 and a remainder of £20. £20 = 400s. 1/80 of 400s. = 5s. 1/80 of £180 = £2 5s.

AREAS AND VOLUMES OF VARIOUS FIGURES

Parallelograms.—The area of any parallelogram is equal to the product of its base by its altitude.

Triangles.—The area of any triangle is equal to one-half the product of its base multiplied by its altitude.

The square of the hypotenuse of a right-angle triangle is equal to the sum of the squares of the other two sides. Therefore, to find the hypotenuse when the other two sides are given, find the sum of the squares of the two sides and extract the square root. To find the side when one side and the hypotenuse are given, subtract the square of the given side from the square of the hypotenuse and extract the square root of the remainder.

Circles.—The circumference of a circle is the diameter multiplied by 3.1416. For approximate results, 3 1/7 may be used instead of 3.1416.

The circumference divided by 3.1416 equals the diameter.

The area of a circle may be found in one of three ways:

1. The circumference multiplied by one-half the radius.

2. The square of the radius multiplied by 3.1416.

3. The square of the diameter multiplied by ¼ of 3.1416 (.7854).

To find the diameter of a circle whose area is given, divide the area by ¼ of 3.1416 (.7854) and extract the square root of the quotient. To find the circumference, multiply the diameter by 3.1416.

Prism or Cylinder.—To find the volume of a prism or cylinder, multiply the area of the base by the altitude. The result will be expressed in cube units.

To find the lateral surface of a prism or cylinder, multiply the perimeter of the base by the altitude.

To find the entire surface, add the area of the lateral surfaces to the area of the two bases.

Pyramid or Cone.—To find the volume of a pyramid or of a cone, multiply the area of the base by one-third the altitude. The result will be in cube units.

To find the lateral surface of a pyramid or cone, multiply the perimeter of the base by one-half the *slant* height.

To find the entire surface, add the lateral surface to the area of the base.

TYPICAL PROBLEMS AND SOLUTIONS IN PRACTICAL MEASUREMENTS

Measures of Time.—*Example*: Find the time by compound subtraction from Oct. 17, 1919, to May 15, 1922.

Solution.

1922— 5—15	
1919—10—17	15+30−17 = 28 da.
2— 6—28	4+12−10 = 6 mo.

Explanation.—Write the later date as the minuend, the earlier as the subtrahend, and subtract as in compound numbers.

The months are represented by their numbers. Thus, May being the fifth month is represented by 5 and likewise October by 10. The years and days are written as given.

Counting back or forward from a given date.

Example 1: Count forward 183 days from Nov. 30, 1922.

Example 2: Count back 145 days from Oct. 1, 1923.

Solutions.

1.	183 da.		93 da.
	0 Nov.		31 Mar.
	183		62
	31 Dec.		30 Apr.
	152		32
	31 Jan.		31 May
	121		1 June
	28 Feb.		June 1, 1923.
	93		
2.	145 da.		Proof
	1 Oct.		
	144		31
	30 Sept.		9
	114		22 M.
	31 Aug.		30 J.
	83		
	31 July		31 J.
	52		31 A.
	30 June		30 S.
	22		1 O.
			145 da.

May 31 − 22 = May 9, 1923.

Notes.— 1. In counting back, as shown above, we start with the later date and count it.

2. When the time is expressed in months, calendar months are meant. In counting back or forward a number of months from a given date the corresponding day of another month is found. Thus, 5 mo. forward from May 15 gives Oct. 15 (5th mo. + 5 = 10th mo.). Four months back from Aug. 27 is Apr. 27 (8th mo. − 4 = 4th mo.).

3. When counting calendar months forward, if there is not a corresponding day in the month to which we reckon, the last day of that month is taken. Thus, July 31 + 2 mo. = Sept. 30; Jan. 31 + 1 mo. = Feb. 28.

4. The time to be counted is often 30, 60, or 90 days. The correct dates in such cases can be found mentally by adding by 30's as follows:

(a.) The addition of 30 days to any date in a 30-day month produces the same date in the next succeeding month.

(b.) The addition of 30 days to any date (except the first) in a 31-day month produces 1 day less in the next succeeding month. By adding 30 days to the first of a 31-day month the last of that month is found. By adding 30 days to the 30th or 31st of January of a common year the 1st or 2nd of March is found, but in a leap year the same addition would bring Feb. 29 or Mar. 1.

(c.) The addition of 30 days to any date in February of a common year gives a date two days later in March but only 1 day later in a leap year.

(d.) The same rules can be applied in counting back, but the date is decided by the number of days in the preceding month.

Carpeting.—Carpet is made in various widths, the more common being 27 in. and 36 in. It is sold by the yard in length regardless of its width.

In estimating the number of yards of carpet required for a room, the "strip method" is generally used. The strips are laid either lengthwise or crosswise, and as there is usually some waste in matching the pattern, it is necessary to buy more carpet than would otherwise be required to cover the floor.

Example:—How many yards of carpet 27 in. wide will be required for a room 18′ 9″ long and 16′ 4″ wide, if the strips run lengthwise and 9 inches per strip are allowed for matching?

Solution.

16′ 4″ = 196 in.
196 ÷ 27 = 7 7/27 or 8 strips.
18′ 9″ + 9″ = 19½′, length of 1 strip.
19½′ × 8 = 156′, total length.
156 ft. ÷ 3 = 52 yd. carpet.

Explanation.—Since the strips run lengthwise, each strip covers 27 inches of the width of the floor. The number of strips is found by dividing the width of the room by the width of one strip. In this case 7 strips leave uncovered a strip 7 in. wide extending the entire length of the room, to cover which an additional strip must be purchased. Every strip must be as long as the room is *long*, and since 9 in. is wasted in matching, each strip must be purchased 9 in. longer than the room, or 18′ 9″ + 9″ = 19½ ft. The entire length of carpet is found by multiplying the length of each strip by the number of strips required. The length is then reduced to yards.

Papering.—Wall paper is put up in single rolls 8 yards long and in double rolls 16 yards long. For a room of ordinary height, 5 strips can be cut from a double roll but only 2 from a single roll. Therefore, double rolls are more economical than single rolls.

American wall paper is generally 18 inches wide, and unless otherwise stated that width is used in this work. Imported papers are of various widths.

If there was no waste in papering, the number of rolls could be found by dividing the area to be papered by the area of one roll. This method is not practical, however, and paper-hangers use the method explained in the following example.

Example: How many double rolls of paper will be required for the walls of a room 24 ft. long, 19 ft. wide, and 9 ft high, if 36 ft. are deducted for the width of doors, windows, mantels, etc.?

Perimeter of room = 24 × 2 = 48 ft. + 19 × 2 = 38 ft. = 86 ft.

86′ − 36′ = 50 feet of wall to be papered.

1 strip of paper is 18 in. or 1½ ft. wide.
50÷1 1/2=50×2/3=100/3=33 1/3 or 34 strips required.
Each roll=16 yd.=48 ft. long.
Each strip must be 9 ft., the height of the room.
48÷9=5 1/3 or 5 strips from 1 roll.
34÷5=6 4/5 or 7 rolls required.

Finding the Number of Board Feet.—When lumber is 1 inch or less in thickness, to find the number of board feet, *multiply the length in feet by the width in inches and divide the product by 12.*

Note—When the width is given in feet it is not necessary to divide by 12.

When more than 1 inch thick, *multiply the length in feet by the width and thickness in inches and divide by 12.*

In measuring inch material, every inch of the width of a board 12 ft. long is a board foot. This is often taken as a basis of measurement in selling lumber at the yard. When the length is uniform but the boards are of various widths, the entire width of the boards is measured and from this the correct number of board feet can readily be found. Thus, if the boards are 15 ft. long, every inch of the width is 1 1/4 bd. ft.; if 16 ft. long and 2 in. thick, every inch of the width is 1 1/3×2 or 2 2/3 board feet.

A pile of lumber can be measured by finding the number of cubic feet and then, by multiplying by 12, the number of board feet can be found.

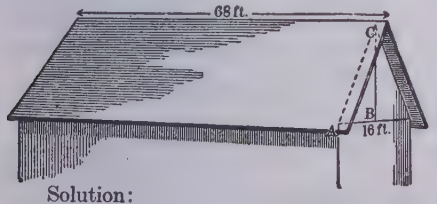
Hewn or round timber is sometimes measured by cubic measure.

Example 1. How many board feet are there in a board 15 ft. long, 8 in. wide, and 1 in. thick?

Solution:
15×8=120
120÷12=10=10 bd. ft.

Or, by cancellation,

$$\frac{\overset{5}{\cancel{15}}\times\overset{2}{\cancel{8}}}{\underset{1}{\cancel{12}}}=10 \text{ bd. ft.}$$



Example 2. How many feet, board measure, are there in a plank 15 ft. long, 10 in. wide, and 2 in. thick?

Solution:
15×10×2=300
300÷12=25=25 bd. ft.

Or, by cancellation,

$$\frac{\overset{5}{\cancel{15}}\times\overset{5}{\cancel{10}}\times\overset{1}{\cancel{2}}}{\underset{1}{\cancel{12}}}=25 \text{ bd. ft.}$$

The accompanying diagram represents the roof of a shed 16 ft. wide. If the ridge-pole is 68 ft., the pitch of the roof one half, and the projection of the rafters 18 in., how many shingles 16 in. long, laid 4½ in. to the weather, will be required to cover the roof?

Solution:
½ of 16 ft.=8 ft.=the base of the triangle *ABC*.

The pitch of the roof is ½; ½ of 16 ft.=8 ft.=the altitude of the triangle *ABC*. $8^2+8^2=128$; $128^1=11.31$, number of feet in the hypotenuse of *ABC*.

18 in.=1.5 ft.; 11.31 ft.+1.5 ft.=12.81 ft.=the length of the rafters or the width of each side of the roof.

2×68×12.81 ft.=1742.16 sq. ft.=the entire surface of the roof.

1742.16 sq. ft.=17.4216 squares; 17.4216×800 shingles=13937 shingles.

As bundles of shingles are not broken it will be necessary to buy 14000 shingles.

Excavation.—

Example: Find the cost of digging a cellar 30 ft. long, 24 ft. wide, and 7½ ft. deep, at 21c per cubic yard.

Solution:
30×24×7½=5400 cu. ft.
5400÷27 = 200 cu. yd.
200 cu. yd. @ 21c.=$42.00

Or, by cancellation,

$$\frac{\overset{10}{\cancel{30}}\times\overset{8}{\cancel{24}}\times\overset{5}{\cancel{15}}\times 21}{\underset{1}{\cancel{27}}\ \underset{9}{\cancel{2}}\ \underset{1}{\cancel{2}}}=4200=\$42.00$$

Explanation.—The product of length, breadth, and thickness is the number of cubic feet of earth to be thrown out in digging the cellar. Reduce the cubic feet to cubic yards by dividing by 27 and then multiply by the price per cubic yard.

In the solution by cancellation, all multipliers are written above the line and all divisors below the line.

Cylindrical.—How many gallons will fill a cylindrical tank 4 ft. in diameter and 12 ft. deep?

Solution:

4	192
4	5 7/8
16	168
12	960
192	1128=1128 gal.

Explanation.—Every unit of the capacity of a cylinder found by squaring the diameter and multiplying by the height is .7854 of a cubic foot. Since a cubic foot holds 7.48 gal., a unit of the cylinder holds .7854 of 7.48 gal.=5.87479 or 5 7/8 gal.

PERCENTAGE

Use.—Nearly all of the fractional relations in business are expressed in per cent. Percentage has a very wide and varied application in the different business activities. The business man is more likely to talk of per cents than of fractional parts.

Definition.—Per cent are two words derived from the Latin per centum, meaning by the hundred or hundredths. Percentage is, therefore a name applied to calculations in which fractional parts of a hundred are used as the basis. It is clear, therefore, that percentage is simply a special application of decimal fractions in which the indicated denominator is always 100.

Terms Used in Percentage:—

BASE. The number of which a number of hundredths or per cents are taken is called the base.

Example: 8% of 300=24. 300 is the base.

RATE is the number of per cents or hundredths taken. In the above example, 8 is the rate.

PERCENTAGE is the product of the rate times the base. In the above example, 24 is the percentage.

The AMOUNT is the sum of the base and the percentage.

The DIFFERENCE is the base minus the percentage.

Aliquot Parts and Percentage.—Since the indicated denominator is always 100 in percentage, it is frequently possible and advantageous to make use of the aliquot parts of 100 when working percentage. Care must be exercised in placing the decimal point in the result.

PROBLEMS IN PERCENTAGE are solved in accordance with the fundamental processes in handling decimal fractions. These problems may be grouped under these three headings:

1. Rate×base=percentage,
   Then, transposing,
2. Percentage÷base=rate
   And
3. Percentage÷rate=base.

To find the percentage:

When the base and rate are given and the percentage is to be found, express the rate as a decimal and multiply the base by it.

Example: Find 6% of $400.00.
6%=.06. Therefore, 6% of $400.00=.06×$400.00=$24.

To find the rate:

When the base and percentage are given and the rate is to be found, divide the percentage by the base.

Example: $24 is what per cent of $400?
$24÷$400=.06 or 6%

To find the base:

When the percentage and the rate are given and the base is to be found, express the rate as a decimal and divide the percentage by it, or divide the percentage by the rate to find 1% and multiply the quotient by 100 to find 100%.

Example: If a sum of money invested at 6% produces $24, what is the sum invested?
6%=.06 $24÷.06=$400.
OR
$24÷6=$4=1%
100%, the amount,=100×$4=$400.

Per cents of increase:

When the amount and the rate of increase are given and the base is to be found, divide the amount by the sum of the rate and 100% expressed as decimals.

Example: A merchant sold a hat for $8 and thereby gained 33 1/3%. What was the cost of the hat?
33 1/3%=.33 1/3
1.00 plus .33 1/3=1.33 1/3
$8.00÷1.33 1/3=$6.00, the cost.

When the rate is an aliquot part of $1.00, the solution is frequently easier by fractions.
33 1/3%=1/3 1 plus 1/3=4/3
4/3=$8, then 1/3=$2 and 3/3=$6.

Per cents of decrease:

When the difference and the rate are given and it is required to find the base, subtract the rate from 100% and divide the given difference by the difference in per cent expressed as a decimal OR divide the given difference by the difference in per cent to find 1% and then multiply the quotient by 100 to find 100%.

Example: A man sold his automobile for $600 and thereby lost 20%. What was the cost of the automobile?
100%−20%=80%=.80
$600.00÷.80=$750
OR
$600÷80%=$7.50=1%
100%=100×$7.50=$750.

In this case, as in the case of per cents of increase, the work may be simplified by the use of common fractions.

DISCOUNTS

A discount is an amount deducted from a sum owing. Discounts may be trade discounts (sometimes called commercial discounts) or cash discounts (sometimes called time discounts). The amount of a discount is usually indicated by a rate per cent.

A trade or commercial discount is an amount deducted from the list price of an article. Manufacturers and wholesalers publish price lists and catalogs at great expense. To avoid issuing a new catalog with every fluctuation of the market, they

issue discount sheets which show the discounts to which the prices in the catalog are subject. Trade discounts may also vary upon the size of the order, the desirability of the customer, etc. These variations are frequently expressed by two or more discounts called a DISCOUNT SERIES. When two or more discounts are quoted, one denotes a discount off of the list price; another, a discount off of the remainder; another, a discount off of that remainder, etc. It is immaterial in what order the discounts are deducted, as will be found by deducting a series in different order.

A cash or time discount is an allowance made for the payment of the bill in less time than allowed by the terms of the sale. These discounts are expressed upon the invoice in the following form: 5/10, 2/30, n/60 and are read, "five per cent off in ten days, two per cent off in thirty days, net in sixty days".

It will be evident that the amount of the commercial discount is determined by the quotation, while the amount of the cash discount is determined by the time of payment.

The amount of the invoice before any deductions are made is termed the GROSS AMOUNT. The amount of the invoice after deducting the discounts is termed the NET AMOUNT.

To find the net amount when the price is subject to trade discount:

(a) When there is only one discount:

Find the percentage and subtract from the price.

\$48 less 12 1/2% = \$48 × .12 1/2 = \$48 × 1/8 = \$6.
\$48 − \$6 = \$42 the net price.

(b) When the discount is expressed in a series:

\$50 less 25% and 20%
\$50 less 20% = \$40 and \$40 less 25% = \$30, the net amount.

OR

\$50 less 25% = \$37.50 and \$37.50 less 20% = \$30, the net amount. (It is evident that the work is rendered easier by selecting the order in which the discounts are deducted.)

(c) Finding a single rate of discount equivalent to a series of two discounts:

(1) Add the discounts;
(2) Multiply the discounts;
(3) Subtract the product (2) from their sum (1), and the result will be a single discount equivalent to the two. When there are three or more discounts, the first two may be combined as above and then this result and the third combined, etc.

Example: A certain article is sold subject to 25%, 20% and 20% off. The work may be simplified by finding a single discount equivalent to the series: Mentally find an equivalent discount for the first two (25% plus 20% minus 5%, the product, equals 40%). Now mentally combine this equivalent and the last rate of the series (40% plus 20% minus 8% equals 52%, the single equivalent of the series).

Finding the cash discount:

The cash discount is deducted from the invoice after the trade discounts have been deducted. Determine from the date of payment what discount is applicable and find this amount of the invoice.

Example: An invoice dated March 10 for \$2500 is subject to the following terms: 5/10, 2½/30, n/60. Find the net amount to be paid on March 18. Since it is to be paid within ten days, deduct 5%. 5% of \$2500 = \$125. \$2500 − \$125 = \$2375, the net amount.

PROFIT AND LOSS

Profit and Loss is one of the business applications of percentage. In these problems, the base is either the cost or the selling price. The percentage is the profit or loss. The rate is the rate of profit or loss. When the cost is taken as the base:

To find the selling price, add the profit to the cost, or subtract the loss from the cost.

To find the rate of profit or loss, find the profit or loss and then find how many per cent of the cost this is.

To find the cost when the selling price and the rate of profit are given, add the rate of profit to 100% and divide the selling price by this sum expressed as a decimal.

To find the cost when the selling price and the rate of loss are given, subtract the rate of loss from 100% and divide the selling price by the remainder expressed as a decimal.

Buying by the dozen and selling by the unit.

This kind of problem is of frequent occurrence in business.

The following table gives a short method to find the selling price per unit when the purchasing price is by the dozen and the profit is at a certain rate. Other rates of profit may be solved in the same way but the fractions are complicated.

Rate of Profit	Number of places to left decimal point is moved in cost per dozen	Fractional part of the result to be added
20%	1 place	0
25%	1 "	1/24
30%	1 "	1/12
33 1/3%	1 "	1/9
35%	1 "	1/8
40%	1 "	1/6
50%	1 "	1/4
60%	1 "	1/3
80%	1 "	1/2

Example: Hammers are bought for \$18 a dozen. What must be the selling price per hammer to gain 40%? From the table, \$2.10.

Proof: The cost of each hammer is $\frac{\$18}{12}$

The selling price is $1.4 \times \frac{18}{12} = \frac{1.4}{12} \times 18 = \frac{14}{12} \times 1.8 = (1 \text{ plus } 1/6) \times 1.8$.

MARKING GOODS

In large mercantile establishments, it is necessary to have both the price and cost marked upon each article. In order that this information may not come into the hands of those who should not have it, these prices are written in letters or characters. The following are examples of such schemes:

Cost Key
S I L K T H R E A D 3 25
1 2 3 4 5 6 7 8 9 0 L I T
Repeaters X and Y

Selling Price Key
P U R C H A S E N O W
1 2 3 4 5 6 7 8 9 0 Repeater 5.00 H O W

COMMISSION AND BROKERAGE

Use.—A large part of business is carried on through agents, brokers and factors. This is particularly true in the case of insurance, real estate, stocks and bonds, and certain classes of merchandise.

Definitions.—An AGENT, FACTOR, BROKER, or COMMISSION MERCHANT is one who transacts business for the account of another. The person or company for whom the business is transacted is called the PRINCIPAL.

The compensation paid to the agent or broker is called the COMMISSION or BROKERAGE. The commission is usually a certain per cent of the amount involved in the transaction, or a certain amount per unit handled. Commission merchants frequently make an additional charge for assuming some special risk in connection with the transaction; such as the quality of the goods, collection of the accounts, etc.

The goods sent to an agent is called a CONSIGNMENT. Sometimes the sender of the goods calls it a SHIPMENT and the agent calls it a CONSIGNMENT.

The person sending the goods is called the CONSIGNOR or SHIPPER; the one to whom they are sent is called the CONSIGNEE.

The statement rendered to the principal by the agent is called an ACCOUNT SALES in the case of a sale of goods and an ACCOUNT PURCHASE in the case of a purchase. The statements contain an account of the gross amount involved and the expenses and commission.

In the sale of goods, the GROSS PROCEEDS is the total amount received by the agent and the NET PROCEEDS is the amount received less the expenses and commissions. In the purchase of goods, the NET PRICE is the amount the agent actually pays for the goods and the GROSS PRICE is the amount after all expenses and commissions have been added.

Problems in commission and brokerage are merely special applications of percentage as the following comparison of terms will show.

The *sales price*, or the *purchase price*, is the *base* in percentage.

The *rate of commission* is the *rate* in percentage.

The *commission* is the *percentage*.

ACCOUNT SALES

Chicago, Ill., March 18, 1922

Sold for the account of Greenwood & Co.

By C. H. BAIR AND COMPANY

March	8	300 bbl. Flour	\$8.00			\$2400	00
	15	200 bbl. Pastry Flour	9.00			1800	00
		CHARGES					
March	7	Freight and Drayage		\$ 50	25		
	15	Commission 5%		210	00		
	16	Proceeds remitted		3939	75		
				\$4200	00	\$4200	00

ACCOUNT PURCHASE

Baltimore, Md., March 18, 1922

Purchased by **FRANCE AND BARRETT**
Commission Merchants

For the account and risk of Archer and Roe,
York, Pa.

100 boxes Oranges	$6.50	$650 00	
100 boxes Lemons	6.00	600 00	$1250 00
CHARGES			
Freight		$25 50	
Drayage		10 00	
Commission 2%		25 00	60 50
Amount charged to your account			$1310 50

The *gross cost* in the account purchase is the *amount* in *percentage*.

The *net proceeds* in the account sales is the *difference* in percentage.

TO FIND THE COMMISSION when the rate and price are given. This is the same as the problem of finding the percentage when the base and rate are given. Thus, if the selling or buying price is $2000 and the rate of commission is 5% the commission is 5% of $2000 or $100.

TO FIND THE NET PROCEEDS when the selling price and the rate of commission are given. This is the same as the problem of finding the difference when the base and rate are given. Thus, if the selling price is $2000 and the rate of commission is 5%, the net proceeds is $2000 − $100 = $1900.

TO FIND THE GROSS PRICE (the total sales or purchases) when the rate and commission are given. This is the same as the problem of finding the base when the rate and the percentage are given. Thus, if the commission is $100 and the rate is 5%, 1% equals $20 and 100% equals $2000.

TO FIND THE NET PRICE IN BUYING when the gross price and the rate of commission are given. This is the same as the problem of finding the base when the rate and amount are given. $2100 ÷ 105% = $20 or 1%; 100% = $2000.

It will be noticed that the commission is always computed upon the total amount of the sales or purchases.

SIMPLE INTEREST

Use.—Interest is the most common of all the applications of percentage. At one time or another, practically every one needs to figure interest. In business the problem of interest is of frequent occurrence and in the banking business it is in constant use.

Definitions.—INTEREST is the amount paid as compensation for the use of money. A man borrows $100 for a year and at the end of the year he must pay back $106. The extra $6 is paid for the use of the $100 for one year and is called interest.

The PRINCIPAL is the amount on which the interest is paid.

The AMOUNT is the principal plus the interest.

The RATE OF INTEREST is the percentage of the principal which is paid for the use of the principal for one year.

Since the rate of interest is nearly always expressed in terms of one year, the time is an important element in computing interest.

When the time is one year, problems in interest are problems of ordinary percentage, and

(*a*) The principal is the base;

(*b*) The rate of interest is the rate of percentage;

(*c*) The interest is the percentage;

(*d*) The amount is the same in both cases.

When the time is more than one year the interest is the interest for one year multiplied by the number of years. Thus, the interest on $100 for two years is 2 × $6 or $12.

When the time is less than one year the interest is the interest for one year multiplied by the fractional part of a year. Thus, the interest on $100 for six months is ½ of $6, or $3.

The legal and maximum rates of interest in the different states are determined by the laws of the different states. The legal rate of interest is the rate charged when no rate is agreed upon between the parties. The maximum rate is the highest rate allowed by law. A binding contract to pay more than the maximum rate of interest cannot be made. Charging more than the maximum rate of interest is called usury and is penalized in most of the states. The following table shows the legal and maximum rates of interest in the different states:

	Legal rate	Maximum rate
Alabama	8	8
Alaska	8	12
Arizona	6	10
Arkansas	6	10
California	7	any
Colorado	8	any
Connecticut	6	6
Delaware	6	6
District of Columbia	6	10
Florida	8	10
Georgia	7	8
Idaho	7	12

*Corporations may contract to pay any rate of interest and any rate may be charged on call loans of $5000 and upwards.

Kinds of Interest.—The following kinds of interest will be discussed: Ordinary or commercial year interest, accurate interest, and compound interest.

Ordinary or commercial year interest is computed on a 360-day year basis.

Methods of Computing Ordinary Interest.—The most widely used method of computing interest for commercial purposes is what is known as the Bankers' Sixty-Day Method. It is based upon the 360-day year, 12 months of 30 days each, at 6%. Since the rate of interest for one year is 6%, the rate for 60 days or two months is 1% and the interest for six days is .1%. The work can therefore be simplified by working upon the basis of sixty days and aliquot parts of sixty days. Moving the decimal point two places to the left in the principal (which is the same as multiplying the principal by 1%) will give the interest for two months or sixty days; moving the decimal point three places to the left will give the interest for six days, and moving the decimal point one place to the left will give the interest for six hundred days at 6%.

Example 1. Find the interest on $1950 for three months at 6%.

$19 50	interest for two months
9 75	interest for one month (½ of two months)
$29 25	interest for three months (sum of two months and one month)

Example 2. Find the interest on $1250 for five months twenty days at 6%.

$12 50	interest for two months
25 00	interest for four months
6 25	interest for one month
4 166	interest for 20 days
$35 42	interest for five months and twenty days.

Example 3. Find the interest on $1396 for 46 days at 6%.

$ 1 396	interest for 6 days
9 772	interest for 42 days (7 × 6 days)
931	interest for 4 days (2/3 of 6 days)
$10 703	interest for 46 days at 6%.

OR (Working with a different combination of days also constitutes a check on the work).

$13 96	interest for 60 days
6 98	interest for 30 days (½ of 60)
3 49	interest for 15 days (½ of 30)
2326	interest for 1 day (1/30 of 30 days)
$10 7026	interest for 46 days.

Example 4. Find the interest on $4240 for 93 days at 6%.

$42|40 interest for 60 days
21|20 interest for 30 days
2|12 interest for 3 days
$65|72 interest for 93 days

Example 5. Find the interest on $2440 for 1 yr. 7 mo. 6 days at 6%.

$244|00 interest for 20 mo. or 600 days
12|20 interest for 1 month
231|80 interest for 19 months, 1 yr. 7 mo.
2|44 interest for 6 days
$234|24 interest for 1 year 7 months 6 days at 6%.

Interchanging Time and Principal.—It is sometimes possible to shorten the work a great deal by interchanging the time and the principal. This is particularly true where the interest is to be computed upon even hundreds of dollars at an odd number of days; e. g., $2400 for 117 days at 6%. The interest on $2400 for 117 days at 6% is the same as the interest of $117 for 2400 days at 6%.

$24|00 interest on $2400 for 60 days at 6%
48|00 interest on $2400 for 120 days at 6%
1|20 interest on $2400 for 3 days at 6%
$46|80 interest on $2400 for 117 days at 6%

Interchanging principal and time:

($117 for 2400 days at 6%)
$11|70 interest for 600 days
$46|80 interest for 2400 days (4×600 days)

To Find the Interest at Any Rate per Cent.—First find the interest for the given time at 6%. Divide this interest by 6 to find the interest at 1% and then multiply the interest at 1% by the given rate

Example: The interest on $60 for 36 days at 6% is 36c; the interest for the same time at 1% is 6c. The interest at 5% is 5×6c; at 7% it is 7×6c; etc.

The work may be somewhat simplified in the common rates of interest as follows:

Interest at 6% decreased by:
1/8 of itself equals 5¼% interest
1/12 of itself equals 5½% interest
1/6 of itself equals 5% interest
1/4 of itself equals 4½% interest
1/3 of itself equals 4% interest

Interest at 6% divided by:
2 equals the interest at 3%
3 equals the interest at 2%
6 equals the interest at 1%

Interest at 6% increased by:
1/12 of itself equals 6½% interest
1/8 of itself equals 6¾% interest
1/6 of itself equals 7% interest
1/4 of itself equals 7½% interest
1/3 of itself equals 8% interest
1/2 of itself equals 9% interest

Interest at 6% multiplied by 2 equals the interest at 12%.

The work can frequently be simplified and shortened by applying the above increases and decreases to the principal or time, since if either the principal or the time be increased or decreased by any fraction of itself, the interest is increased or decreased by the same fraction. *Example:* Find the interest on $480 for 77 days at 4½%. Since 4½% is ¼ less than 6%, decrease the principal by ¼ of itself and the result is $360. Interchanging principal and time, the problem is the interest on $77 for 360 days at 6%. The interest for 60 days is 77c and for 360 days, 6×77c, or $4.62.

Pointing Off for Rates Other Than 6%.—Pointing off two places in the principal will give the interest at the rates and for the time as follows:

At 1% for one year
2% for six months or 180 days
3% for four months or 120 days
4% for three months or 90 days
4½% for 80 days
5% for 72 days
7½% for 48 days
8% for 45 days
9% for 40 days
10% for 36 days
12% for 30 days

It is not necessary to remember these figures as they can easily be found as follows: 4% is 2/3 of 6%. To earn 1c it will take as many days as 60÷2/3=3/2×60=90.

The Six per Cent Method.—This method is very satisfactory when the tme is one year, or more than one year.

Method:
Multiply the number of years by $0.06
Multiply the number of months by $0.005
Multiply the number of days by $0.000 1/6
Find the sum of these products and multiply the principal by the sum.

Example: Find the interest on $250 for 1 year 8 months 15 days at 6%.

$0.06 interest on $1 for 1 year.
.04 interest on $1 for 8 months.
.0025 interest on $1 for 15 days.
$0.1025 interest on $1 for entire time.
250×$0.1025=$25.63 the required interest.

For rates other than 6% proceed as in the Banker's 60-Day Method.

Calculating Interest by Use of Interest Tables.—In banks and banking houses where a large portion of the work consists of interest computations, tables are employed to lessen the labor, speed up the work, and reduce the probability of error. The following is a sample page of such a table.

INTEREST TABLE AT 6%.

TIME	$1	$2	$3	$4	$5	$6	$7	$8	$9	$10	TIME
1 da.	.00017	.00033	.0005	.00067	.00083	.001	.00117	.00133	.0015	.00167	1 da.

1 mo.	.005	.01	.015	.02	.025	.03	.035	.04	.045	.05	1 mo.
2 mo.	.01	.02	.03	.04	.05	.06	.07	.08	.09	.10	2 mo.
3 mo.	.015	.03	.045	.06	.075	.09	.105	.12	.135	.15	3 mo.
4 mo.	.02	.04	.06	.08	.10	.12	.14	.16	.18	.20	4 mo.
5 mo.	.025	.05	.075	.10	.125	.15	.175	.20	.225	.25	5 mo.
6 mo.	.03	.06	.09	.12	.15	.18	.21	.24	.27	.30	6 mo.
7 mo.	.035	.07	.105	.14	.175	.21	.245	.28	.315	.35	7 mo.
8 mo.	.04	.08	.12	.16	.20	.24	.28	.32	.36	.40	8 mo.
9 mo.	.045	.09	.135	.18	.225	.27	.315	.36	.405	.45	9 mo
10 mo.	.05	.10	.15	.20	.25	.30	.35	40	.45	.50	10 mo.
11 mo.	.055	.11	.165	.22	.275	.33	.385	44	.495	.55	11 mo.
1 yr.	.06	.12	.18	.24	.30	.36	.42	48	.54	.60	1 yr.
2 yr.	.12	.24	.36	.48	.60	.72	.84	.96	1.08	1.20	2 yr.

Example: Find the interest on $7560 for 9 days at 6%.

From the table:
$10.50=interest of $7000 for 9 days
.75=interest on $500 for 9 days
.09=interest on $60 for 9 days
$11.34=interest on $7560 for 9 days.

Accurate or Exact Interest.—Exact interest is based upon a year of 365 days and when the exact number of days between dates is taken. Exact interest is used by the United States Government and sometimes by bankers and city and state governments when the sum involved is very large.

Problems in exact interest can be solved best by the cancellation method using this formula: $\frac{\text{rate}\times\text{days}\times\text{principal}}{365}$ = exact interest. Exact interest may also be found by computing the interest in the usual way for the 360-day year and from the interest so obtained taking 1/73 of itself. Accurate or exact interest may be changed to ordinary interest by adding 1/72 of itself.

The Cancellation Method of Figuring Interest.—Since the interest equals the principal×rate×time, the problem may be solved by expressing the time as a fractional part of a year and using cancellation. This method is sometimes very advantageous. It is applicable to any rate and to either ordinary or accurate interest.

Example: Find the accurate interest on $1850 at 5% for 50 days.

$$\frac{\$1850\times\frac{1}{20}\times\frac{50}{365}}{} = \frac{925}{73} = \$12.67$$

COMPOUND INTEREST.

Compound interest is the interest computed at regular intervals on the sum of the principal and the unpaid interest. Interest may be compounded annually, semi-annually, or quarterly. Interest may be compounded monthly, but this is unusual. Compound interest cannot be collected at law but when it is accepted it does not constitute usury. Compound interest is allowed by savings banks and used by insurance companies in computing premiums. It is also used in computing sinking funds, etc.

Example: Find the compound interest on $100 at 5% for three years compounded annually.

$5.00=interest for the first year
105.00=amount at end of first year—new principal
5.25=interest for the second year
110.25=amount at the end of second year—new principal
5.51=interest for the third year
115.76=amount at the end of the third year
$115.76−$100=$15.76 the compound interest

Business institutions having compound interest to compute use a table of which the following is a sample page:

COMPOUND INTEREST TABLE.

Showing the amount of $1.00 for any number of periods up to 25, at the given rates.

No. Period	Rate Per Period									
	1%	1½%	2%	2½%	3%	3½%	4%	4½%	5%	6%
1	1.010000	1.005000	1.020000	1.025000	1.030000	1.035000	1.040000	1.045000	1.050000	1.060000

10	1.104622	1.160541	1.218994	1.280085	1.343916	1.410599	1.480244	1.552969	1.628895	1.790848
11	1.115668	1.177949	1.243374	1.312087	1.384234	1.459970	1.539454	1.622853	1.710339	1.898299
12	1.126825	1.195618	1.268242	1.344889	1.425761	1.511069	1.601032	1.695881	1.795856	2.012197
13	1.138093	1.213552	1.293607	1.378511	1.468534	1.563956	1.665074	1.772196	1.885649	2.132928
14	1.149474	1.231756	1.319479	1.412974	1.512590	1.618695	1.731676	1.851945	1.979932	2.260904
15	1.160969	1.250232	1.345868	1.448298	1.557967	1.675349	1.800944	1.935282	2.078928	2.396558
16	1.172579	1.268986	1.372786	1.484506	1.604706	1.733986	1.872981	2.022370	2.182875	2.540352
17	1.184304	1.288020	1.400241	1.521618	1.652848	1.794676	1.947901	2.113377	2.292018	2.692773
18	1.196148	1.307341	1.428246	1.559659	1.702433	1.857489	2.025817	2.208479	2.406619	2.854339
19	1.208109	1.326951	1.456811	1.598650	1.753506	1.922501	2.106849	2.307860	2.526950	3.025600
20	1.220190	1.346855	1.485947	1.638616	1.806111	1.989789	2.191123	2.411714	2.653298	3.207136
21	1.232392	1.367058	1.515666	1.679582	1.860295	2.059431	2.278768	2.520241	2.785963	3.399564
22	1.244716	1.387564	1.545980	1.721571	1.916103	2.131512	2.369919	2.633652	2.925261	3.603537
23	1.257163	1.408377	1.576899	1.764611	1.973587	2.206114	2.464716	2.752166	3.071524	3.819750
24	1.269735	1.429503	1.608437	1.808726	2.032794	2.283328	2.563304	2.876014	3.225100	4.048935
25	1.282432	1.450945	1.640606	1.853944	2.093778	2.363245	2.665836	3.005434	3.386355	4.291871

Solving the preceding example by the table, we find that $1 will amount to $1.157625 in three years. $100 will therefore amount to $115.76 and the compound interest is $15.76.

Sinking Funds.—A sinking fund is a fund set aside out of assets at regular intervals and accumulating interest for the purpose of paying off bonds or other obligations, replacing machinery, buildings or other assets. A state or city has an issue of bonds which mature in a certain time. It wishes to accumulate a fund by setting aside a certain amount periodically in order that it may have the money to pay off the bonds when they mature. A business wishes to accumulate a fund for the purpose of replacing dynamos or other machinery. Such funds are called sinking funds.

In the following table is shown the sum to which $1, paid at the beginning of each year, will increase at certain rates of compound interest in any number of years not exceeding twenty.

Yr.	2%	4%	4½%
1	1.020000	1.040000	1.045000
2	2.060400	2.121600	2.137025
3	3.121608	3.246464	3.278191
4	4.204040	4.416322	4.470709
5	5.308120	5.632975	5.716891
6	6.434283	6.898294	7.019151
7	7.582969	8.214226	8.380013
8	8.754628	9.582795	9.802114
9	9.949721	11.006107	11.288209
10	11.168715	12.486351	12.841178
11	12.412089	14.025805	14.464031
12	13.680331	15.626837	16.159913
13	14.973938	17.291911	17.932109
14	16.293416	19.023587	19.784054
15	17.639285	20.824531	21.719336
16	19.012070	22.697512	23.741706
17	20.412312	24.645412	25.855083
18	21.840558	26.671229	28.063562
19	23.297369	28.778078	30.371432
20	24.783317	30.969201	32.783136

To Find the Rate of Interest.—It frequently happens that a man investing money in a venture and making a certain profit, wishes to know what rate of interest he has realized on the transaction. *Example:* A man invested $1800 and in six months he had closed out the transaction and taken a profit of $108. What rate of interest did he make on the investment? Since six months are one-half of a year, the profit for a year at the same rate would have been $216 and this is 12% on $1800. For methods of finding this rate refer to method of finding rate of percentage.

To Find the Time When the Principal, Rate and Interest Are Given.—Divide the interest by the interest for one year. This problem does not occur frequently in business.

To Find the Principal When the Rate, Time and Amount Are Given.—Find the amount of $1 for the given time and rate and divide the given amount by it.

Example: Find the principal when the amount in three months at 6% is $2436.00. The interest on $1 for three months at 6% is $0.015 and the amount is $1.015. $2436.00 ÷ $1.015 = $2400.00, the principal.

A certificate of deposit is a negotiable instrument in which a bank certifies that the person named in the instrument has deposited the sum of money named. This money is payable to the person named or his order on the surrender of the certificate of deposit properly indorsed. The money so deposited is not subject to checks.

When a person has a negotiable instrument in his possession he is called the HOLDER. He may transfer it to another by delivery if it is made payable to bearer. If it is drawn to the order of the payee, he may transfer it by INDORSEMENT. An indorsement is any writing on the back of the instrument. Indorsements for the purpose of transferring the instrument are BLANK INDORSEMENTS, FULL OR SPECIAL INDORSEMENTS, or QUALIFIED INDORSEMENTS.

A Blank Indorsement is simply the signature of the holder.

A Full Indorsement is one which names the person to whom it is to be paid; e. g., "Pay to the order of J. G. Smith".

A Qualified Indorsement is one which limits the liability of the indorser by inserting the words, "Without Recourse".

In case of partial payments on a note, a record of the payment is indorsed on the note; e. g., Received on within note:

Jan. 6, 1922.....$500.00
May 15, 1922..... 300.00
June 7, 1922..... 200.00

A negotiable instrument which is not paid or accepted (as the case may be) when presented, is said to be DISHONORED.

Protest is a formal declaration made by a notary public certifying to the presentment, demand and dishonor of a negotiable instrument. It is used for the purpose of proving the proper handling of the instrument to protect the interests of the indorsers. It is required by law upon drafts drawn in one state and payable in another.

Days of Grace are three extra days beyond the due date allowed for the payment of negotiable instruments. Days of Grace have been abolished in all except a few of the states.

Bank Discount is a deduction made from the amount due at maturity on notes and drafts because they are cashed before maturity. It is the interest on the amount due at maturity and collected in advance for the time from the date of discount to the date of maturity.

The Term of Discount is the time from the date of discount to the maturity of the instrument. Banks always count the exact number of days.

The proceeds is the difference between the amount due at maturity and the discount on the instrument.

MATURITY TABLE

1	Jan.	−1	13
2	Feb.	+2	14
3	Mar.	−1	15
4	April		16
5	May	−1	17
6	June		18
7	July	−1	19
8	Aug.	−1	20
9	Sept.		21
10	Oct.	−1	22
11	Nov.		23
12	Dec.	−1	24

Bankers, and others having the counting of terms of discount to do, make use of a table like this.

To Find the Date of Maturity and Term of Discount.

Example: Find the maturity of a note dated June 10 and payable (a) three months after date, (b) ten months after date, (c) ninety days after date.

(a) Referring to the table, notice that June is the sixth month. Add 3 to the 6 months and the result is 9. The 9th month is Sept. (from table) and the note is due Sept. 10.

(b) Add 6 and 10 and the result is 16. The note is due in the 16th month, which, (from the table) is April. The note is therefore due on April 10.

TABLE OF TIME

FROM ANY DAY OF	TO THE SAME DAY OF THE NEXT											
	Jan.	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
JANUARY	365	31	59	90	120	151	181	212	243	273	304	334
FEBRUARY	334	365	28	59	89	120	150	181	212	242	273	303
MARCH	306	337	365	31	61	92	122	153	184	214	245	275
APRIL	275	306	334	365	30	61	91	122	153	183	214	244
MAY	245	276	304	335	365	31	61	92	123	153	184	214
JUNE	214	245	273	304	334	365	30	61	92	122	153	183
JULY	184	215	243	274	304	335	365	31	62	92	123	153
AUGUST	153	184	212	243	273	304	334	365	31	61	92	122
SEPTEMBER	122	153	181	212	242	273	303	334	365	30	61	91
OCTOBER	92	123	151	182	212	243	273	304	335	365	31	61
NOVEMBER	61	92	120	151	181	212	242	273	304	334	365	30
DECEMBER	31	62	90	121	151	182	212	243	274	304	335	365

(c) Three months added to the 6th month (June) equals 9. The note is due in the 9th month, which is September. Since the note is payable in ninety days, exact time must be found. Notice in the table that one day must be subtracted for each of July and August. 10−2=8. The note is therefore due on September 8.

With a little practice it will be unnecessary to use such a table. Counting ahead the number of months or days will establish the due date.

The Term of Discount is found by counting the exact time in days from the date of discount to the date of maturity. *Example:* In a note due on July 14 and discounted on May 3, the term of discount is 72 days. This may be found as follows:

28 days remaining in May
30 days in June
14 days in July
72 days is the term of discount.

Bankers frequently use a table like the foregoing for the purpose of finding the exact number of days between the two dates:

The above example would be solved with the table by looking in the column marked "July" on a line with May. The number of days given there is 61, which indicates that there are 61 days from any date in May to the *same* date in July. From May 3 to July 3 there are 61 days; from July 3 to July 14, there are 11 days; the total is 72 days, and this is the term of discount.

To Find the Bank Discount of a Note or Draft, find the interest on the face of the note for the term of discount. This is a problem in simple interest and is explained under that subject.

To Find the Proceeds of a Discounted Note or Draft, subtract the bank discount from the face of the note.

To Find the Proceeds of an Interest-Bearing Note or Draft, find the interest for the time of the note at the rate of interest stated in the note and add this to the face of the note to find the amount due at maturity. Find the interest for the term of discount on the value of the note at maturity and subtract this interest from the value at maturity.

Example: A 90-day note for $2000 bearing interest at 5% was discounted at 6% 45 days before maturity. Find the proceeds.

Solution:

$2000.00	Face of note.
25.00	Interest on note
$2025.00	Amount due at maturity
15.19	Discount—Interest for 45 days at 6% on $2025
$2009.81	Proceeds of note.

Collection and Exchange Charges.—Banks sometimes make a small charge for collection and exchange on notes and drafts payable out of town. The rate of exchange and the charges for collection are usually expressed in a fraction of a per cent. These charges are computed upon the value of the instrument at maturity; i. e., on the face of a non-interest-bearing note and on the amount of an interest-bearing note.

When an interest-bearing note is discounted on the day it is made and the rates of discount are the same, the bank will usually give credit for the face of the note. When an interest-bearing note is discounted after the date of issue and the rate of interest is the same as the rate of discount, it is customary among some bankers to give the customer credit for the face of the note plus the interest to the date of discount.

BANK DISCOUNT

Negotiable Instruments.—A negotiable instrument is a written evidence of debt which may be transferred from one person to another by indorsement and delivery or by delivery alone. The most common negotiable instruments are checks, drafts, notes, and bonds.

A check is a bill of exchange drawn on a bank and payable on demand.

A Check

No. 126 ATLANTA, GEORGIA, March 25, 1943

THE MERCHANTS BANK.

Pay to the order of John P. Harrison $45.25

Forty-five and 25/100 DOLLARS

In College Currency

J. E. Hall

A draft (or bill of exchange) is an order drawn by one person (called the drawer) directing another (called the drawee) to pay a third (called the payee) or to bearer a certain sum of money at a certain time. Drafts may be made payable at sight, at a certain time after sight, or at a certain time after date.

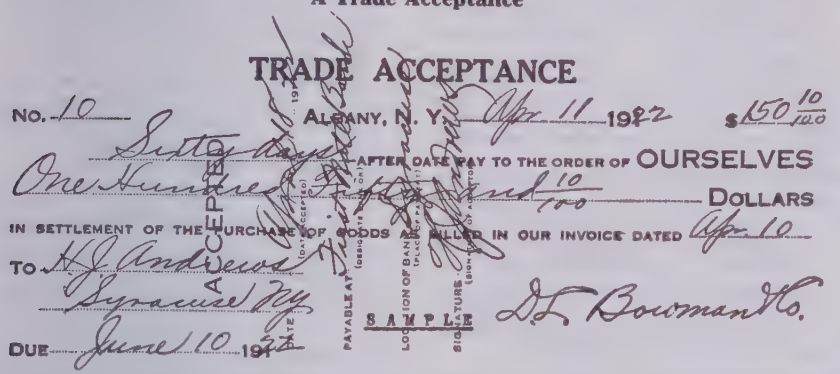
H. D Sanderson

To Wildman & Colvin

No 2 146 Main Street Richmond, Va.



Before a draft can be enforced against the drawee, he must accept it. He does this by writing across the face (usually in different colored ink) "Accepted", the date and his signature. The instrument is then called an acceptance.

An Acceptance

A trade acceptance is an acceptance given at the time and for the amount of a purchase of merchandise.

A Trade Acceptance

A bank draft (sometimes called a New York draft or a Chicago draft from the name of the city upon which it is drawn) is a draft drawn by one bank upon another bank.

A Promissory Note is an unconditional written promise to pay a sum certain in money to designated person or his order or to bearer on demand or at a fixed or determinable future time.

The one who signs a promissory note is called the maker. The one in whose favor it is made is called the payee.

A promissory note may be several or joint or joint and several. An ordinary note signed by one or two persons is a several note. A note reading "we jointly promise" is a joint note and one reading "we jointly and severally" is a joint and several note.

A Promissory Note

Find the Face of a Discounted Note.—It sometimes happens that it is desired to discount a note so that the proceeds will be a certain amount. *Example:* I wish to borrow $1990 for 30 days. What must be the face of my note discounted at bank at 6% to obtain the amount?

The bank discount on $1.00 for the time is $0.005.

The proceeds of $1.00 are $0.995.

$1990 (the proceeds required) ÷ $0.995 = $2000, the face of the note.

Proof: The discount on $2000 for 30 days is $10.00. $2000.00 − $10.00 = $1990.

Note.—It would be better to give the bank an interest-bearing note for the amount required and pay the interest when the note becomes due. This can also be done by giving a demand note and paying it in thirty days.

Present Worth and True Discount.—Similiar to the problem of finding the face of a note to produce a given proceeds is the problem of present worth. The PRESENT WORTH of a debt is a sum which, if put at interest, will amount to the value of the debt at maturity.

Example: A man owes a note for $2525 due in two months with interest. What is the present worth and the true discount on this note?

Solution: The interest on $1.00 for two months is $0.01

$1.00 will, in two months, amount to $1.01.

$2525 ÷ $1.01 = $2500, the present worth of the note.

The True Discount is the difference between the present worth and the amount of the note at maturity. In the above example it is $2525 − $2500 = $25.

Partial Payments.—When payments are made from time to time on a note or debt, these payments are called PARTIAL PAYMENTS.

Method of computing partial payments according to the United States Rule (so called because it has been adopted by the U. S. Supreme Court).

1. Find the amount of the note up to the date of the first payment. If this payment is sufficient to cover the interest up to that date, deduct it from the amount. The result is the new principal.

2. Using this new principal, find the amount of the note up to the date of the second payment and deduct payment as before.

3. Proceed in this manner until the final date is reached.

4. If a payment is not sufficient to cover the interest for the period next preceding, no deduction is made, but the payment is added to the next payment.

Example: On a note for $1200 dated Jan. 1 and bearing interest at 6%, payments were made as follows: Mar. 1, $212; July 1, $15; Sept. 1, $515. What was the amount due on Dec. 1?

Solution:

Face of note		$1200.00
Interest from Jan. 1 to Mar. 1 (2 mo.)		12.00
Amount due Mar. 1		$1212.00
Payment on Mar. 1		212.00
Balance due, new principal Mar. 1		$1000.00
Interest from Mar. 1 to July 1 (4 mo.) $20.00 (Interest greater than payment)		
Interest from July 1 to Sept. 1 (2 mo.)	$10.00	$30.00
Amount due Sept. 1		$1030.00
Payments July 1 and Sept. 1		530.00
Balance due, new principal Sept. 1		$500.00
Interest, Sept. 1 to Dec. 1 (3mo.)		7.50
Amount due Dec. 1		$507.50

Merchants' Rule.—This rule is frequently used by business men and sometimes by banks to settle short time notes or indebtedness.

(1) Find the amount of the principal to the date of final settlement.

(2) Find the amount of each payment to the date of final settlement.

(3) From the sum in (1) subtract the sum of (2). The remainder is the amount due.

Example: A note for $3000 bearing interest at 6% and dated March 1 was paid as follows: May 1, $1000.00; July 1, $500.00; Sept. 1, the balance was paid. What amount was required to settle on Sept. 1?

Solution:

Original principal		$3000.00
Interest March 1 to Sept. 1 (6 mos.)		90.00
Amount of note on Sept. 1		$3090.00
Payment May 1	$1000.00	
Interest May 1 to Sept. 1	20.00	
Amount of May 1 payment	$1020.00	
Payment July 1	$500.00	
Interest July 1 to Sept. 1	5.00	
Amount of July 1 payment	$505.00	
Total amount of payments		$1525.00
Balance due Sept. 1		$1565.00

TAXATION

A tax is a sum levied for the support of government or for other public purposes.

A DIRECT TAX is one levied on a person, his property or his business. Direct taxes are poll taxes, property taxes, licenses, and income taxes.

A POLL TAX is a tax on a person.

A TAX ON PROPERTY is called a PROPERTY TAX.

A tax on a business is called a LICENSE FEE.

AN INCOME TAX is a tax on a person's income.

INDIRECT TAXES are levied on imports, tobacco and other articles consumed in the country.

Determining the Rate of Taxation.—When it is determined what sum must be raised by property tax for the expenses of government, this amount is divided by the assessed valuation of all the taxable property in the governmental division. Assessors appraise the property in the city or county and in this way find the assessed valuation of the property of each person and the total assessed valuation for the city or county. The division of the sum to be raised by the total assessed valuation gives the tax rate and it is usually expressed in a certain number of mills per dollar, a certain number of cents per hundred dollars, or a certain per cent.

Example: The total assessed valuation is $2,500,000 and the total amount to be raised is $12,500. Dividing $12,500 by $2,500,000, the tax rate is found to be .5%.

To Find the Tax multiply the assessed valuation by that tax rate.

Example: Johnson's property is assessed at $2000. The tax rate is 1.4%. His tax amounts to 1.4%×$2000 or $28.

At the office where the taxes for each person are computed, a tax table shows the amount of tax at the required rate on every dollar from $10 to $100.

Income Tax.—The United States Government and some of the state governments now impose a tax on certain incomes. For the state taxes consult the laws of the several states. Wisconsin with the state income tax act of 1911, was a pioneer in this movement. Most of the states using income taxation have introduced their systems since 1911. In a general way the state income tax laws follow those of the federal government.

Federal Income Taxes.—The federal revenue act of 1936 provides a tax on incomes above certain levels. The normal tax on individuals now is 4% of the amount of the net income in excess of the credits against net income.

A single person is allowed a personal exemption of $1,000. A married person living with wife or husband is allowed a personal exemption of $2,500. A husband and wife living together receive but one personal exemption. An exemption of $400 for each dependent is granted, such dependent being other than husband or wife and dependent upon and receiving his chief support from the taxpayer if such dependent is under eighteen years of age or is incapable of self-support because mentally or physically defective.

Deductions for credits allowed individuals and corporations are too numerous and too much subject to changes to be listed here. The reader is referred to the offices of the collectors of internal revenue for complete current information.

Surtaxes.—A surtax is levied on the "surtax net income," i.e., the amount of the net income in excess of the credits against net income. There is no tax on a surtax net income of $4,000 or less. The surtax on surtax net incomes in excess of $4,000 and not in excess of $6,000 is 4% of such excess. Above $16,000 the surtaxes upon net incomes and the per cent in addition of net incomes in excess of the first sum named but not in excess of the second sum are stated in the table which follows, at the top of the first column on page 831.

The following is a COLLATERAL NOTE

$1,500.00 SAMPLE Albany, N. Y., Feb. 5, 1922.

**** ON DEMAND **** for value received, the undersigned jointly and severally promise to pay to the order of **THE NEW YORK STATE NATIONAL BANK OF ALBANY,** (hereinafter called the Bank), at its Banking Office in Albany, N. Y., the sum of **** Fifteen Hundred and no-100 **** Dollars in United States gold coin or its equivalent, with interest from date hereof, at the rate of .....per cent. per annum, having deposited with the Bank, as collateral security for the payment of this note, or any note given in extension or renewal thereof, as well as for the payment of any other obligation or liability, direct or contingent, of the undersigned, or any of them, to the Bank, due or to become due, whether now existing or hereafter arising, the following property, viz:

25 shares New York Central Stock

of a market value estimated by the undersigned at $2,000.00; and the undersigned agree to deliver to the Bank additional securities, or to make payments on account to its satisfaction, should the market value of the said securities, as a whole, suffer any decline. The undersigned hereby give to the Bank a lien for the amount of all such obligations and liabilities upon all the property or securities now or at any time hereafter given unto or left in the possession of the Bank by the undersigned, whether for the express purpose of being used by the Bank as collateral security, or for any other or different purpose, and also upon any balance of the deposit account of the undersigned, or any of them, with the Bank. The undersigned hereby jointly and severally agree that all assignments or other dispositions of any of said collateral securities by the undersigned, or any of them, are and shall be subject and subordinate to the Bank's lien thereon for the payment of this or of any other note or claim hereby secured or of any renewal or extension of any

On the non-performance of this promise, or upon the non-payment of any of the liabilities above mentioned or in case of the failure of the undersigned to meet at maturity any liability of the undersigned, either to said Bank or to any other party, or upon the failure of the undersigned forthwith, with or without notice, to furnish satisfactory securities in case of any decline in market value as aforesaid, or upon the declared insolvency or failure in business of, or appointment of a receiver for, or commission of any act of bankruptcy or commencement of any bankruptcy proceeding by or against the undersigned, or the entry of any judgment against the undersigned, or in case of any such default, insolvency, appointment of a receiver, bankruptcy proceedings or judgment by or against any endorser or guarantor of this note, all liabilities of the undersigned to said Bank including this note, shall, at the option of said Bank, immediately mature and become forthwith due and payable without demand or notice, and full power and authority are hereby given the said Bank to sell, assign, transfer and deliver the whole of said securities, or any part thereof or any substitutes therefor or any additions thereto or any other securities or property now or hereafter given unto or left in the possession of the said Bank by the undersigned, for safe keeping or otherwise at public or private sale or at the New York Stock Exchange, or at any other Exchange or Broker's Board, at such prices as it may deem best, and either for cash or on credit or for future delivery, at the option of said Bank, or of its President, or Cashier, without either demand, advertisement or notice of any kind, which are hereby expressly waived and if such collateral is disposed of at private sale, the said Bank shall be relieved from all liability or claim for inadequacy of price. At such sale, the said Bank may itself purchase the whole or any part of the property sold, free from any right of redemption on the part of the undersigned, which is hereby waived and released. In case of sale for any cause, after deducting all costs or expenses of any kind for collection, sale or delivery, including all charges for legal services arising from or incidental to the sale, realization or collection of any of such collateral, security, substitutions or additions, or of any of said demands, including this note, the said Bank may apply the residue of the proceeds of the sale or sales so made, to pay one or more or any or all of the said liabilities to the said Bank, as it or its President or Cashier shall deem proper whether then due or not due, making proper rebate for interest on liabilities not then due, returning the overplus, if any, to the undersigned, who agree to be and remain liable to, and to pay the said Bank for any deficiency arising upon such sale or sales, and if any compromise or settlement is made between the said Bank and the undersigned, or between the said Bank and the guarantors or endorsers hereof, or if payment is made to the said Bank by the undersigned, or by the guarantors or endorsers hereof, of any claim of the said Bank for which the undersigned shall be liable, without the sale of any such securities as aforesaid, then the undersigned agree to pay to the said Bank, all costs or expenses including charges for legal services as aforesaid, incurred by said Bank up to the time of such compromise, settlement or payment. The undersigned do hereby authorize and empower the said Bank at its option, at any time to appropriate and apply to the payment and extinguishment of this or any of the above named obligations or liabilities, including interest, costs and expenses, whether now existing or hereafter contracted, any or all moneys and securities now or hereafter in the hands of the said Bank, on deposit or otherwise, to the credit of or belonging to the undersigned, whether the said obligations or liabilities are then due or not due. It is also agreed that the provisions, agreements, terms and conditions hereof shall apply to, and govern any and all notes given in extension or renewal of this note.

The above described property may from time to time, by mutual consent, be exchanged for other property, which shall be held by said Bank subject to all the terms of this note. Upon the transfer of this note the collateral held therefor at the time of transfer or any part thereof, may be delivered to the transferee, who shall thereupon become vested with all the rights and powers above given to said Bank in respect thereto, and the said Bank shall thereafter be forever relieved and fully discharged from any liability or responsibility in the matter.

It is also further agreed that any moneys or other property at any time in possession of said Bank, belonging to the maker, any guarantor or endorser of this note, and any deposits, balance of deposits, or any sums at any time credited by or due from said Bank to any such parties, may at all times, at the option of the said Bank, be held and treated as collateral security for the payment of this note or any other liability of such maker, guarantor or endorser to the said Bank, whether due or not due, and said Bank may at any time, at its option, set off the amount due or to become due hereon, against any claim of any of said parties against said Bank. No delay on the part of the holder hereof in exercising any rights hereunder shall operate as a waiver of such rights.

SAMPLE

L. T. RICHARDS

SURTAX TABLE (Revenue Act of 1936)

Net Income	Surtax and Per Cent
$6,000 to $8,000	$80 and 5%
$8,000 to $10,000	$180 and 6%

$1,000,000 to $2,000,000	$641,000 and 73%
$2,000,000 to $5,000,000	$1,371,000 and 74%
$5,000,000 or more	$3,591,000 and 75%

Tax on Corporations.—Corporations pay normal taxes ranging from 8 to 15 per cent of their normal-tax net incomes plus surtaxes too complicated to describe here.

Miscellaneous Taxes.—Other federal income taxes include the following:

(1) *Estate Tax.*—This tax ranges from 2 per cent of the amount of the net taxable estate not over $10,000 up to 70 per cent of the amount by which the net estate exceeds $50,000,000.

(2) *Tax on Admissions and Dues.*—With certain minimum exemptions, this tax is levied on admissions to places of amusement, contests and so forth, and on club dues.

(3) *Tobacco Taxes* are levied on tobacco products, including cigars, cigarettes, tobacco and snuff.

(4) *Narcotic Taxes.*—Importers, manufacturers, compounders, and wholesale and retail dealers are taxed.

(5) *Liquor Taxes* are levied on alcoholic beverages, including still wine and distilled spirits.

(6) *A Documentary Stamp Tax* is levied on sales and transfers of stocks.

INSURANCE

Insurance is an agreement by one party (called the insurer) for a consideration (called the premium) to indemnify another party (called the insured) against losses arising from certain causes (called the risk).

The INSURANCE POLICY is the written or printed contract containing the agreement between the parties.

Property Insurance.—A VALUED or CLOSED policy agrees to pay a specified amount in case a certain loss is sustained.

An OPEN POLICY provides for an undetermined amount, depending upon the quantity of goods insured at the time of the damage. This policy is used where goods are being deposited and withdrawn from the store or warehouse.

Rate of premium. The premium in property insurance is usually stated at a certain per cent of the amount insured. Rates are usually quoted for a year. Lower rates are charged for long periods and higher rates (known as short term rates) are charged for short terms.

The ORDINARY POLICY is one in which the amount to be paid in case of loss is specified; i. e. the amount of the loss will be paid if it does not exceed the sum stated in the policy.

The AVERAGE CLAUSE provides that where one policy covers several different pieces of property and one of the properties is damaged, the company will pay only that proportion of insurance which the insurance on that property bears to the whole insurance.

The 80% or CO-INSURANCE CLAUSE. Under this clause the insured agrees that he will keep his property insured for a given percentage of its value (80% in New York is the usual percentage) and if he fails to do this, the company will pay only that percentage of the loss which the insured bears to the agreed percentage of the value of the property.

Example: The value of a property is $10,000 and it is insured under the 80% clause but the insured takes out only $4,000 on the property. The property is damaged to the extent of $2000. The company will pay only $\frac{4000}{8000}$ or ½ of the loss.

The PRO RATA CLAUSE is used where there is more than one policy upon the same property. Each company is required to pay the proportion of the loss which its policy bears to the total amount of insurance carried on the property.

Example: A man has his building insured for $5000 in X company, for $10,000 in Y company, and for $15,000 in Z company. The property is damaged by fire to the extent of $6000.

Solution: The total amount of insurance is $30,000.

X Company must pay $\frac{5000}{30000}$ or 1/6 of the loss =	$1000
Y Company must pay $\frac{10000}{30000}$ or 1/3 of the loss =	2000
Z Company must pay $\frac{15000}{30000}$ or 1/2 of the loss =	3000
Total	$6000

The ARITHMETIC PROBLEMS in insurance are simply an application of percentage.

The amount of the insurance is the base in percentage.

The rate of insurance is the rate in percentage.

The premium in insurance is the percentage.

Example: Goods valued at $3000 are insured at the rate of 50c per hundred. The premium for one year is $15.

Life Insurance is a contract in which the insurer, for a consideration called the premium, agrees to pay a specified sum of money upon proof of the death of the insured or at some fixed time.

A STRAIGHT LIFE POLICY is one in which the premiums are paid during the life of the insured and the insurance is paid upon the death of the insured.

A TERM POLICY is one in which the insurance is paid if the insured dies within a fixed period.

An ENDOWMENT POLICY is one in which the insurance is paid at a fixed date, or, if the insured dies before that date, at the death of the insured.

Some policies provide for the payment of the premium for a given number of years and a continuation of the policy after these payments have been made. These policies are named by the number of annual payments as, Twenty Payment Life Policy.

The beneficiary is the person indicated in the policy to receive the payment upon the death of the insured.

EXCHANGE

The system of settling debts between parties residing in different places without sending the actual cash is called EXCHANGE.

DOMESTIC EXCHANGE is the system of settling debts between persons in the same country.

FOREIGN EXCHANGE is the exchange between persons of different countries.

The instruments of exchange are personal checks, bank drafts, commercial drafts, postal money orders, express money orders and telegraphic money orders. The forms of checks, bank drafts and commercial drafts are given under Bank Discount. The form and rates of money orders can be had at post offices, express offices and telegraph offices.

Domestic Exchange. To Find the Cost of a Draft.—

Example: Find the cost of a draft on St. Louis for $400 when exchange is at 1/8% premium.

Solution:

Face of Draft	$400.00
Exchange 1/8% of face	.50
Cost of draft	$400.50

If exchange is at a discount, subtract the exchange from the face of the draft.

To Find the Proceeds of a Draft.—

Solution: Find the proceeds of a draft of $2400, exchange being 1/4%.

Solution: 1/4% of $2400 is $6.00. $2400 −$6.00 = $2394.00.

Foreign Exchange.—Bills of exchange on foreign countries are usually drawn in sets of two or three, called "First and Second of Exchange." These are duplicates and are sent by different mails, but the payment of one cancels the other.

The rates of exchange depend upon the variation of the balances due to or from the different countries. The World War caused great disturbances in exchange rates. The exchange rates used in examples here are the rates that obtain when exchange is in a normal condition. The most important exchange rates are quoted as follows:

Sterling	£1	= $4.8665
French	$1	= F. 5.18
German	M.4	= $.95

A Letter of Credit is a request issued by a bank and addressed to their correspondents in all parts of the world asking them to pay the owner of the letter sums of money up to the amount named in the letter.

To Find the Cost of a Bill of Exchange.—

Example 1. Find the cost of a bill of exchange on Liverpool for £275 15s. 3d. sterling, exchange being quoted at $4.86¼.

£275 15s. 3d. = £275.7625

$4.86¼ × 275.7625 = $1340.90

Explanation: £275 15s. 3d. is equivalent to £275.7625. As £1 sterling is quoted at $4.86¼, £275.7625 will be worth 275.7625 times $4.86¼ = $1340.90.

Example 2. What is the cost of a bill of exchange on Paris for 1449 francs, when exchange is quoted at 5.17½?

1449 ÷ 5.17½ = $280.00.

Explanation: As 5.17½ francs are worth $1, 1449, francs are worth as many dollars as 5.17½ is contained in 1449, or $280.

To Find the Proceeds of a Bill of Exchange.—

Example: Find the proceeds of a bill of exchange for F.4200 at 5.17½−1/32.*

Solution:

F.4200 ÷ F.517½ = 811.59

$811.59 = proceeds at 5.17½

1/32% of $811.59 = 25c

$811.59 − $.25 = $811.34, the proceeds.

*A certain small amount of change in the rate is called a point. When a large amount is to be transferred, the rate is sometimes given in this form.

STOCKS AND BONDS

A corporation is an artificial person created by law and endowed by it with many of the powers of an individual.

The capital of a corporation is divided into a number of shares called the capital stock. This stock may be either preferred or common stock. Preferred stock receives its share of profits first and may have other preferences over the common stock.

Dividends are declared out of the profits of the corporation. The dividend is usually a certain number of dollars per share or a certain per cent of the par value of the stock.

The par value of stock is the value stated in the stock certificate, which the shareholder holds.

The market value of the stock is determined by the price at which the stock can be sold. This price may be above or below par.

Shares of stock are bought and sold through stock brokers who charge a certain percentage, usually 1/8 % of the par value.

To Find the Income From Shares When the Rate Is Known.—

Example: What will be the yearly income from 300 shares of stock which pays 6%.

Solution: 6% means $6 per share of a par value of $100. Hence the income will be $1800.

To Find the Cost of Stock.—

Example: Find the cost of 200 shares at 98½.

Solution: If one share costs $98½, 200 will cost 200 × $98½ = $19,700.

Brokerage.—If stock is bought through a broker (as it usually is), his fee, which is usually 1/8%, must be added to the cost. If brokerage were charged on the above, the cost per share would be $98 5/8. If stock is sold through a broker, the brokerage must be subtracted from the price received per share.

To Find the Proceeds From Sale of Stock.

Example: Find the proceeds of 72 shares sold at 91 1/8 less brokerage 1/8%.

Solution: $91 1/8 less $1/8 = $91 per share, 72 shares will yield 72 × $91 = $6552.

To Find the Rate of Profit on an Investment in Stocks.—

Example: What is the rate of income on an investment in 6% shares costing 120.

Solution: The yield is $6 on an investment of 120. $6.00 ÷ 120 = 5 = the per cent of profit.

To Find the Price per Share Which Will Yield a Given Rate on the Investment.

Example: What must be paid for a 6% stock to yield 5% on the investment?

Solution: $6.00 is 5% of what number. $6 ÷ .05 = $120.

Bonds are long time notes of the national and state governments, cities, counties, and private corporations. A bond bears interest at a specified rate of interest.

A registered bond is one in which the name of the owner is recorded on the books of the issuing corporation.

Coupon bonds have coupons attached which may be clipped off and collected as the interest becomes due. There is one coupon for each interest period.

Bonds are designated by the name of the issues, date of maturity, and the rate of interest. U. S. 4's 1925 means United States bonds maturing in 1925 and bearing 4% interest.

The ordinary ARITHMETICAL PROBLEMS of bonds are the same as those discussed under stocks.

PARTNERSHIP

A Partnership is a contract relation existing between two or more competent parties, uniting their capital, labor, or skill, in some lawful enterprise, agreeing to share the gains, or bear the losses, in certain proportions.

The persons forming a partnership are called Partners or Copartners. Collectively, they are called a Company, House, or Firm.

Partners may be classified, as follows: Real or General, Nominal, Dormant, and Special or Limited.

A Real or General Partner is one who is known to the public as a partner, takes an active part in the management of the business, and is personally liable for all the firm's debts.

A Nominal Partner is one who allows his name to be associated with the partnership, but invests nothing. He is liable to innocent third parties only.

A Dormant Partner is one who makes an investment, but who conceals his identity as a partner from the public. He becomes liable for firm debts when his identity is discovered.

A Special or Limited Partner is one who makes a cash investment, but takes no active part in the management. He is not personally liable for an amount greater than that mentioned in the partnership agreement.

A Partnership Agreement is a contract in writing made between partners specifying the amount of each partner's investment in money, labor, or skill, the time the partnership is to continue, the division of losses and gains, and all other conditions forming the mutual understanding upon which the partnership is based.

Stock companies are often formed for the management of large business enterprises in order to avoid the personal liability involved in ordinary copartnerships and also to more easily perpetuate the business. Each state has special statutes regulating the formation of stock companies.

Sample Solution:

1. A, B, and C are partners to share gain or loss in proportion to investment. A invests $3000, B $4000, and C $5000. They gain $3600. Find each man's share of the gain.

$3000
4000
5000
$12000 whole capital

$\frac{3000}{12000}$ = 1/4 A's part of capital.

$\frac{4000}{12000}$ = 1/3 B's " " "

$\frac{5000}{12000}$ = 5/12 C's " " "

1/4 of $3600 = $900, A's gain.

1/3 of $3600 = $1200, B's gain.

5/12 of $3600 = $1500, C's gain.

Explanation.—The whole capital, $12000, is found by adding the investments of the individual partners. Since A invested $3000, his part of the whole capital is represented by the fraction $\frac{3000}{12000}$, or ¼. Likewise B's part of the whole capital is $\frac{4000}{12000}$, or 1/3, and C's $\frac{5000}{12000}$, or 5/12. A's capital being ¼ of the whole capital, his gain will be ¼ of the whole gain; hence A's gain is ¼ of $3600 = $900. For the same reason, B's gain is 1/3 of $3600 = $1200, and C's gain is 5/12 of $3600 = $1500.

Sample Solution:

2. C and D are partners in business, sharing the loss or gain in proportion to their average investments. C invests Jan. 1, $3000, June 1, $2000. D invests Jan. 1, $5000, and withdraws Aug. 1, $1500. Their net gain for the year is $2050. Find share of each.

$3000 × 5 = $15000 for 1 month.
5000 × 7 = 35000 " " "
C's investment = $50000 " " "
$5000 × 7 = $35000 " " "
3500 × 5 = 17500 " " "
D's investment = $52500 " " "
$50000
52500
$102500 = whole capital for 1 month.

$\frac{50000}{102500} = \frac{20}{41}$ C's share of the total investment.

$\frac{52500}{102500} = \frac{21}{41}$ D's share of the total investment.

$\frac{20}{41}$ of $2050 = $1000, C's gain.

$\frac{21}{41}$ of $2050 = $1050, D's gain.

Explanation.— C's first investment, $3000, was in the business unchanged until June 1, or 5 months. The use of $3000 for 5 months is equivalent to 5 times $3000, or $15000 for 1 month. June 1, C invested $2000 more, which made his total investment $5000. This $5000 was in the business the remainder of the year, or 7 months, which is equal to 7 times 5000, or $35000 for 1 month. By adding the $15000 and the $35000, C's total investment is found to be equivalent to an investment of $50000 for 1 month.

D's investment, $5000, was in the business unchanged until Aug. 1, or 7 months, which is equivalent to the use of $35000 for 1 month. On Aug. 1, D withdrew $1500, leaving him only $3500 in the business for the remainder of the year, or 5 months, which is the same as $17500 for 1 month. By adding $35000 and $17500, D's total investment is found to be equivalent to an investment of $52500 for 1 month. $50000 added to $52500 shows that the net investment of the firm is equivalent to an investment of $102500 for 1 month. Since C's investment is equal to $50000 for 1 month, his share of the whole investment is $\frac{50000}{102500}$ or $\frac{20}{41}$; hence, he is entitled to $\frac{20}{41}$ of the gain, or $1000. In the same manner, D's share of the whole investment is $\frac{52500}{102500}$ or $\frac{21}{41}$, and he is entitled to $\frac{21}{41}$ of the $2050, or $1050.

SQUARE ROOT

Rule.—

1. Point off the number into periods of two figures each, commencing at the right, or at the decimal point. Find the greatest square in the left-hand period, and write its square root as the first figure in the root. Subtract the square of this first root figure from the left-hand period and bring down the next period for a new dividend.

2. For a trial divisor, multiply the root already found by 2, and annex one cipher. Divide the new dividend by the result thus obtained, and write the quotient as the next figure in the root. Add the last-found figure of the root to the trial divisor, and multiply the sum by this same last-found figure of the root. Subtract the product from the new dividend and bring down the next period for a second new dividend.

3. Continue this process until all the remaining periods have been brought down and the root obtained.

Notes.—1. There must be a figure in the root for every period in the power.

2. In pointing off a number involving a decimal, as 31462.874, start at the decimal point and divide into periods going to the left on the whole number and to the right on the decimal. In case there is but one figure in the right-hand period of the decimal, annex a cipher to complete the period. Thus the above number pointed off into periods would appear, 3'14'61.87'40.

Example: Find the square root of 576 sq. ft.

Solution:

```
5'76|24
 4
44|176
  |176
```

CUBE ROOT

Rule.—

1. Separate the number into periods of three figures each, beginning at the right, or at the decimal point.

2. Find the greatest cube in the left-hand period, and place its cube root as the first figure of the required root. Subtract the cube of this root from the left-hand period, and bring down the next period to make a new dividend.

3. Multiply the square of the root already found by 3 and annex two ciphers, for a trial divisor. Divide the new dividend by this trial divisor and write the quotient as the next figure in the root.

4. Multiply 3 times the first part of the root by the last-found root figure, annex one cipher and add the square of the last root figure; then add this sum to the trial divisor for a complete divisor.

5. Multiply the complete divisor by the last figure of the root; subtract the product from the new dividend, and bring down the next period for a second new dividend.

6. Continue this process until the root has been found.

Example: Find the cube root of 91125 cu. in.

Solution:

```
91'125|45
 64
4800|27125
 600|
  25|
5425|27125
    |
```

SIMPLIFIED ARITHMETIC

A PRACTICAL TREATMENT

FOR

THE BUSINESS WORLD

EVERYDAY ARITHMETIC

Practical Arithmetic. Our treatment of the subject will be from the practical standpoint of the world of business; arithmetic as it is actually needed outside the school-room rather than the highly artificial work which is still, unfortunately, found in many text-books that are widely used.

In every day life we work commonly with integers, or integers and decimals, of not more than 4 places; we use $2.75 or 37 cents or $1.15 or 18 much more frequently than we use $27,500 or 3,287,246. Real and vital instruction will deal with the numbers such as we use constantly. In fractions we rarely use any other denominators than 2, 3, 4, 5, 6, 8, 10, 12 and 16; our practice work in fractions should deal largely with these denominators, until we can handle them easily and accurately. Problems to be solved without pencil and paper meet us every day and so do problems in which we need only a rough, an approximate answer; practise must be given in this kind of work. If taxes, stocks and bonds and life and fire insurance are to be presented to the children of our eighth grades then these topics should be treated as they are in real life. Arithmetic in every school should be adapted to the business life of the community in which the school is located.

RULES FOR SPEED

Mental Arithmetic—Speed Rules.

1. *Learn the 45 fundamental combinations of addition and multiplication.*
2. *Work from left to right, mentally, and not from right to left.*
3. *Use constantly, wherever possible, the fact that we have a decimal system of numbers, a system based on ten and powers of ten.*
4. *Learn to think numbers.*

ONLY FORTY-FIVE COMBINATIONS TO LEARN

The 45 addition and multiplication combinations must be made by drill absolutely automatic. The combination 7 when you look at it and *think* addition

8

–

must spell 15 in just the same way that *c a t* spells *cat*.

In drill work do not place —, +, or × signs before the lower digit: this retards the child's progress later. Drill on the combinations mentioned just as they are to be used; drill by having the combinations written at random, selecting from all those which are given in our tables but not keeping them in order.

RAPID ADDITION

How to Add Rapidly.

After learning the 45 combinations in addition the next step for rapidity is to learn to add mentally any two two-place numbers. With the 6 combination

8

associate such combinations as 16 6 6 46, and further those like 26 13 68
8 28 68 8 38 76 26
88. Read these sums from left to right; thus in reading 68 you think first 80,
46 26
then 94, a glance to the right showing that one is to be carried making the 80 into 90.

4 In reading the sums in column addition you begin by reading the sum
7 of the first two digits; read only the sums. Thus you here read 8, 17, 21,
8 27, 35, 42, 46 or 8, 17, 27 (since as you come to the 4 and 6 you notice that
6 this adds ten to the preceding 17), 35, 42, 46.

4 In adding numbers which are near to even hundreds notice that you
9 can frequently save time by adding the full number of hundreds and sub-
3 tracting the small difference.

5	396	388	693
–	425	475	281
	821	863	974

Think 400+425 less 4, gives 821; in the second problem think 400+475—12 =863; in the third, 700+281—7 =974.

SPEEDY MULTIPLICATION

How to Multiply Rapidly. No tables of elevens and twelves should be separately learned; particularly with a child who has difficulty with arithmetic these tables increase the troubles and give no return value. No one multiplies by 12 as a single multiplier and even in business there is no more need for the tables of elevens and twelves than for fourteens or eighteens. Learn the combinations automatically up to 9
9
—
81

Learn to multiply mentally any two place number by a single digit; multiply from left to right, and add mentally. So in getting the product 8×17 or 17,

8

think 8×10 is 80, 8×7 is 56, added gives 136. With a little practise you can do this mentally more quickly than you can say the partial products. In 8×27, *think* 160, 56, 216.

MULTIPLICATION TABLE UP TO 20 x 20 MADE EASY

An Easy Rule for the Product of Any Two Teens. To multiply any two numbers between 10 and 20 do as follows; to the whole of one-teen, add the units of the other, and annex a zero; to this number add the product of the units. Example, 18×17, the units are 8 and 7 respectively. To the whole of one, 18, add the units, 7, of the other, making 25; to this annex a zero (multiplies 25 by 10), and add to the result, 250, the product 56 of the units, 7 and 8, giving 306. Mentally to multiply 19 by 14, the following numbers pass rapidly before your mind's eye, 19, +4, 23, 230, 36, *266* which is the product.

Combining this rule with the preceding rule for the product of any two place number by a single digit gives the complete multiplication table up to 20x20. Thus in the product 8x19, the following numbers pass rapidly before the mind's eye, 80, 72, *152*, which is the product.

PRODUCTS OF EVEN TENS

When the Tens are the Same. If you have two numbers beginning with the same tens' digit, you add the whole of one number to the units of the other and multiply by the tens' digit; annex a zero, and to this number add the product of the units. 24×27 is 20×(20+4+7) +4×7; in doing this mentally, 27, you think
24
27, +4, 31, ×2, 62, 620, +28, 648. If the units sum to ten as in 87, 26, 92, or
83 24 98
35 the product has in the last two places the product of the units and in the first
35
one or two places the product of the ten's digit by a number one greater. Thus 87
83
begins with 8×9 and ends with 3×7, 7221; 26 has 6 in the first place (2, the
24
tens' digit ×3, one more than the tens' digit) and 4×6 in the last two places, 624; 92×98 is 9×10 placed before 8×2, or 9016; 35×35 is 3×4 placed before 5×5, or 1225.

LEARNING BY DOING

General Rules. Let the child begin real multiplication examples long before he has all the tables fully memorized; the work will help to make the tables automatic. With a backward child, allow him to write out the tables in vertical form,

2	3	4	5	6	7	8	9
8	8	8	8	8	8	8	8, and use these tables in working actual
—	—	—	—	—	—	—	—
16	24	32	40	48	56	64	72

problems; he will soon learn the tables by using them.

EASY MULTIPLIERS

Quick Multipliers. To multiply by 10, 100 or 1000, annex one, two, or three zeros, respectively, to the multiplicand. To multiply by 5, 50, or 500 multiply
10, 100,
by 10, 100, or 1000, as above, and divide by 2 since $5=\frac{}{2}$, $50=\frac{}{2}$ and $500=$
2
1000. To multiply by 2.5, 25 or 250, multiply by 10, 100 or 1000, as before, and
2
divide by 4, since $2.5=\frac{10}{4}$, $25=\frac{100}{4}$, and $250=\frac{1000}{4}$. To multiply by 7.5, 75,
4 4 4
or 750, multiply by 5, 50 or 500 and add to this product, in each case, ½ of itself.
4300
Examples: 25x48 is —— or 1200; 50×48 is 2400; 75×48 is 2400+1200 or 3600
4
To multiply by ¾, think of ¾ as ½+¼, to ½ the number add ½ of ½ of the number; ¾ of 48 is 24+12 or 36.

50 and 25 are called aliquot parts of 100; two other aliquot parts of 100 are frequently useful, 12½ or ⅛ of 100, and 33⅓ or ⅓ of 100. If you wish to know approximately what 34 or 35×186 you can at a glance state that 33⅓×186 is 186×100 or 6200, and 34×186 is 2/3 of 186 or 124 more than 6200.

3

EFFICIENCY RULES

Multiplication of Decimals Abbreviated. In finding the cost of 328.4 lbs. of milk at $3.38 per hundred it is not necessary to multiply in the ordinary way $3.38 by 3.284 as this gives numbers in the fifth decimal place where nothing finally beyond the second decimal place is needed.

3.380	In any product of decimals remember that the first place
3.284	times the first gives second place, and first times second gives
	third place, and so on. In such a product begin with the highest
10140	place of the multiplier and carry results one place farther
676	than desired in the final result. If both numbers have not
270	the same number of places make the number of places agree
13	by adding zeros as above.

11.099 or $11.10

Multiply .37628×.41329, retaining finally only 4 places of decimals.

.37628	Begin to multiply with the highest place of the multiplier, not
.41329	the lowest.
	Begin 4×2, 8 in 5th place, carry 3 from 4×8, making 11. Then
15051	4×6, 24+1, 25, etc. Cross out the 8 and the 2 in upper number.
376	Then 1×6, 6, nothing to carry since 1×2 is less than ½, etc. Cross out 6.
113	Then 3×7, 21, +2 carried from 3×6 =18, etc. Cross out 7.
7	Then 2×3, 6, +1 (from 14), 7. Cross out 3 above.
3	Then 3, carried from 9×3 =27 which is nearer 3 than 2 in the fifth
	place.
.15550	Final result, .1555.

EFFICIENCY IN DIVIDING

Short Cuts in Division. In division, many unnecessary figures can be cut off when only an approximate result is desired. If 3280 articles are manufactured at a total cost of $18,834, what is the cost per article, to one cent?

	5.742		5.74
3280)	18,834		3280) 18,834
	16,400		16,400
	2434	0	2434
	2296	0	2296
	138	00	138
	131	20	131
	6	800	7
	6	560	
		240	

After each division cut off one figure in the divisor and use the part left as new divisor; this will keep the right hand digit of all the partial products in a vertical line.

Long Division Made Short. Use the form of short division for long division, and teach children to see that it is the same process. Some children are assisted by having the complete form of quotients and partial products retained in the explanatory solution.

```
                7
               30
              400
              ---
134)58639     437
 53600      for 134)58639
 -----          536
  5039          ---
  4020          503
  ----          402
  1019          ---
   938          1019
   ---          938
    81          ---
                 81
```

ELIMINATING PARTIAL PRODUCTS

The Addition Method in Division.—By using the additive method of subtraction, subtracting from the dividend each part of each partial product as it is obtained, only the remainders need be written, leaving the work quite compact.

```
  437        4 in the quotient is obtained in the usual way.
134)58639
  50       Now 4×134 is to be subtracted, by the additive method,
 101       from 586.
  81         Then 4×4 is 16, +0, makes 6; the 0 is the first figure in the
             remainder; 4×3, 12, +1 carried from 16, 13, +5, makes 18. 4×1,
             4, +1 carried from 18, 5, +0 makes 5.
               Then 3×4, 12, +1, 13; 3×3, 9, +1, carried from 13, 10, +0, 0;
               3×1.
               3, +1 from 10, 4, +1 makes 5.
                 Then 7×4, 28, +1, 29; 7×3, 21, +2 from 28, 23, +8, 31;
                 7×1, 7, +3, 10.
                   50 is the first, 101 the second, and 81 the third remainder.
```

THE CHECK BY NINES

Casting Out Nines. When 4,328 is divided by 9 the remainder is the same as when 4+3+2+8 is divided by 9; 1000 is 999+1, 100 is 99+1, 10 is 9+1; when 1000 is divided by 9 the remainder is 1, when 100 is divided by 9 the remainder is 1, when 10 is divided by 9 the remainder is 1;

when 4000 is divided by 9 the remainder will be 4×1 or 4;
when 300 is divided by 9 the remainder will be 3×1 or 3;
when 20 is divided by 9 the remainder will be 2×1 or 2;
8 divided by 9 gives as remainder 8.

The total remainder of 4,328 divided by 9 is 4+3+2+8, the sum of the digits, and out of these we can *cast a nine* leaving 8 as remainder. When you have the sum of a column of figures nines can be cast out of all the summands, and the total remainder should be the same as the remainder when nines are cast out of the sum; in subtraction the difference of the remainders of minuend and subtrahend should be the same as the remainder when nines are cast out of the remainder (the answer); in multiplication the remainder, by nines, of the product is the same as the product of the remainders. In division the remainder of quotient, multiplied by remainder of divisor, and added to the remainder's remainder, equals the remainder of dividend

```

DECIMALS—SEE THE POINT

The Point about Decimals. If the decimal point is kept straight there is absolutely *no difference* between division of decimals and division of integers. If .1437 is divided by .123 your quotient will evidently be a little more than one, as 14 hundredths contain 12 hundredths once and a little over; .01437÷.123 gives .1 as first place in the quotient since .1 of .123 is .0123. If in doubt multiply both dividend and divisor by 10, 100, 1000, so as to have the divisor an integer; then the number of places in the dividend required to obtain your successive remainders equals the number of places in the quotient.

The Rule. The number of places in the quotient + the number of places in the divisor must equal the number of places in the dividend. Remember that the quotient multiplied by the divisor must equal the dividend, except for the small remainder.

```
                                        .01
                                       ----

                                      .0002
                                     ------
For .62)000143, write 62).0143; or write .0002
                                     ------
                  124                .62).000143
                 -----                   ^124
                  19                     ---
                                          19
```

STANDARDIZING ARITHMETIC

Trouble Points.—How to Locate Them. In large factories they hold stop-watches on men who are doing the same kind of work to compare the daily out-put of the men; every man is expected to come up to a certain standard of production. In arithmetical operations there are certain standard rates at which pupils in different grades should be able to perform these operations.

```
7 6 3 0 8 9 1 6 4 2 7 2 5 4 8 3 9
8 4 2 5 5 4 3 6 3 7 5 8 9 6 1 0 8
- - - - - - - - - - - - - - - - -
```

Place on paper before the child, or have him copy, about 100 of these addition or multiplication combinations, be sure to include all combinations up to 9 with 9 and some combinations involving zero. Time the child, using a watch with a second hand; have paper and pencil prepared; have the child hold up his hand with the pencil, telling him 5 seconds before the minute hand reached 60 to get ready; at exactly the 60 mark, say "Write." The time of copying the examples is not to be included; take only the time of writing the series of answers to problems *previously* copied.

In one minute a child should be able to write the answers, correctly, as follows, depending upon the grade in school:

Addition Combinations	III 26	IV 34	V 42	VI 50	VII 58	VIII 63	Middle of Grade

The same combinations, recopied, can be used for multiplication; the inverse combinations can be used for subtraction and division (inverse of 7 is 15 or 15; 8 7 8 / 15 — inverse of 7 is 7)56 or 8)56)

```
  8
  -
  7

 56
```

STANDARD SCORES

	III	IV	V	VI	VII	VIII
Multiplication	16	23	30	37	41	45
Subtraction	19	25	31	38	44	49
Division	16	23	30	37	44	49
Copying Digits	63	75	84	92	100	108

AVOID DRILL WITHOUT PURPOSE

If a child falls below standard in all four fundamental operations the probability is that he is slow in copying digits. The standard scores for copying digits are for copying, from a printed (or carefully written) sequence of digits, written in no systematic order, e. g., 3, 4, 0, 7, 6, 8, 5, 2, 4, 9, 1, 3, 5.

Take the time you make with each of the four operations. Find out in this way just where your arithmetical weakness lies. Having located the trouble point, drill on that particular work, following the methods indicated in the preceding articles.

Another good type of time drill, devised like the preceding by Mr. S. A. Courtis of Detroit, involves the actual fundamental operations in problems. In addition, place before the individual to be tested about 25 problems, each consisting of nine three-place numbers, time 8 minutes; in subtraction set 24 problems each consisting of an eight-place number to be subtracted from an eight or nine place, time 4 minutes; in multiplication, set 24 problems each consisting of a four place number to be multiplied by a two-place or a three-place number with a zero, like 250, time six minutes; in division place a 4 or 5 place number divided by a two place, having an exact quotient of three places, time eight minutes.

STANDARDS SET FOR THE PRECEDING EXERCISES

	IV	V	VI	VII	VIII
Addition	6	7	9	10	11
Subtraction	6	8	9	10	12
Multiplication	4	6	7	8	9
Division	3	5	6	7	9

After a child attains the standard for his grade in any operation his time should be devoted to bringing up his record in the other operations, and to practical applied problems.

BUSINESS ARITHMETIC

Interesting Interest. (See Index.) At the present time the rules of interest and the problems, should be concerned with the real practise of banks and particularly with war savings. Take the $5.00 first government war savings stamps, sold when issued at $4.12 which pay 4% compound interest. Find the interest on $4.12 and add it to the principal at the end of the first year; do this for five years, carrying the work only to the second decimal price; the result will be the $5.00 which the Government agreed to pay at the end of 5 years. The process illustrates fully the fundamental principles of compound interest. Discuss postal savings bank, according to the actual rules, and discuss the Liberty Bonds This will make interest interesting.

Problem.—Compound interest on $4.12 for 5 years at 4%.

```
$4.12   $4.12                    $4.28   $4.28
 .04     .16                      .04     .17
-----   -----                    -----   -----
 .1648  $4.28 end of 1st year.    .1712  $4.45 end of 2nd year.
$4.45   $4.45                    $4.63   $4.63
 .04     .18                      .04     .18
-----   -----                    -----   -----
 .1780  $4.63 end of 3rd year.    .1852  $4.81 end of 4th year.
        $4.81   $4.81
         .04     .19
        -----   -----
        .1924   $5.00 end of 5 years.
```

At the end of the fourth year, interest .1852, only 18 cents is credited as in the preceding year the next larger unit, .18, was taken instead of .1780.

NOTE NOTES

Notes on Interest on Notes. (See Index.) Ninety-nine notes out of a hundred are now drawn for 2 months, or 3 months or 6 months, and in most parts of the U. S. at 6% interest. Whether the interest is paid when the note becomes due, or whether it is taken out in advance as discount, the method of computation is the same. Since the interest for 12 months is 6%, the interest for 2 months is 1% of the principal; the interest for 1 month is ½% of the principal; the interest for 3 months or 6 months is respectively 1½% or 3%.

Moving the Decimal Point. The interest on a note of $490 for 2 months, or 60 days, at 6%, is obtained by simply moving the decimal point two places, $4.90 is this interest; moving the decimal point again gives the interest for one tenth of 60 days, or $0.49 for 6 days. For one month take one-half of the interest for 2 months; for 90 days add these two. Work from the interest for 60 days, and it will be easy.

To find the interest at 5% or 7%, subtract or add, respectively, to the interest which you find at the 6% rate, one-sixth of itself. For 4½% take from the interest at 6% one-fourth of itself.

Discount is Interest. The principles of discount are fully discussed in the preceding section, as discount is nothing but interest taken out *in advance*. The discount on a note of $490 for 60 days at 6% is $4.90; the bank gives to the maker of the note not $490, but $490 less the *discount*, $4.90.

COMPOUND INTEREST

How Money Grows. One dollar placed at interest for one year at 6% grows to $1.06; in five years at compound interest it grows to $1.338, and in ten years to $1.790; at the end of 12 years the dollar has more than doubled itself.

HOW ONE DOLLAR GROWS!

	4%	5%	6%
1 year	1.04	1.05	1.06
5 years	1.216	1.276	1.338
10 years	1.480	1.628	1.790
12 years	1.601	1.795	2.012
15 years	1.801	2.078	2.396
18 years	2.025	2.406	2.854
20 years	2.191	2.653	3.207
50 years	7.106	11.467	18.420
100 years	50.504	131.501	339.02

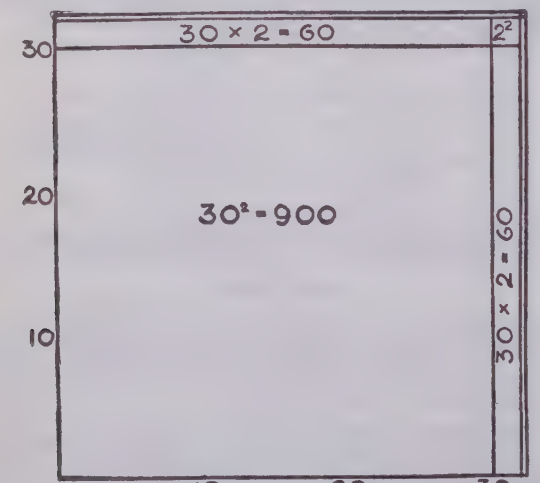
MEASURES AND MONEYS

Denominate Numbers. (See index for tables.) So far as practical problems are concerned these should deal, in general, with only two denominations; to change miles to inches is arithmetical exercise, but the practical value is almost *nil*. Children in public schools should not be required to learn Troy and apothecary tables, and obsolete measures; their work should be on the measures which ordinary people use in ordinary business.

SPENDING MONEY

How the Money Goes—Foreign and Domestic Exchange. (See Index.) Send the boy to the post-office to get a foreign and a domestic money order blank, send him to the Express office for similar blanks, show to the boy your checks as you send them even to out-of-town firms; when you have done these three things you can make clear to him the way money is sent from one place to another, whether at home or abroad. A boy who has *actually sent real money* by P. O. order, or by Express order, ot by his father's check knows more about domestic exchange than any book can teach him. Give the boy and girl a chance to do things in a real way, and arithmetic will become easy and interesting.

EXTRACTING THE ROOT



Square Root—the Easy Way. The easiest way to get square root is to find by trial, some number whose square is near to the given number; divide the given number by this trial root; half the sum of the trial root and the quotient, carried to only one place farther than the trial root, is a nearer trial root.

Example.—Find the square root of 153.16. Evidently 12 is near to the root.

```
  12.76
12)153.16
   12
   --
   33
   24
   --
   91
   84
   --
   76
   72
   --
    4
```

12 is too small; 12.76 is too large, since 12×12.76. Try $\frac{12+12.76}{2}$ or 12.38; taking the nearest number one place, farther gives 12.4 which is shown, by division, to be the exact root.

The ordinary process of square root can be readily explained by a diagram on cross-section paper which can be procured at any book-store, or supply house.

Build up on the diagram $(32.4)^2$ as $30\ (+2+.4)^2$. Note that 30^2 is 900, the larger square; 32^2 is $30^2 + 2 \times 30 \times 2$ (the two rectangles) $+2^2$ (the little square), $(32.4)^2$ is 32^2 (the second of the large squares, with side 32) $+2 \times 32 \times .4$, or the two rectangles, one at the side and one at the top, with longest dimension 32 and shorter dimension .4. Note that in extracting the square-root of 1049.76 you take out these squares and rectangles and little squares in the order mentioned. Looking at 1049 you see that 30 is the largest even ten who e square can be taken out of 1049.76. Doubling 30 gives 60, the total length of our two rectangles which are at the top and side of our square of side 30. Dividing 149 by 60 we see that the width of these two rectangles is greater than 2 and less than 3. We add the 2 to 60, making 62 and multiply by the 2, giving $2 \times 60 + 2 \times 2$ or the area of the two rectangles and the little square of side 2.

```
  32.4
30)1049.76
   900   the large square
60 149.76
62 124
 2
--  -----
64  2576
```

Now we have taken out $900+124$ or 1024 which is the square of 32. The total length of the two rectangles, at top and side of our square of side 32, is 64. Divide 25.76 by 64 and we get .4; evidently the other dimension of our long, narrow rectangles is near to .4; to the 64 add the .4 and multiply the sum by .4 giving the area of the two narrow rectangles $.4 \times 64$ or 25.6 and the area of the tiny square of side .4, $.4 \times .4$ or .16, total 25.76.

Problem. Extract the square root of 1176.49, both methods.

In each method begin by dividing 1176.49 off in periods of two digits each way from the decimal point. The root of this number will then have two places to the left of the decimal point. The first trial root is 30, since 30^2 is 900 and 40^2 is 1600.

By Division.

```
  39.2
30)1176.49
   90
   ---
   276
   270
   ---
    64
```

$1176.49 \div 30 = 39.2$

30 is too small; 39.2 is too large.

Try $\frac{1}{2}$ (30+39.2) or 34.6.

$1176.49 \div 34.6 = 34.00$

```
34.6)1176.490
   1038
   ----
   1384
   1384
   ----
     90
```

34.6 is too large; 34. is too small.

Try $\frac{1}{2}$ (34.6+34) or 34.3

```
  34.3
34.3)1176.49
   1029
   ----
   1474
   1372
   ----
   1029
   1029
```

34.3 is the number which multiplied by itself gives 1176.49.

By Regular Process.

```
 3 )1176.49
    9
   ---
64  276
    256
    ---
68.3 20.49
      2049
```

the 3 for 30, the 9 for 900, 30^2; the 6 (first 3 doubled) for 60; divide 276 by 60 gives 4; annex to 6, 64×4, gives two rectangles 4×30 and 4×30 and little square 4×4.

The 4 doubled, 68; and $20.49 \div$ by 68 (or 20 by 60) gives .3; annex to 68. $68.3 \times .3$ gives two rectangles $34 \times .3$ and $34 \times .3$ and tiny square $.3 \times 3$.

BIG BUSINESS

Stocks and Bonds. Stock brokers charge $\frac{1}{8}$ of one dollar for buying or for selling a share of stock, with a minimum charge of $1.25, the price of buying or selling 10 shares of stock. The minimum charge is disregarded in ordinary arithmetical work. To find the price of a share of stock to a purchaser add $\frac{1}{8}$ to the quotation, which on reliable stocks is given in dollars and fractions of dollars; to find the price received by one who sells given shares of stock through a broker, subtract from the market price, $\frac{1}{8}$, and multiply by the number of shares sold. Brokers usually make a separate item on the bill for their brokerage. On bonds the brokerage is commonly computed on each $100 of the face of the bond. To make this work mean anything to a boy or girl in the eighth grade, get a newspaper which gives stock quotations and make up actual problems from actual quotations in the paper.

GOVERNMENT ARITHMETIC

Duties, Customs, Commission. (See Index.) The fundamental idea in duties *ad valorem* (on the value) and commission on price of articles bought or sold is precisely the same. In each case a certain *percentage* of the money is found; when the government receives this percentage for permitting the goods to be imported into the country (or for permitting the manufacture as in liquor) it is called *duty*, but when the buyer or seller of goods receives the percentage as pay for buying or selling the goods, the percentage is called commission. A *duty* of 15% on books worth $400, at the price of purchase, is the same in value as a commission of 15% on selling 400 bushels of corn at $1.00 per bushel. *Customs revenue* or *tariff* or *duty* determined on the quantity of goods imported, irrespective of the cost, is called *specific duty*; to find this duty is always a matter of multiplication.

Problem. Find the import duty on 400 lbs. of Cigars, at $4.50 per lb. *Specific duty*, plus 25% *ad valorem*; value of cigars, $1200.

$4.50	$1200	$1800
400	.25	300
$1800 *specific* duty.	$ 300 *ad valorem* duty.	$2100 total import duty.

If these cigars were sold for $4500, with a commission of 10%, the importer would receive not $4500 from their sale but $4500 less 10% of $4500.

$4500	$4500
.10	450
$ 450 commission.	$4050 net proceeds of sale.

ARITHMETIC ON THE FARM

Gallons in a Gasolene Tank. Measure the diameter of the circular base and the height in inches; multiply the diameter by itself and the product by the height; take $\frac{1}{2}$ of 1% of this number and the result is the number, correct to one gallon for any tank holding less than 50 gallons. Where greater accuracy is desired, add to this 1 gallon for every 50 gallons, and proportionally for smaller parts (i.e., add 2% of your first result).

Find capacity in gallons of a tank 15 inches circular base, by 20 inches high, $15 \times 15 \times 20 = 4500$; 1% is 45; $\frac{1}{2}$ of 1% is 15. The tank holds 15 gallons, or, if accurately measured, you can add 2% of 15, or 3 gallons. A circular tank, 30 inches diameter by 36 inches high, holds $108 + 2.16$ gallons, or about 110 gallons. Computation $30 \times 30 \times 36 = 32400$; take $\frac{1}{2}$ after moving decimal point two spaces, gives 108; for greater accuracy, add 2% of 108 or 2.16. Total capacity, 110.16 gallons.

The 1918 Ford tank is 10 inches in diameter by 30 inches long. $10 \times 10 = 100$, $100 \times 30 = 3000$; 1% is 30; $\frac{1}{2}$ of this gives 10 gallons, *the capacity*.

The rule depends, of course, on the formula $\frac{3.1416 \times d^2 \times h}{4 \times 1728} \times \frac{15}{2}$. The area of a circle is $\frac{3.1416 d^2}{4}$ or $\frac{22 \times d^2}{7 \times 4}$ where d is the diameter; $\frac{22 \times d^2 \times h}{7 \times 4}$ is the volume of a circular cylinder of height, base of diameter d; $\frac{22 \times d^2 \times h}{7 \times 4 \times 1728}$ is the volume in cubic

feet, 1728 cu. in = 1 cu. foot; since a gallon contains 231 cu. in., a cubic foot equals 7½ gallons giving an error, of excess, of 2 gallons in 100 cu. feet (100 cu. ft. = 748.05 gallons). $\frac{22\times d^2\times h\times 15}{7\times 1728\times 2} = .00341\times d^2\times h$, and using the more accurate values 7.48 instead of $\frac{15}{2}$ and 3.14159 instead of $\frac{22}{7}$, gives .003399 or .003333 +.000066; now ⅓ of 1% is .003333, and 2% of this number is .000066; this sum gives our required .003399, and so the above rule.

THE CISTERN MEASURED

Barrels in a Cistern. Take the diameter and the height in feet, multiply the square of the diameter by the height; of this number take 1/6 and also take 2%; the sum gives the number of barrels within 1 barrel in 1000.

How many barrels in a cistern 8 feet in diameter, 9 feet high? 8×8×9 = 576; 1/6 of 576 = 94; 2% of 576 is 11.52; 94 + 11.52 = 105.52 bbl.

Check up on this by finding the number of cubic feet in the cistern $\frac{22\times d^2\times h}{7\times 4}$ and dividing by 4.21, which is the number of cubic feet in a barrel (31½ gallons).

For a square tank find the number of cubic feet and divide by 4.2 or 4.21; or take ¼ of the number of cubic feet and from this number subtract ½ of 1/10 of itself. Thus a tank 8×8×9 holds ¼ of 8×8×9 or 144 bbls. less 7.2 bbl. (1/10 of 144 is 14.4, and ½ of this is 7.2 bbl.).

GAUGING THE SILO

Capacity of Silos. To find the number of cubic feet of content within a silo, measure accurately the inside diameter. Square the diameter and divide the result by 4; this number multiplied by 3 1/7 gives the number of cubic feet per foot of height.

Problem. How many cubic feet in a silo 24 feet high, with inside diameter 12 feet, 14 feet, 16 feet?

12×12 = 144; 144÷4 = 36; 3 1/7 × 36 = 133 1/7 cu. feet per foot of height; 24×113 1/7 = 2715 cubic feet.

14×14 = 196; 196÷4 = 49; 3 1/7 × 49 = 154; 24×154 = 3696 cu. feet.

16×16 = 256; 256÷4 = 64; 3 1/7 × 64 = 201 1/7; 24×201 1/7 = 4827 cu. feet.

For 13, 15, and 17 foot diameters, you would get 3187, 4243, and 5450 cu. ft. for this height, or 132 5/6, 176 5/6, and 227 cu. ft., respectively, per foot of height. No appreciable error is made if with a 12½ foot silo, or 14½ foot silo, you take the middle value, thus between the 12 foot and 13 foot values of 113 1/7 and 132 5/6 you find 123 as middle value, ½ (113 1/7 + 132 5/6).

In general in measuring the capacity of silos the computation should not be carried out beyond whole cubic feet, as the measurements of silos are not sufficiently accurate to warrant carrying the computation to fractions.

A SILO CAPACITY TABLE

The Silo Table. This table gives for 12 to 18 foot circular silos the capacity in cubic feet and in tons, figuring 40 lbs. of silage to the cubic foot; heights of 20, 24, and 30 feet are given.

	12 Foot		13 Foot		14 Foot		15 Foot		16 Foot		17 Foot		18 Foot	
Height	Cu. Ft.	T'ns	Cu. Ft.	T'ns	Cu. Ft.	T'ns	Cu. Ft.	Tons	Cu. Ft.	Tons	Cu. Ft.	Tons	Cu. Ft.	Tons
20 feet..	2262	45.2	2655	53.1	3080	61.6	3536	70.7	4023	80.4	4541	90.8	5089	111.8
24 feet..	2715	54.3	3186	63.7	3696	73.9	4243	84.9	4827	96.5	5449	109	6107	122
30 feet..	3393	67.8	3983	79.6	4620	92.4	5304	106	6035	120.6	6811	136.2	7633	167.7

CANCELLATION

The Ice by Cancellation. Cancellation simplifies calculation in many problems that arise in business. A cubic foot of ice, containing 12×12×12 cubic inches, weighs 56 lbs. How much ice will your ice box hold if it takes a piece 24×18×15 inches?

$$\frac{\cancel{24}^{2}\times\cancel{18}^{3}\times 15\times\cancel{56}^{14}}{\cancel{12}^{1}\times\cancel{12}^{1}\times\cancel{12}^{1}} \text{ lbs. or } 15\times 14 \text{ lbs. or } 210 \text{ lbs.}$$

A piece 8×9×12 weighs $\frac{\cancel{8}^{2}\times\cancel{9}^{3}\times\cancel{12}^{1}\times\cancel{56}^{28}}{\cancel{12}^{1}\times\cancel{12}^{1}\times\cancel{12}^{1}}$ lbs., or 28 lbs.

The same principle applies to finding the weight of 500 sheets of paper of size 33×45 inches when you know that 500 sheets 25×36 inches weigh 50 lbs. 500×33×45 will be the number of square inches of paper in the new ream; but 50 lbs. contains 500×25×36 square inches; the weight of the new ream is then

$$\frac{\cancel{500}^{1}\times 33\times\cancel{45}^{9}\times\cancel{50}^{10}}{\cancel{500}^{1}\times\cancel{25}^{5}\times\cancel{36}^{4}} = \frac{165}{2} \text{ lbs.} = 82\tfrac{1}{2} \text{ lbs. per ream.}$$

FRACTIONS MADE EASY

Refractory Fractions. No one in business has any use for such fractions as $\frac{17}{53}$ and $\frac{173}{379}$; it would be well in arithmetic to confine the work largely to those fractions which are used in business. Work many problems with ½, ⅓, ⅔, ¼, ¾, ⅜, ⅝, ⅞, ⅛, 5/6, fifths, tenths, twelfths, and sixteenths; get the fundamental principles firmly fixed in mind with these easy fractions, by much practise, then the drill with more awkward denominators will be easy.

Practise of This Kind. Problems.—Add ½ yd., ¾ yd., ⅜ yd. Note that ¾ is ½ + ¼; in adding mentally, combine ½ and ¾, giving 1¼, or 1 2/8; then add the 3/8, making 1 5/8. *Three quarters is a half and a quarter.* Find the cost of ¾ yd. ribbon at 24c a yd. Note that ½ yd. costs 12c, and ¼ yd. 6 cents, hence ¾ yd. costs 18c. At 18c a yard, a clerk should say 9 + 4½, gives 13½; the rule is to charge 14 cents if change is made, or 13 cents if the customer has exact change.

A BURNING QUESTION

Coal in Your Coal-Bin. Anthracite coal varies somewhat in weight per cubic foot, depending on the size and slightly on quality. However, 32 cu. ft. to 34 cu. ft. to the ton is about the average in ordinary sizes of coal. For all practical purposes 3% of the number of cubic feet in a bin gives the number of tons of anthracite coal which a bin will hold; ½% of this is approximately the number of tons of coke; 2½% of the number of cubic feet gives the number of tons of bituminous coal, which runs about 40 cubic feet to the ton.

Problem. Find the number of tons of coal in a bin 8×10×6 feet high; 8×10×6 = 480; 3% of 480 is 14.40, the number of tons of anthracite which this will hold; 2½% of 480 is 12, the number of tons of bituminous (Pocahontas or soft coal) which the bin will hold.

HAY

Hay in the Mow. Alfalfa hay stacked 30 days runs about 512 feet to the ton. A simple rule is to find the number of cubic feet in the mow by multiplying length by breadth by height, all in feet, then move the decimal point over three places and multiply by 2. This will be too large by one ton in fifty, unless the hay has been standing longer.

A mow 30×40×8 contains 9600 cubic feet; shift the point three places making 9.6 and multiply by 2, gives 19.2 tons for the capacity.

Hay in the Stack. A stack consists of a cone on a cylinder; measure the circumference of the cylindrical base and the height up to the point where the stack begins to taper off; multiply the circumference by itself and by 8 and divide by 100, giving the number of cubic feet for each foot of height of the cylindrical part. Multiplying by the height of the cylindrical part and shifting the decimal point three places gives one-half the number of tons in the cylindrical part. As the tops vary so much it is better to estimate the top separately as a fractional part of the base.

A stack of hay measures 60 feet in circumference and 14 feet high to the point where it begins to taper to the top. How many tons of hay?

$\frac{50\times 50\times 14\times 8}{100} = 2800$ cubic feet; moving the decimal point three places gives 2.8 as half the number of tons, or 5.6 tons for a new stack; a six months' stack will contain at least one-fourth more, and an old stack almost one-half more.

WHERE YOU ARE AND WHEN

Latitude and Longitude. (See Index in book.) This topic belongs rather to geography than to arithmetic. The difference between Eastern and Central time should be clearly understood, but elaborate problems on finding the difference in time between two places when the longitude is given have no real meaning in fact except for the astronomer. The sun rises in the East and sets in the West; of two points the one farther east is reached first by the sun so that sunrise takes place earlier at this place, than at the place to the west of it, consequently the time of day, by the sun, is later at the place farthest east. It takes the earth 24 hours to complete the rotation of 360° about its axis, and hence it takes the sun 24 hours to complete the apparent rotation of 360° about the earth; in one hour the sun, or earth really, completes 1/24 of its course, or 1/24 of 360°; a difference of 1 hour in time corresponds then to a difference of 15° of longitude.

In our table of longitudes value are given in hours, minutes, and seconds; multiplying by 15 would give the longitude in degrees, minutes, and seconds. Note that Washington in Eastern time is given as 5 hr. 8 min. +West, or earlier than Greenwich; Chicago in the Central time belt is 5 hrs. 50 min. +West, or about one hour earlier; Denver in the Mountain time belt is 6 hrs. 59 min. +West; and San Francisco in Western time is 8 hrs. 9 min. West. Note that Honolulu is 10 hrs. 31 min. +West, or earlier time than Greenwich, while Yokohama in Japan is 9 hrs. 18 min. East, or later time than Greenwich. Between these two points lies the part of the Pacific which can be considered as either 180° East or 12 hrs. later or as 180° West or 12 hrs. earlier Greenwich; then on the West of this line the date is one day later than on the East. A person who goes around the world westward apparently loses a whole day at the international date line in the Pacific, but he gains by single hours 24 hours as he progresses westward.

SENSIBLE MEASURES

Metric System. (See Index.) The metric system should be understood as a matter of general information, since so much of the civilized world uses that system at the present time. The interest of the boy in this subject can be aroused today by a discussion of the famous French 75-millimeter gun, and by discussing the rations of soldiers and civilians in France and Italy. An item taken from the daily newspaper is worth ten taken from the arithmetic.

Problem. About how large in inches is the 75 mm. gun? the 375 mm.? Our table, page 388, tells us that 10 millimeters = 1 centimeters, and 1 centimeter = .3937 inches. Now 5 centimeters or 50 mm. equals 1.968 inches and 2.5 centimeters equals one-half of this or .984 inches. The total is 2.952 inches; for all practical purposes of discussion, but not for making shells, the 75 mm. gun can be thought of as a three inch gun.

1 cm. is nearly 2/5 of an inch; 5 cm. make 2 inches, lacking .0325 inches, an error of 1⅓%.

ALGEBRA IS HIGHER ARITHMETIC

Algebra Applied to Arithmetic. In elementary algebra you learn that $(x+a)(x+b) = x^2+ax+bx+ab$; now this rule is equally good if we substitute 10 for x. Then $(10+a)(10+b) = 10\times 10+10\times a+10\times b+ab$, or $10(10+a+b)+ab$. If you think of a and b as numbers between 1 and 9, this algebraic formula gives the complete explanation for the rule which we have given above, under multiplication, for the product of any two "teens." Note that 10 + a is the whole of one number; b as the units of the other; 10 + a + b is the sum of one plus the units of the other; 10x (10 + a + b) is the product of this sum by 10; ab is the product of the units.

An easy rule for squaring numbers under 100 follows from an easy algebraic formula. $(50+a)^2 = 2500+100a+a^2$, $(50-a)^2 = 2500-100a+a^2$; or $(50+a)^2 = 100(25+a)+a^2$ and $(50-a)^2 = 100(25-a)+a^2$. The rule then is: find the difference between your given number and 150; if greater than 50, add this difference to 25, and if less, subtract from 25; to this number, resulting, annex two zeros (to multiply by 100); to this number add the square of the difference between 50 and your given number. Find $(57)^2$, $(43)^2$, $(62)^2$. In 57, a is 7, 25 + 7 = 32, 3200, $7^2 = 49$, 3249 = 57^2; in 43, a is 7 as 43 is (50—7); 25—7 = 18, 1800, 7^2 is 49, 1849 = 43^2; in 62, a is 12, 25 + 12 = 37, 3700, $12^2 = 144$, 3844 is 62^2.

As you work problems in algebra learn to substitute numbers, and so make your algebra useful in arithmetical computation.

MATHEMATICS APPLIED TO LIFE PROBLEMS

The training in accuracy and the familiarity with computation which is given by the work explained above is absolutely essential for the individual who works along scientific lines, whether in agriculture, commercial lines, or in the laboratory.

ALGEBRA

WHAT ALGEBRA IS. For three thousand years men have been looking for a brief way to write the explanations of arithmetic problems. The result of this search we call algebra. It is a systematic way of putting down the steps taken to get the answers to problems. It may be thought of as a sort of shorthand, making hard problems easier.

It also shows how to write arithmetic rules very briefly. We call these rules **Formulas** and find them very useful in learning about many things in science and in business and all sorts of practical affairs. We have formulas for interest and engines, electricity and lighting, ships and sailing, and the study of the stars, and for a thousand other things.

Algebra is not hard if you will study the *reason* for each step you take. Do not think of it as a rule but as the most sensible way to meet the difficulty you have before you. If you will study these paragraphs in this way you will find that you can solve many kinds of problems yourself and that you can read books that have formulas in their explanations, and even use these formulas yourself.

EQUATIONS. The most important tool that algebra uses in doing these things is the equation. To learn what an equation is and how it works is the biggest part of the study of algebra. We are now ready to take some problems and to find how to solve them by means of equations. Very simple ones will be best so that we shall not have to think much about the problem but about the method. It is a curious thing about beginning algebra that you must not think at all about what the answer is. Think only about how to get the equation. The answer will take care of itself.

PROBLEM 1. Four hundred fifty dollars is to be divided between John and Mary so that Mary will have 4 times as much as John.

Let j stand for the number of dollars John gets. Then 4 times j will stand for the number of dollars Mary gets. The algebra way of writing 4 times j is merely $4j$. We read it "four j." We think of it as four j's or as four times j.

We now know that $j+4j=450$. This is our equation. The word "equation" comes of course from the word equals. All of our equations will contain this sign, =, which we read "equals."

① $j+4j=450$

One j and $4j$'s make $5j$'s, so our second equation becomes

② $5j=450$

We want to know how many dollars j stands for. We know that $5j=450$. How shall we find j? You can see for yourself that we must *divide* by 5.

③ $j=90$

This means that John gets \$90. We also want to know Mary's share. The second line we wrote tells us that $4j$ stands for the number of dollars Mary gets. To get $4j$ from ③ we must multiply by 4.

④ $4j=360$

The answer is \$90 for John and \$360 for Mary. We show that this is the correct answer by adding \$90 and \$360 which gives us the right total, \$450.

The numbers ①, ②, ③, and ④ are going to be very useful in talking and writing about our equations. Form the habit of numbering each equation you write.

① is read "equation one."

This problem and its solution are very simple but if you have understood each step you have already gone a long way toward understanding what algebra is, and you are ready to go ahead.

The next problem can be done in the same way. We will put it down without the explanation. Study it carefully, rereading the explanation of problem one. Remember that you are laying the foundation for all your understanding of algebra.

PROBLEM 2. Father and Mother have 1800 books in all. If Father has 24 times as many as Mother, how many has each?

Let M = the number of books Mother has.

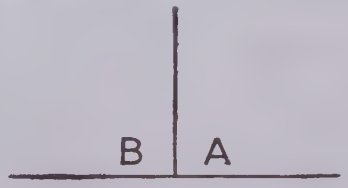
Then $24M$ = the number of books Father has.

①	$M+24M=1800$	
②	$25M=1800$	
③	$M=72$	②÷25
④	$24M=1728$	③×24

Check	*Ans.*
1728	Mother, 72 books
72	Father, 1728 books
1800	

Notice that we do not set down the units in the equations. In problem 1 we did not write dollars in the equations: nor did we write "books" in the equations of Problem 2. We do however set down these words in the *first lines* and in the *answer*.

At the right of ③ and ④ is written the explanation or "history" which tells exactly what was done in getting ③, namely divide ② by 25; and in getting ④, namely multiply ③ by 24. Always write your history *before* you write your equation.

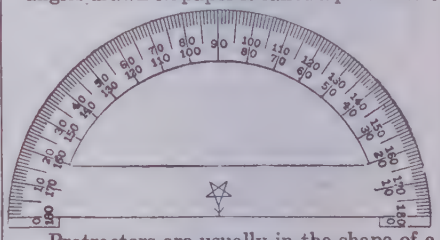


Where you have the answer to a problem your first question should be, "Is my answer right?" Look back to the problem. Both together had 1800 books. To see if we are correct, add the 72 books of Mother's to the 1728 of Father's and get the total 1800. This checks our solution. We *know* we are right.

The next problem is left for you to solve.

PROBLEM 3. There are twice as many lights on the first floor of a house as on the second floor. There are 48 lights on both floors. How many on each?

More of these problems can be found in the Evans & Marsh, First Year Mathematics.

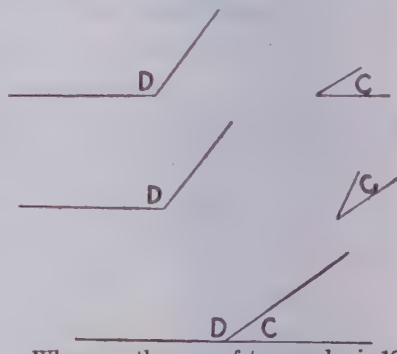


ANGLES. Our next problems are about angles. Before we are ready to solve them we will learn something about angles and their relations.

When two lines meet, as in the figure, so that $\angle A = \angle B$, (The symbol $\angle$ is read "angle"). Each angle is called a *right angle*. For the purpose of measuring smaller angles a right angle is divided into ninety equal parts called degrees. The angle A is 90 degrees. More briefly, $\angle A = 90°$. Also $\angle B = 90°$. If we let A stand for the numbr of degrees in the Angle A, we write

① $A = 90$
② $B = 90$
③ $A+B=180$ ①+②

The instrument used for measuring angles drawn on paper is called a protractor.



Protractors are usually in the shape of a half circle.

A very convenient form of protractor is the ruler-protractor made of celluloid.

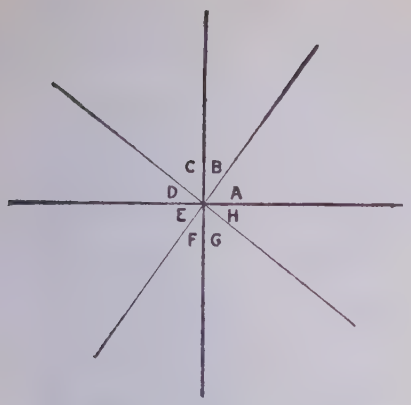
In each protractor you will notice the division into 180 degrees.

In each of these figures

$\angle C = 180°$

Whenever the sum of two angles is 180° the angles are supplementary. 50° and 130° are *supplementary:* so are 10° and 170°, 20° and 160°, 27.5° and 152.5°.

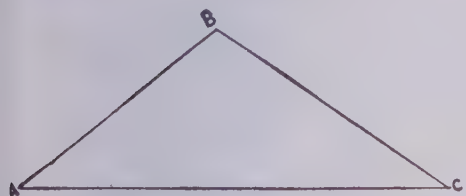
Which of the following pairs of angles are supplementary? How do you know?



(a)	45°	135°	(d)	18°	148°
(b)	59°	121°	(e)	99°	81°
(c)	75°	105°	(f)	176°	22°

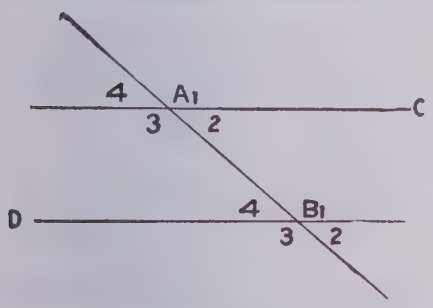
If you can get a protractor and draw these angles and measure them you will understand them much better.

In this diagram we have four right angles made by the heavy lines. Each right angle is divided into two parts by a light line.



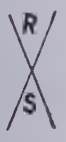
$A+B=90$
$C+D=90$
$E+F=90$
$G+H=90$

Two angles whose sum is 90° are *complementary.*



This figure is a triangle. If you measure its three angles and add them the total is 180. The sum of the angles of any triangle is 180 degrees.

$$A+B+C=180$$



This figure is a stripe cut by a transversal. The lines CA and DB are parallel. that is they go in the same direction. AB is a transversal which cuts the two parallels. Eight angles are formed. $A_1+A_2=$ how many degrees? If you cannot answer reread the paragraph about supplementary

angles. You will find that ① $A_1+A_2=180°$ ② $A_3+A_4=180°$. ③ $B_1+B_2=180°$, ④ $B_2+B_3=180°$. Are there other pairs of supplementary angles?

Look at A_1 and A_3. They are equal because their sides are the same lines. Such angles as these, such as $\angle R$ and $\angle S$ in

this small diagram are *vertical* angles. Vertical angles are equal. Returning to the diagram of the stripe, A_1 and B_1 have their sides going in the same direction and are equal. $A_2=B_2$, and $A_3=B_3$ for the same reason.

We can sum this all up in these three statements, calling angles marked 1 and 3 odd, and 2 and 4 even. In a stripe:

① The four odd angles are equal

② The four even angles are equal

③ One odd added to one even angle makes 180 degrees.

These facts about angles will give us many interesting problems to solve.

PROBLEM 4. One of the angles in a stripe is 8 times another. How many degrees in each?

Let $x=$the number of degrees in the smaller angle.

Then $8x=$the number of degrees in the larger angle.

①	$x+8x=180$	
②	$9x=180$	
③	$x=20$	②÷9
④	$8x=160$	③×8

Check 20 + 160 = 180 — *Ans.* 20° and 160°

You can now make such problems, for yourself, and solve them.

PROBLEM 5. In the triangle $A\ B\ C$ angle B is twice angle A, and angle C is 3 times A. Find the angles.

Let $x=$no. of degrees in $\angle A$.
Then $2x=$no. of degrees in $\angle B$.
And $3x=$no. of degrees in $\angle C$.

Now we know that the sum of three angles of a triangle is 180 degrees, therefore

①	$x+2x+3x=180$	
②	$6x=180$	
③	$x=30$	②÷6
④	$2x=60$	③×2
⑤	$3x=90$	③×3

Check 30 + 60 + 90 = 180 — *Ans.* $A=30°$, $B=60°$, $C=90°$.

PROBLEM 6. In paying \$68, I used only \$5 and \$2 bills. The number of \$5 bills was 3 times the number of \$2 bills. How many of each?

Let $x=$the no. of \$2 bills
Then $3x=$the no. of \$5 bills

Now we cannot add the number of *bills* and get the number of *dollars*. Think this over carefully. If you count the number of bills in a pile, do you know how many dollars the pile is worth? Does it make a difference whether the bills are ones or twos or fives or tens? Seven \$5 bills make how much money? 10, \$5 bills? x, \$5 bills? The answers to these three questions are found by multiplying five by seven, five by ten and five by x. The answers are \$35, \$50 and $5x$ dollars. How many dollars in 8 \$2 bills? in 20 \$2 bills? in 3 \$2 bills?

Ans. \$16, \$40 and \$6.

Now look back at our problem. How many dollars in x\$2 bills? Answer $2x$ dollars. How many dollars in $3x$\$5 bills? Answer $15x$ dollars. The next two lines of our solution will be

$2x=$the no. of dollars in \$2 bills.
$15x=$the no. of d llars in \$5 bills.

Now we are ready to add *dollars* and find the number of dollars in all.

① $2x+15x=68$

Because the problem says there were 68 dollars in all.

②	$17x=68$	
③	$x=4$	②÷17
④	$3x=12$	③×3

Check 4 \$2 bills = \$ 8; 12 \$5 bills = 60; 68 — *Ans.* 4 \$2 bills, 12 \$5 bills

PROBLEM 7. To pay \$168 I use \$10 and \$2 bills only, 4 times as many 10's as 2's. How many of each?

Let $x=$the number of \$2 bills.
Then $4x=$the number of \$10 bills.
$2x=$the number of dollars in 2's.
$40x=$the number of dollars in 10's.
$2x+40x=$the number of dollars in all.
But $168=$the number of dollars in all, therefore.

①	$2x+40x=168$	
②	$42x=168$	
③	$x=4$	②÷42
④	$4x=16$	③×4

Check 4 2's = \$ 8; 16 10's = 160; 168 — *Ans.* 4, 2's; 16, 10's

The next problem does not read at all like problems 6 and 7 but it really is the same kind.

PROBLEM 8. A dealer sold out his stock of used Fords at \$430 each and Buicks at \$920 each. There were 3 times as many Fords as Buicks. He received in all \$15470. How many cars of each kind did he sell?

Let $x=$the number of Buicks sold.
Then $3x=$the number of Fords sold.

$920x=$the number of dollars received for the Buicks.

$1290x=$the number of dollars received for the Fords.

The $1290x$ was found by multiplying $3x$, the number of Fords, by 430, the number of dollars each Ford sold for.

①	$920x+1290x=15470$	
②	$2210x=15470$	
③	$x=7$	②÷2210
④	$3x=21$	③×3

Check 7 Buicks at 920 = 6440; 21 Fords at 430 = 9030; 15470 — *Ans.* 7 Buicks, 21 Fords

PROBLEM 9. A bookseller shipped dictionaries weighing $7\frac{1}{2}$ pounds each and 6 times as many algebra books weighing 2 pounds each.

The total weight of the shipment was 195 pounds. How many books of each kind?

Let $x=$the no. of dictionaries.
Then $6x=$the no. of algebras.
$7\frac{1}{2}x=$the no. of pounds the dictionaries weighed.

$12x=$the no. of pounds the algebras weighed.

Why is it $12x$? Because there are $6x$ algebras at 2 pounds each.

①	$7\frac{1}{2}x+12x=195$	
②	$19\frac{1}{2}x=195$	
③	$x=10$	②÷19½
④	$6x=60$	③×6

Check
10 dictionaries at $7\frac{1}{2}$ lb. = 75 lb.
60 algebras at 2 lb. = 120
195 lb.

Ans.
10 dictionaries
60 algebras

One more for you to solve. You can make more problems for yourself about bills or coins; or find them in Evans and Marsh, First Year Mathematics.

PROBLEM 10. To pay \$245 use \$20 and \$5 bills only. Three times as many 5's as 20's. How many of each?

SECOND KIND OF EQUATION

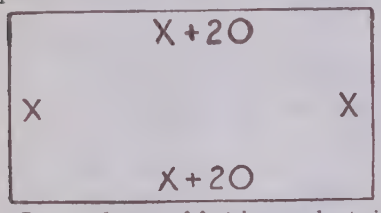
PROBLEM 11. One angle of a stripe is 8 degrees more than the other. Find the number of degrees in each angle.

Let x = the no. of degrees in the smaller angle.

Then $x+8$ = the no. of degrees in the larger angle.

To find a number 8 larger than x, we must add 8 to x. This gives us $x+8$.

① $x+x+8=180$



② $2x+8=180$

This equation cannot be solved by the steps we have been taking. What is the difficulty? Clearly the "8" is in the way. How can we remove it without making our equation untrue? If we have eight too much, the remedy must be to *subtract* eight.

③	$2x=172$	②−8
④	$x=86$	③÷2
⑤	$x+8=94$	④+8

Check	*Ans.*
86°	86°, 94°
94°	
180°	

PROBLEM 12. The perimeter of a rectangle is 136 feet. One side is 20 feet shorter than the other. Find the length of each side. The diagram shows a rectangle. Each of its angles is a right angle. You notice that the two short sides are equal, and the two long sides are equal. The perimeter is the sum of the four sides.

Let x = the no. of feet in one short side.

Then $x+20$ = the no. of feet in a long side.

Adding the four sides to get the perimeter we get $x+x+20+x+x+20$. Uniting these we get $4x+40$. Therefore

①	$4x+40=136$	
②	$4x=96$	①−40
③	$x=24$	③÷4
④	$x+20=44$	④+20

Check	*Ans.*
24	24 feet
44	44 feet
24	
44	
136	

PROBLEM 13. Solve problem 12 in case the perimeter was 150 feet, and one side was 35 feet shorter than the other. Answer 20 ft. and 55 ft.

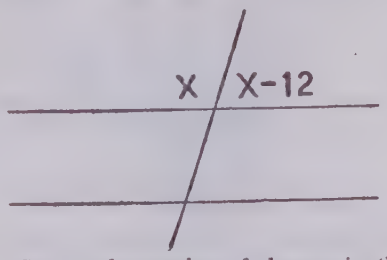
Make many more of these problems and solve them.

PROBLEM 14. I sold canned corn at 11 cents a can and 5 times as many cans of tomatoes at 14 cents each, and one can of peas at 12 cents. If the total receipts were $4.98, how many cans of corn and tomatoes did I sell?

Let x = the no. of cans of corn.

Then $5x$ = the no. of cans of tomatoes.

$11x$ = the no. of cents for the corn.



$70x$ = the no. of cents for the tomatoes—because there were $5x$ cans at 14 cents a can.

①	$11x+70x+12=498$	
②	$81x+12=498$	
③	$81x=486$	②−12
④	$x=6$	③÷81
⑤	$5x=30$	④×5

Check	*Ans.*
6 cans corn at .11 = $ .66	6 cans corn.
30 cans tom. at .14 = 4.20	30 cans tomatoes.
1 can peas at .12 = .12	
$4.98	

THE THIRD KIND OF EQUATION
SHORTAGES

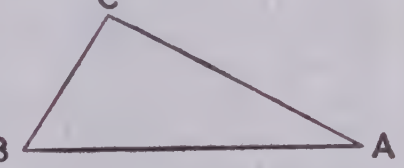
PROBLEM 15. If one angle of a stripe is 12 degrees less than another angle of the same figure, fin the number of degrees in each angle.

Let x = the number of degrees in the larger angle.

Then $x-12$ = the no. of degrees in the smallerrangle—because 12 taken away from x gives $x-12$. This is read x less 12 or x minus 12.

① $x+x-12=180$

Because the sum of 2 angles of a stripe is 180°.



② $2x-12=180$

None of the steps we have taken so far will solve this equation. What is the difficulty? We are short 12. The left hand side is 12 less than $2x$. If it was just $2x$ we could go ahead. How can we make it just $2x$? By *adding* 12.

③	$2x=192$	②+12
④	$x=96$	③÷2
⑤	$x-12=84$	④−12

Check	*Ans.*
96°	96°, 84°
84	
180	

PROBLEM 16. The $\angle B$ of a triangle is double the $\angle A$, and $\angle C$ is 30 degrees less than the sum of A and B. How many degrees in each angle?

Let x = the no. of degrees in A.

Then $2x$ = the no. of degrees in B.

And $3x-30$ = the no. of degrees in C.

Because the sum of $\angle A$ and $\angle B$ is $3x°$. Thirty degrees less is $3x-30$.

But the sum of the three angles of a triangle is 180°.

①	$x+2x+3x-30=180$	
②	$6x-30=180$	
③	$6x=210$	②+30
④	$x=35$	③÷6
⑤	$2x=70$	④×2
⑥	$3x-30=75$	④+(5)−30

Check	*Ans.*
35	$A=35°$, $B=70°$, $C=75°$
70	
75	
180	

Problems like 11 and 12 will give equations of this kind if you let x stand for the *larger* number. Try them.

The Convenience of the Parenthesis in an Equation

PROBLEM 17. I paid $1.45 with nickels and dimes using 7 less nickels than dimes. How many of each?

Let x = the number of dimes.

Then $x-7$ = the number of nickels.

$10x$ = the number of cents in dimes.

$5(x-7)$ = the number of cents in nickels.

The ( ) is a parenthesis. A parenthesis is used to tie two or more terms together to show that they are all to be treated alike. Think of it as a string tieing together the terms inside. The parenthesis containing the $x-7$ merely tells us that the x and the minus 7 are to be treated alike. The 5 in front of the parenthesis means that both the x and the minus 7 are to be *multiplied* by 5. To read an expression with a parenthesis in it merely read "'5 times the parenthesis $x-7$" or "five times the quantity $x-7$."'

① $10x+5(x-7)=145$. Because this is the number of cents in all.

We will now carry out the instructions in the expression $5(x-7)$, namely multiply the $x-7$ by 5.

② $10x+5x-35=145$

Why is it *Minus* 35. Because we are short 7 five times, that is we are short 35 in all.

③	$15x-35=145$	
④	$15x=180$	③+35
⑤	$x=12$	④÷15
⑥	$x-7=5$	⑤−7

Check	*Ans.*
12 dimes = $1.20	12 dimes
5 nickels = .25	5 nickels
$1.45	

PROBLEM 18. John is twice as old as Will. Eighteen years ago John was five times as old as Will. How old are they?

Let x = the no. of years in Will's age now.

Then $2x$ = the no. of years in John's age now.

The next quantities we must list are their ages 18 years ago. If a man is 38 now how old was he 18 years ago? To answer you must *subtract* 18, therefore

$x-18$ = the no. of years in Will's age 18 years ago.

$2x-18$ = the no. of years in John's age 18 years ago.

But John was then 5 times as old as Will. This gives us the equation

① $5(x-18)=2x-18$

Now multiply both x and minus 18 by 5.

② $5x-90=2x-18$

We now have a shortage on each side of the equation. We must get rid of both of them. How? By adding the larger shortage, that is 90. Try it.

③ $5x=2x+72$ ②+90

Where did we get the 72? We were short 18 and added 90. If the thermometer stood at −18 and rose 90 where would it stand? If you owed a man $18 and you worked for him until you had earned 90, how much should he pay you to balance the accounts? Equation three might be written first in the form ③ $5x+90-90=2x+90-18$ then reduced to $5x=2x+72$.

There is another difficulty in ③. There is a term with x in it in *each* side. We want x on one side and a number on the other. The $2x$ is in the way. How can we get rid of it?

We must *subtract* $2x$.

④	$3x=72$	③−2x
⑤	$x=24$	④÷3
⑥	$2x=48$	⑤×2

Check			*Ans.*
NOW	18	Y's AGO	
Will	24	6	Will is 24
John	48	30	John is 48
24×2=48		6×5=30	

Do you understand the check? Is John twice as old as Will now? Eighteen years ago was he 5 times as old?

PROBLEM 19. A father is twice as old as his son. Twenty-two years ago he was 3 times as old. How old are they now?

Let x = the no. of years in son's age now.
Then $2x$ = the no. of years in father's age now.
$x-22$ = the no. of years in son's age 22 years ago.
$2x-22$ = the no. of years in father's age 22 years ago.

① $3(x-22)=2x-22$
② $3x-66=2x-22$
③ $3x=2x+44$ ②+66
④ $x=44$ ③−$2x$
⑤ $2x=88$ ④×2

Check *Ans.*

NOW	22 Y's AGO	Father 88 years
Father 88	66	Son 44 years
Son 44	22	

$22\times3=66$

PROBLEM 20. Apples cost 15 cents a dozen less than oranges. If 2 dozen apples and 3 dozen oranges cost $1.65, what is the cost of a dozen of each?

Let x = the no. cents for 1 doz. oranges.
Then $x-15$ = the no. cents for 1 doz. apples.
$3x$ = the no. cents for 3 doz. oranges.
$2(x-15)$ = the no. cents for 2 doz. apples.

① $3x+2(x-15)=165$
② $3x+2x-30=165$
③ $5x-30=165$
④ $5x=195$ ③+30
⑤ $x=39$ ④÷5
⑥ $x-15=24$ ⑤−15

Check *Ans.*

2 doz. at .24 = $ .48	Oranges $.39 a doz.
3 doz. at .39 = 1.17	Apples .24 a doz.
1.65	

We will now take some *equations* to practice on. They have been made from problems but just what the problems are we do not know.

Exercise 1

① $13(8-x)+2(x-6)=2x+1$

The first thing to do is to do the multiplying indicated by the parentheses. (Notice how the plural of this word is spelled.)

② $104-13x+2x-12=2x+1$

The next step is to unite the similar terms. $104-12$ gives 92. Short $13x+2x$ leaves us short $11x$.

③ $92-11x=2x+1$

The next step is to remove the shortage by adding $11x$.

④ $92=13x+1$ ③+$11x$

Which term is in the way now? Clearly the "one" because we want x on one side and a number on the other. Therefore take away the number which stands on the same side as the x term.

⑤ $91=13x$ ④−1

To find x we must divide by 13.

⑥ $7=x$ ⑤÷13

Ans. 7

Since there is no problem to check in, in order to discover whether our answer is correct, we must check in ①.

The only kind of a sentence that has an answer is a question. Equation one has an answer therefore it is a question, even though it is written without any question mark. What is the question? It is this. How big is x if $13(8-x)+2(x-6)$ equals $2x+1$.

Our solution indicates that 7 is the answer to this question. Let us see if 7 does make these two quantities equal.

① $13(8-x)+2(x-6)=2x+1$

Supposing x to be 7 we get:

$13(8-7)+2(7-6)=14+1$
$13(1)+2(1)=15$
$13+2=15$
$15=15$

Therefore 7 is the number which makes these two quantities equal. Try all the other numbers you want to. There is no other number which will do.

Exercise 2

① $15(7x-3)=8(13x+7)-20$
② $105x-45=104x+56-20$
③ $105x-45=104x+36$
④ $105x=104x+81$ ③+45
⑤ $x=81$ ④−$104x$

Check *Ans.*

$15(567-3)=8(1053+7)-20$ 81
$15(564)=8(1060)-20$
$8460=8480-20$
$8460=8460$

The parts of an equation which are separated by plus or minus signs are called *terms*. Any term with an x in it is called an x-term.

The steps to take in solving such simple equations as these are:

(1) Perform any indicated multiplications.

(2) Unite similar terms on each side.

(3) If there are any terms with minus signs before them, add enough to make up these shortages.

(4) Subtract from each side the smaller x-term.

(5) Subtract from each side the number that stands beside an x-term.

(6) Divide by the coefficient of the x-term.

You can see for yourself what the long word coefficient means. In exercise 1, the last history was ⑤÷13. In ⑤ the 13 is the coefficient of the x.

Rule (3) is interesting because the arabic word for this step is the source of the word Algebra from which our subject takes its name.

These rules were first formulated for modern students in the Evans & Marsh, First Year Mathematics, Merrill, which you will find very helpful in the further study of Algebra.

Try these exercises, thinking *first* which step you are going to take to meet the difficulty before you.

3. $3(x-7)=2x-11$
4. $2(x+5)=10x-6$
5. $2x+5=3x$
6. $5x-7=3(x+1)-4$
7. $7(x-2)=4(x-4)$
8. $6x=7(10-x)$
9. $8(x+10)=12(x+7)-8$
10. $5(x+4)=14x+2$

Try these problems, looking back, if necessary, to previous models.

PROBLEM 21. One angle of a stripe is seven less than twice the other. Find the number of degrees in each.

PROBLEM 22. Sugar costs 34 cents a pound less than tea. Ten pounds of sugar and 6 of tea cost $3.32. Price of each?

PROBLEM 23. Twenty-one coins, quarters and halves amount to $8.50. How many of each?

Let x = the no. of quarters.

What will stand for the number of halves? There are 21 coins in all x of them are quarters. How many does that leave for the halves?

If you cannot answer, imagine that x is 15. If there are 21 coins in all and 15 of them are quarters, how many are halves. Clearly $21-15$. If x of them are quarters there will be $21-x$ halves.

$21-x$ = the no. of halves.
$25x$ = the no. of cents in quarters.
$50(21-x)$ = the no. of cents in halves.

① $25x+50(21-x)=850$
② $25x+1050-50x=850$
③ $1050-25x=850$
④ $1050=850+25x$ ③+$25x$
⑤ $200=25x$ ④−850
⑥ $8=x$ ⑤÷25
⑦ $13=21-x$ 21−⑥

Check *Ans.*

8 quarters = $2.00	8 quarters
13 halves = 6.50	13 halves
$8.50	

PROBLEM 24. Sixteen coins, quarters and dimes amount to $2.95. How many of each?

PROBLEM 25. Forty pounds of tea, part costing 32 cents a pound and part 44 cents a pound come to $15.32. How many pounds of each?

HOW TO FORM AN EQUATION

One of the difficulties in solving the problems of algebra is the construction of the equation. Study of the problems we have solved shows that the steps to take are three. First make a list of the numbers talked about in the problem but not actually given in figures. Second select one of them to be represented by x and then represent the others according to their relations to this first one. Third, when this has been done make a statement that two things are equal, either by using some statement of the problem not used in making the list, or by using two abbreviations for the same number in the list.

Study of the models and of your problems with these three rules in mind will make the formation of equations easier.

Another great help is this: when the answer to a problem is found go over each statement of the problem very carefully to see if the answer meets every condition of the problem. This not only checks the accuracy of the answer but it makes clear the steps you took in forming your equation. Check the answer to every problem.

FRACTIONAL EQUATIONS

The next problems will give us equations with fractions. Suppose we have the equation

$$① \quad \frac{x}{2}=9$$

how shall we solve it? If x over 2 or $\frac{1}{2}x$ equals 9, how much is the whole of x? We must multiply by 2.

② $x=18$ ①×2

This then is the key to all fractional equations.

Exercise 1

$$① \quad \frac{x}{5}=8$$

② $x=40$ ①×5

PROBLEM 26. One half of a certain number and one fifth of it make 28. What is the number?

Let x = the number.

$\frac{x}{2}$ = one half the number.

$\frac{x}{5}$ = one fifth the number.

The statement in our problem which we have not used in our list is that one half the number and one fifth the number equal 28. Saying this fact and using the expression in our list we get,

$$① \quad \frac{x}{2}+\frac{x}{5}=28$$

This is read x over 2 plus x over 5 equals 28.

We can take care of the $\frac{x}{2}$ by multiplying by 2.

$$② \quad x+\frac{2x}{5}=56 \qquad ①\times 2$$

We can take care of the $2x$ by multiplying by 5.

$$\begin{array}{ll} ③\ 5x+2x=280 & ②\times 5 \\ ④\ \ 7x=280 & ③\text{ same values} \\ ⑤\ \ x=\ 40 & ④\div 7 \end{array}$$

Check	*Ans.*
One half of $40=20$	40
One fifth of $40=\ 8$	
28	

PROBLEM 26A. Two thirds of a number added to four sevenths of it make 520. What is the number?

Let x = the number.

$\frac{2x}{3}$ = two-thirds of the number.

This may be written $\frac{2}{3}x$ or $\frac{2x}{3}$. The first is read "two thirds x;" the second "two x over three."

$\frac{4x}{7}$ = 4/7 of the number.

$$① \quad \frac{2x}{3}+\frac{4x}{7}=520$$

Instead of multiplying first by 3 and then by 7, what one number can we multiply by? Twenty-one of course.

$$② \quad 14x+12x=10920 \qquad ①\times 21$$

To be sure of each term as you multiply, set it down.

$$\frac{2x}{3}\times 21=14x, \quad \frac{4x}{7}\times 21=12x$$

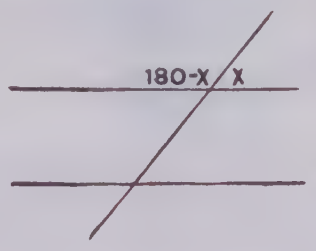
$$\begin{array}{ll} ③\ 26x=10920 & ③\div 26 \\ ④\ \ x=\ 420 & \end{array}$$

Check	*Ans.*
2/3 of $420=280$	420
4/7 of $420=240$	
520	

PROBLEM 27. One line is 3 times another, and half the shorter line is 20 in. less than the longer line. Find the length of each line.

Let x = the no. of inches in length of shorter line.

Then $3x$ = the no. of inches in length of longer line.



$\frac{x}{2}$ = the no. of inches in half of shorter line,

The fact not used in making our list is that "half the shorter is 20 in. less than the longer." To say this fact using the word "equals" we may write, half the shorter equals the longer less 20 inches. Say the same thing using the expressions in our list.

$$\begin{array}{ll} ① \quad \frac{x}{2}=3x-20 & \\ ② \quad x=6x-40 & ①\times 2 \\ ③\ \ x+40=6x & ②+40 \\ ④\ \ \ 40=5x & ③-x \\ ⑤\ \ \ \ 8=x & ④\div 5 \\ ⑥\ \ 24=3x & ⑤\times 3 \end{array}$$

Check	*Ans.*
½ of $8=4$	8 inches
4 is 20 less than 24	24 inches

PROBLEM 28. In the figure formed by a stripe and a transversal one half the smaller angle equals two-fifths of the larger angle. How many degrees in each angle?

Let x = the number of degrees in the smaller $\angle$.

How shall we represent the number of degrees in the larger $\angle$? The larger added to the smaller equals 180°. If the smaller is x the larger will be $180-x$.

$180-x$ = the no. of degrees in the larger $\angle$.

We are told that

1/2 the smaller = 2/5 the larger, that is:

$$① \quad \frac{x}{2}=\frac{2}{5}(180-x)$$

$$\begin{array}{ll} ②\ \ 5x=4(180-x) & ①\times 10 \\ ③\ \ 5x=720-4x & ②\text{ same values} \\ ④\ \ 9x=720 & ③+4x \\ ⑤\ \ \ x=\ 80 & ④-9 \\ ⑥\ 180-x=100 & 180-⑤ \end{array}$$

Check	*Ans.*
1/2 of $80°=40°$	80°
2/5 of $100°=40°$	100°

PROBLEM 29. Solve problem 28 changing it to read, one-third the smaller angle equals one-fifteenth the larger.

PROBLEM 30. One angle exceeds half of another by 10° and exceeds the complement of their sum by 30°. Find the angles.

This kind of problem often gives much trouble to beginners but if you will reread, "How to Form an Equation" on page 841 and if you will use care in making your list you will not find it hard.

Let x = the number of degrees in the second $\angle$.

The first $\angle$ exceeds half the second by 10°. That is:

$x/2+10$ = the no. of degrees in first $\angle$.

$x+x/2+10$ = the no. of degrees in the sum of the two $\angle$s.

The next quantity to set down in our list is, the complement of their sum. How do we find the complement of an angle? What is the complement of 10°, answer 90−10 or 80°; of x, answer $90-x$; of $x+x/2+10$, answer $90-(x+x/2+10)$, therefore $90-x-x/2+10$ = the no. of degrees in the complement of their sum. This completes our list and there is still one statement in the problem which we have not used. The (first) angle exceeds the complement of their sum by 30 degrees. Stating this with the word "equals" we have: The first angle equals the complement of their sum, plus 30°, which when translated from our list reads:

① $x/2+10=90-(x+x/2+10)+30$

② $x/2+10=90-x-x/2-10+30$ ① same values

Notice that the minus sign before the parenthesis told us to subtract all the terms in the parenthesis. Have we *subtracted* all three of them in ②?

③ $x+20=180-2x-x-20+60$

④ $x+20=220-3x$ ②×2

③ same values

Where do we get the $-3x$? You notice that we are *short* $2x$ and *short* x. This makes us *short* $3x$ in all.

$$\begin{array}{ll} ⑤\ 4x+\ 20=220 & ④-3x \\ ⑥\ \ \ 4x=200 & ⑤-20 \\ ⑦\ \ \ x=\ 50 & ⑥\div 4 \\ ⑧\ x/2+10=\ 35 & ⑥/2+10 \end{array}$$

Check	*Ans.*
1st $\angle=35°$	35°, 50°

438 Total

Ans.

John, $249
James, $179

Considerable practice is required to develop speed and accuracy with fractional equations.

1. $x/3+x/5+4=x-3$
2. $x/2+x/3+1/2=x-1$
3. $x/2-x/5=x/2-3$
4. $x/7-\frac{3x}{7x}=17$
5. $\frac{7x-6}{5}+\frac{-3x-5}{3}+\frac{x-1}{2}$

$$① \quad \frac{7x-6}{5}+\frac{x}{3}-\frac{3x-5}{2}=x-1 \qquad ①\times 30$$

$$\begin{array}{ll} ② & 42x-36+10x=45x-75+30x-30 \\ ③ & 52x-36=75x-105 \quad ②\text{same values} \\ ④ & 52x+69=75x \qquad ③\div 105 \\ ⑤ & 69=23x \qquad ④-52x \\ ⑥ & 3=x \qquad ⑤\div 23 \end{array}$$

Check *Ans.* 3

[Put 3 in place of x in ①]

$\frac{21-6}{5}+\frac{3}{3}=\frac{9-5}{2}+3-1$

$3+1=2+3-1$

$4=4$

6. $\frac{3x-7}{4}-\frac{3x}{11}=\frac{x-5}{2}$

7. $\frac{x+1}{2}+2+\frac{x+3}{4}=x$

8. $\frac{x-1}{7}+\frac{3x-1}{5}+\frac{1}{7}=\frac{x-7}{3}+\frac{4x-3}{5}$

9. $\frac{x-1}{2}-\frac{2}{5}-\frac{x+3}{5}=0$

① $\frac{x-1}{2}-\frac{2}{5}-\frac{x+3}{5}=0$

② $5x-5-4-(2x+6)=0$ ①×10

The parenthesis is left in ② because the two terms of the numerator of the last fraction must be both *multiplied* and *subtracted*. The minus sign before the fraction says to subtract, and our history, ①×10, says to multiply. Trying to do both of these at once often leads to errors.

③ $5x-9-2x-6=0$ ② same values

Notice that the last term is minus 6 because we are instructed to *subtract* both the $2x$ and the 6.

④ $3x-15=0$ ③ same values

⑤ $3x=15$ ④+15

⑥ $x=5$ ⑤÷3

Check *Ans.*

$\frac{5-1}{2}-\frac{2}{5}-\frac{5+3}{5}=0$ 5

$2-\frac{10}{5}=0$

$2-2=0$

10. $\frac{5x-x+7}{10}=8-\frac{1}{2}+\frac{x+1}{5}$

11. $\frac{x+5}{6}-\frac{x+1}{8}=\frac{x+3}{4}$

12. $\frac{x}{4}-\frac{x-5}{3}=\frac{x-8}{4}$

This example looks much like those above but is in fact much more troublesome.

① $\frac{x}{4}-\frac{x-5}{3}=\frac{x-8}{4}$

② $3x-(4x-20)=3x-24$ (1)×12

The quantity to be subtracted is $4x-20$; we are not told to subtract as much as $4x$, we are told to subtract 20 *less* than $4x$. Suppose it read $30-(25-20)$. This says to take from 30 a number which is 20 less than 25. This of course means from 30 take 5. The answer is 25. If we wrote $30-25$ we would be taking away too much, 20 too much because we were told to take away not 25 but 25 less 20. To correct our mistake we must *put back* the 20, and write $30-25+20$ which gives us 25, the correct answer.

③ $3x-4x+20=3x-24$ ② same values

Do you understand the +20? Study the explanation through again. We took the whole of $4x$ when we were told to take away $4x-20$. Consequently we must *put back* the 20. We took away 20 too much, then we put back the 20.

④ $-x+20=3x-24$ ③ same values

⑤ $44=4x$ ④+x+24

⑥ $11=x$ ⑤÷4

Check *Ans.*

$\frac{11}{4}-\frac{11-5}{3}=\frac{11-8}{4}$ 11

$11/4-6/3=3/4$

$11/4-2=3/4$

$11/4-8/4=3/4$

$3/4=3/4$

13. $\frac{x+5}{7}=\frac{x-4}{2}-\frac{x-5}{8}$

14. $\frac{7x-11}{45}-1=\frac{x+7}{15}-\frac{3x+1}{25}$

15. $5x+20-2(x+2)=40-4(x-15)$

① $5x+20-2(x+2)=40-4(x-15)$

② $5x+20-(2x+4)=40-(4x-60)$

① same values

We keep the parentheses in order to avoid the mistakes which come from trying to multiply and subtract at the same time.

③ $5x+20-2x-4=40-4x+60$

② same values

Why do we write -4, and $+60$? The $2x$ and 4 are *both* to be subtracted. In the last parenthesis however we are told to take away 60 less than $4x$. When we wrote $-4x$ we took away 60 too much. Then we *put back* the 60.

④ $3x+16=100-4x$ ③ same values

⑤ $7x+16=100$ ④+$4x$

⑥ $7x=84$ ⑤−16

⑦ $x=12$ ⑥÷7

Check *Ans.*

$60+20-2(14)=40-4(-3)$ 12

$80-28=40-(-12)$

Notice the last parenthesis. This is the strangest of all the subtraction cases. We are told to take away minus 12 from 40. Taking away minus 12 is the same as taking away a *debt* of 12, that is the same as adding twelve.

⑧ $80-28=40+12$

⑨ $52=52$

A rule is sometimes stated in algebra as follows: To remove any term from a minus parenthesis change its sign. This is a dangerous rule for two reasons. First because the "change of sign" seems to have something to do with the parenthesis while it really has to do instead with the subtraction which the *minus* sign before the parenthesis tells us to perform. Second because signs do not "change" in algebra and such statements lead us to think of algebra as a kind of juggling instead of something which we can reason out for ourselves. Never use such a rule unless you can tell definitely *why* you put down the plus or the minus sign.

16. $5(x-6)-110=-17-2(x-5)$

17. $2+x+3/5-2x-13/11=x/3$

18. $\frac{8x-3}{7}-\frac{4x-7}{5}=5x-13$

Problems of Rate, Time, and Distance

PROBLEM 33. A man can ride 11 miles per hour and walk 3 miles per hour How long will it take him to go 168 miles if he walks half the time and rides half the time.

Before trying to solve this problem we must understand the simple relation connecting rate, time, and distance. One of the tasks of algebra is to use the formulas which show the relations of such quantities.

If a man walks $3mi/h$ (this is read, three miles per hour) for 5 hours what distance does he walk? Clearly 5 times 3 or 15 miles. In general, the number of hours times the number of miles per hour gives the total number of miles. The *time* multiplied by the *rate* equals the distance. Stated in the symbols of algebra, $TR=D$.

You will notice that TR means T times R just as $5x$ means 5 times x. This equation may be transformed as follows:

① $TR=D$

② $T=D/R$ ①÷R

③ $R=D/T$ ①÷T

All three equations state the same relation but from different points of view. In studying such formulas it is important to be able to see all three of these facts by looking out any ONE of them. If time times rate equals distance, then time equals distance divided by rate, and rate equals distance divided by time.

One mistake to avoid. Do not try to *learn* these formulas. Learn to make up the formula from a simple illustration just as is done on this page.

Now reread these paragraphs thoughtfully, then reread the problem and we will solve it.

	T	R	D
WALKING	$\frac{X}{2}$	3 MI/H	$\frac{3X}{2}$
RIDING	$\frac{X}{2}$	11 MI/H	$\frac{11X}{2}$
TOTAL			168 MI.

Make a table and fill in the squares one at a time, beginning with the ones we know most about. In this case the R column can be filled in first, since we know both rates; and the total D is 168 miles.

Next we must decide on what x is to stand for.

Let x=the no. of hours it takes him to go 168 miles. Then $x/2=1/2$ the time, that is, the no. of hours he walks. We can now fill in the T column. The rest is easy because whenever we know two numbers in one *row* we can find the third by one of the three formulas.

This time we use $TR=D$.

The last step is to form an equation.

The D he walks plus the D he rides is the total D.

① $3x/2+11x/2=168$

② $3x+11x=336$ ① ×2

③ $14x=336$ ② same values

④ $x=24$ ③ ÷14

Check

12 h. at $3mi/h=$ 36 mi.

12 h. at $11mi/h=132$

168

Ans.

24 hours

12 hours riding and 12 hours walking.

PROBLEM 34. A boy can ride on his wheel 10 miles per hour and walk 4 miles per hour. How long will it take him to go 126 miles if he rides half the time and walks half the time? *Ans.* 18 hours.

PROBLEM 35. Soldiers can hike an average of 2 3/4 miles per hour, trucks transport them 13 miles per hour. How long will it take a regiment to cover 115 miles if they walk 1/3 of the time and ride in trucks 2/3 of the time?

	T	R	D
HIKING	$\frac{X}{3}$	2¾	$\frac{11X}{12}$
RIDING	$\frac{2X}{3}$	13	$\frac{26X}{3}$
TOTAL			115 MI.

The order of filling in the spaces is the same as in problem 33.

Notice the $D-$ hiking space. $x/3$ must be multiplied by $2\ 3/4, x/3 \times 11/4 = 11x/12$.

① $11x/12+26x/3 = 115$
② $11x+104x = 1380$ ① $\times 12$
③ $115x = 1380$ ② same values
④ $x = 12$ ③ $\div 115$

Check
4 h. at $2\ 3/4$ *mi/h* = 11 mi.
8 h. at 13 *mi/h* = 104
115

Ans.
12 hours
4 hours hiking
8 hours riding

PROBLEM 36. A boy has $3\frac{1}{2}$ hours for exercise: how far can he ride with his father, at the rate of 21 miles per hour, before getting out to walk back, if he walks $3\frac{1}{2}$ miles per hour?

	T	R	= D
WALKING	$\frac{2X}{7}$	$3\frac{1}{2}$ MI/H	X
RIDING	$\frac{X}{21}$	21 MI/H	X
TOTAL	3½H		

The known numbers go in first: they are the R's and the total T.

Let x = the no. of miles he can ride. The number of miles he must walk back will be the same.

To fill in the T column we use the formula that $T = D/R$. (Can you get this from the formula at the top of the table?)

$T-$walking will be $\frac{x}{3\frac{1}{2}}$. $T-$riding will be $x/21$.

The fraction $\frac{x}{3\frac{1}{2}}$ is rather clumsy. Write it $\frac{x}{\frac{7}{2}}$. It is still clumsy. We would like to get rid of the 2 in the denominator. How? Multiply the numerator and denominator by 2. $\frac{x}{\frac{7}{2}} \times \frac{2}{2} = \frac{2x}{7}$.

(Notice that the sign ≡ may be used when it is convenient, to show that two expressions are actually the same, though written in different form. This equation is not an equation to be solved. The right side is merely the left side simplified. Such equations are called *identities*.)

This completes the table. It remains to find an equation.

The time walking plus the time riding = the total time.

① $2x/7+x/21 = 3\frac{1}{2}$
② $12x+2x = 147$ ① $\times 42$
③ $14x = 147$ ② same values
④ $x = 10\frac{1}{2}$ ③ $\div 14$

Check
$10\frac{1}{2}$ mi. at 21*mi/h* take $\frac{1}{2}$ hour
$10\frac{1}{2}$ mi. at $3\frac{1}{2}$*mi/h* take 3 hours
$3\frac{1}{2}$ hours

Ans.
$10\frac{1}{2}$ miles

PROBLEM 37. A certain river flows one mile per hour. A fisherman finds that he can row upstream a few miles in 3 hours, but it takes him only one hour and 48 minutes to come back. How fast can he row in still water?

	T	R	= D
DOWN STREAM	1⅘H	X+1	9/5(X+1)
UP STREAM	3H	X-1	3(X-1)

The known numbers are the $T-$upstream and the $T-$downstream. The one hour and 48 min. may better be written 1 4/5 h.

Let x = the no. *mi/h* he rows in still water.

What then is the $R-$downstream? He rows through the water x miles per hour, and the current carries him along 1 mile per hour. His rowing and the current together carry him $x+1$ miles per hour.

Going upstream however the current carries him *back* one mile every hour. His rate will be $x-1$ miles per hour.

How can we fill in the D column? $D = TR$. $D-$upstream is $9/5(x+1)$. $D-$downstream is $3(x-1)$.

What fact will give us an equation?
Distance downstream = distance back.

① $9/5(x+1) = 3(x-1)$
② $9(x+1) = 15(x-1)$ ① $\times 5$
③ $9x+9 = 15x-15$ ② same values
④ $24 = 6x$ ③ $+15-9x$
⑤ $4 = x$ ④ $\div 6$

Check *Ans.*
$R-$upstream is $(4-1)$*mi/h* 4 *mi/h*
$R-$downstream is $(4+1)$*mi/h*
3*h* at 3 *mi/h* = 9*mi*
9/5 at 5 *mi/h* = 9*mi*

PROBLEM 38. A stream flows 4 miles per hour. A boat goes downstream for an hour and takes 3 hours to get back. How fast does the boat go in still water?

PROBLEM 39. A man rows 5 miles per hour in still water. It takes him 5 hours to row upstream a certain distance and only 4 hours to return. How fast does the current flow?

	T	R	= D
DOWN	4H	5+X	4(5+X)
UP	5H	5-X	5(5-X)

What are the known numbers?
$T-$downstream and upstream. Let x = the no. *mi/h* the stream flows.

How fast can the man go downstream? Five miles an hour by rowing, plus x miles an hour which the stream carries him. His rate upstream is five *mi/h* which he rows, minus x*mi/h* which the stream carries him back. Some pupils who try to do algebra problems without thinking do not know whether to write $x-5$ or $5-x$. Ask your self which is larger. If the stream flowed faster than the man rowed could he go upstream?

We now find D by the formula, as usual. $TR = D$

Next the equation: the $D-$up = the $D-$back.

① $4(5+x) = 5(5-x)$
② $20+4x = 25-5x$ ① same values
③ $9x = 5$ ② $+5x-20$
④ $x = 5/9$ ③ $\div 9$

Check *Ans.*
$R-$down = 5-5/9*mi/h* stream flows
$R-$up = 5-5/9 = 4 4/9*mi/h* 5/9*mi/h*
4*h* at 5 5/9*mi/h* = 22 2/9*mi*.
5*h* at 4 4/9*mi/h* = 22 2/9*mi*

PROBLEM 40. A boat goes 11 miles per hour in still water. It takes the boat $3\frac{1}{2}$ hours to reach a landing upstream, and only 2 hours to return. How fast does the current flow?

Problems of Ability and Time

PROBLEM 41. It takes B 12 days to do a certain piece of work which A can do in 4 days. In how many days will they do it if they work together?

Should we add the 12 days and 4 days together and answer 16 days for them both? If one man could do the work alone in 4 days would it take them both 16 days? Clearly this is not the way to proceed.

A can do what part of the work in one day? One-fourth.

B can do one-twelfth.

Let x = the no. of days for them both together.

If it takes them x days they would do each day $1/x$ of it.

For our equation: The *Part A* does in one day + the *Part B* does in one day = the part both do in one day.

① $1/4+1/12 = 1/x$
② $3x+x = 12$ ① $\times 12x$
③ $4x = 12$ ② same values
④ $x = 3$ ③ $\div 4$

Check *Ans.*
A does 1/4 each day 3 days for both
B does 1/12 each day together
Both do $1/4+1/12 = 4/12 = 1/3$

Therefore it takes them both 3 days.

PROBLEM 42. B can do a piece of work in 18 days which A can do in 15 days. How long will it take them if they work together?

PROBLEM 42. A boy can run around a block in 6 minutes. His father can walk it in 9 minutes. If they start from the same place, in opposite directions, how long before they will meet?

Let x = no. of minutes they go.

$1/6$ = *Part* of the distance boy can run in 1 minute.

$x/6$ = *Part* of the distance boy can run in x minutes.

$x/9$ = *Part* of the distance father can walk in x minutes.

If we add the *part* the boy runs and the *part* the father walks, what shall we get for the total? We shall get the whole distance. How shall we put this down in our equation? If the boy ran, say, 2/3 of the distance and the father walked 1/3, both would cover 3/3 or 1.

The *part* the boy runs + part father walks = total distance or 1.

① $x/6+x/9 = 1$
② $3x+2x = 18$ ① $\times 18$
③ $5x = 18$ ② same values
④ $x = 18/5$ ③ $\div 5$

Check *Ans.*
$18/5 \times 1/6 = \frac{3}{5}$ of distance. They will meet
$18/5 \times 1/9 = \frac{2}{5}$ of distance in 3 3/5 minutes.
1, or total distance.

PROBLEM 43. A man can walk to his office in 40 minutes, or he can ride it in10 minutes. How long will it take him if he walks half the time and rides half the time?

Let $2x$ = no. of minutes to reach office.
then x = no. of minutes he walks.
x = no. of minutes he rides.
$1/40$ = *Part* of distance he walks in one min.
$x/40$ = *Part* of distance he walks in x min.
$x/10$ = *Part* of distance he rides in x min.
The part he walks + the part he rides = the total distance or 1.

① $x/40 + x/10 = 1$
② $x + 4x = 40$ ① ×40
③ $5x = 40$ ② same values
④ $x = 8$ ③ ÷5

Check
$8 \times 1/40 = 1/5$ of distance
$8 \times 1/10 = 4/5$ of distance
1 = total distance.

Ans.
16 minutes to reach the office. 8 min. walking, 8 min. riding.

GRAPHS.

PROBLEM 44. Six horses and 11 cows cost \$810. Thirteen horses and 5 cows, at the same prices as before, cost \$1190. Find the cost of each animal.

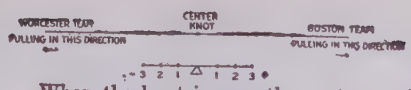
Let x = the no. of \$ for 1 horse.
It is not easy to find an expression in x for the number of dollars for 1 cow We can however, choose some other letter to stand for this number of dollars.
Let y = the no. of \$ for 1 cow.
$6x$ = the no. of \$ for 6 horses.
$11y$ = the no. of \$ for 11 cows.
From the first statement in our problem:

① $6x + 11y = 810$

From the second statement:

② $13x + 5y = 1190$

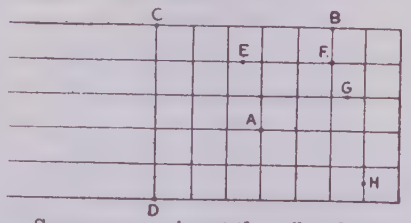
Here we are faced by new difficulties. We have two equations to start with instead of one, and each equation has two letters in it. None of the methods previously studied enable us to find the values of x and y.



Mathematicians have found a method of solving these problems by drawing lines on ruled sheets of paper. The method has proved so interesting and helpful to the mathematicians, and has been found to have so many practical applications, that it is now one of the most fascinating chapters in algebra. We will take up the method step by step, and then apply it to the solution of problem 44.

SCALES

Study the scale of a thermometer. It is numbered up to perhaps 140° at the top and down to perhaps 40° below zero at the bottom. Temperatures are usually recorded by observers as + if above zero and as − if below zero. Our scale then goes from −40° to +140°. How many degrees is this in all? It is 140° above the zero mark and 40° below the zero mark, or 180° in all.



If you compare a very large thermometer with an ordinary small thermometer you will see that the space occupied by one degree on the large thermometer may be perhaps as much as one-fourth of an inch, while on the small one it is only perhaps one sixty-fourth of an inch. Evidently we can adapt the length of our degrees to fit any particular requirements. Would you use the same scale to record the temperature of molten iron and the temperature of a fever patient? The first step in the graphical method is to draw, on our paper, a scale suited to the numbers of our problem.

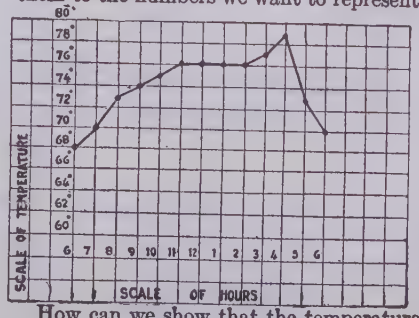
A scale could be drawn to show the changes in fortune in a tug of war.

When the knot is over the center mark neither team is ahead. When the knot is at 2, which team is ahead? Boston is, by 2 feet. When the knot is at −3 Boston is the loser by 3 feet. And so on.

Many of the cities of the United States are laid out in blocks, with streets at right angles to each other.

Suppose we arrive at the railroad station at A and ask directions to an office at B: we will be told to go 2 blocks east and 3 blocks north. What are the directions for going from A to C? Three blocks west and 3 blocks north. From A to D? Three blocks west and 2 blocks south. From A to E? Two blocks north and ½ block west. From A to F? A to G? G to H? Evidently every building in the city can be located by two numbers measured in two different directions.

The location of a ship at sea by its latitude and longitude depends upon the same idea.



It is just this principle which mathematicians have hit upon for representing facts and solving problems by charts or graphs. As soon as we have illustrated some facts on these charts we shall be ready to use them for solving our problem.

Temperatures for a summer day are observed

to be 68° at	6 A.M.	76° at	1 P.M.
70° at	7 A.M.	76° at	2 P.M.
73° at	8 A.M.	77° at	3 P.M.
74° at	9 A.M.	79° at	4 P.M.
75° at	10 A.M.	73° at	5 P.M.
76° at	11 A.M.	70° at	6 P.M.
76° at	12 M.		

Here are numbers which are changing: the hour of the day, and the temperature. We will represent the hours of the day on a horizontal scale by marking the first line of the scale 6 A.M., the second line 7 A.M. and so on for 13 lines to the right which brings us to 6 P.M.

The temperature will be represented on a vertical — that is, up and down, scale. The range to be covered is from 68° to 79°. Suppose we call the lowest line 60°, the next line above 62° and so on up to 80°. We have now completed our two scales, at right angles to each other, and adapted them to the numbers we want to represent.

How can we show that the temperature was 68° at 6 A.M.? By a dot on the 6 A.M. line just high enough up to be on the 68° line. Can you find this dot? It is the first one at the left.

Next represent a temperature of 70° at 7 A.M. by a dot on the 7 A.M. line, and just high enough up to be on the 70° line. It is the second dot going toward the right. Continue to locate the dots as shown in the figure.

If we connect these dots with a curved line we shall have a graph which will show the approximate temperature at any hour of the day.

At about what time was the temperature highest? How does our graph show this? By the highest point at 4 P.M. At what hours was the temperature changing very little if at all?

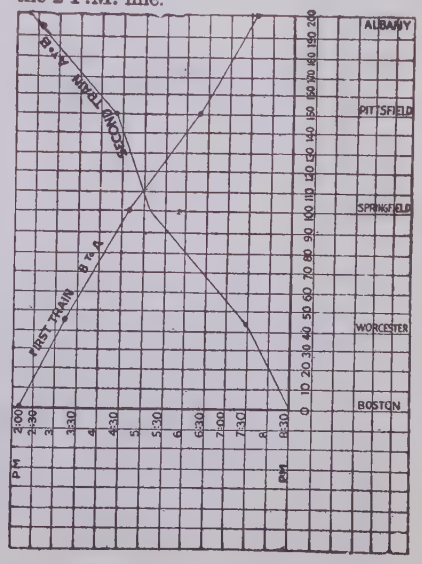
At 11, 12, 1, and 2 the temperature stood at 76°.

What was the coolest hour of the day? Six A.M. This is shown by the lowest point on the graph.

As soon as we understand a graph we can see at a glance, facts that would take us some time to discover from a study of the table from which the graph was made. It is for this reason that graphs are used increasingly in magazines and by business and professional men.

If you secure from a stationer some properly ruled paper, you can draw these graphs yourself.

The next table shows the time two Boston and Albany trains leave the stations indicated. Notice that one train goes from Boston to Albany, the other from Albany to Boston.



Miles		P.M.	P.M.
0	Boston	2:00	8:35
45	Worcester	3:15	7:25
100	Springfield	4:35	5:55
150	Pittsfield	6:20	4:18
200	Albany	7:35	2:42

The two numbers which are changing are the hour, and the number of miles from Boston. Represent the number of miles on the horizontal scale. To fit 200 miles to our scale we shall use how many miles for each space? Ten will do very nicely.

On the vertical scale we must represent the time. The range is from 2 P.M. to 8:35 P.M. or 6 hours and 35 minutes.

Let each space represent ½ hour.

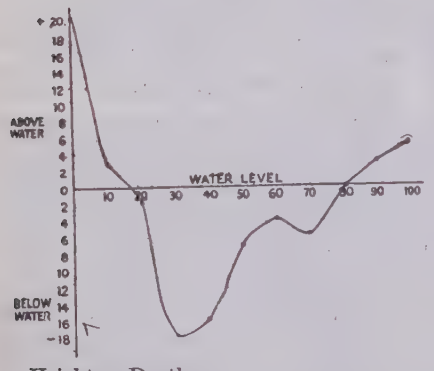
To show that the first train leaves Boston at 2 P.M., we place a dot on the Boston line and high enough up to be on the 2 P.M. line.

This is the first dot to the right. Put in all the dots and connect them.

Construct the graph for the second train in the same way.

How far from Boston do the trains meet, and at what time? The two lines cross at a point which is on, or very near the 110 mile line. This means that the trains pass about 110 miles from Boston. This same point is on, or very close to the 5 o'clock line, therefore the trains will pass at about 5 P.M.

At 6 P.M. the railroad president steps into the office and asks where each train is at that time. A clerk glances at the graphs, letting his eye follow across the 6 P.M. line. He finds the first train 140 miles from Boston: the second train 80 miles from Boston.



Several other facts can be seen immediately from the graphs after you are familiar with them. All trains from Boston to Albany will be represented by lines sloping *down* to the right: trains from Albany to Boston by lines sloping *up* to the right. The more slowly the train moves the steeper the line becomes. You will notice that the graph for the first train has the steepest slope between Springfield and Pittsfield. This is because it goes slowly between these cities because of the up grade. What similar fact can you discover concerning the second train? The fact that the slope of the graph shows the rate, leads to some very important studies farther along in mathematics.

One more illustration of the use of a graph to show facts at a glance.

Measurements are made of the height of the banks of a river and of the depth of the river, at intervals of ten feet, on a line that passes straight across the river from bank to bank.

The results are as follows, starting at the top of the left bank and making the measurements from the water level. For convenience heights *above* the water level are marked plus: depths below are marked minus.

Distance
From left to right
0 10 20 30 40 50 60 70 80 90 100

Height or Depth
+20 +3 −2 −18 −16 −7 −4 −6 0 +3 +5

The range on our horizontal scale will be 0′ to 100′. Let each space equal 5′.

The range on the vertical scale will be +20 to −18. Let each space equal 2′.

Locate the dots and connect them. This shows at a glance the approximate depth of the river at any point.

Where is the channel, or deepest part of the river? About 30 feet from the top of left bank. Where is a shallow place? About 20 feet from the right edge of the river. Which bank is the steeper?

THE SOLUTION OF PROBLEMS BY GRAPHS

If you will now reread problem 44 you will find that it gave us two equations:

① $6x+11y=810$

② $13x+5y=1190$

Each equation contains two quantities which may change in value, namely x and y. In ① if $x=124$, y will equal 6. Try it for yourself. Substitute 124 for x. $6x$ will then be 744.

③ $744+11y=810$

④ $11y=66$ ③ -744

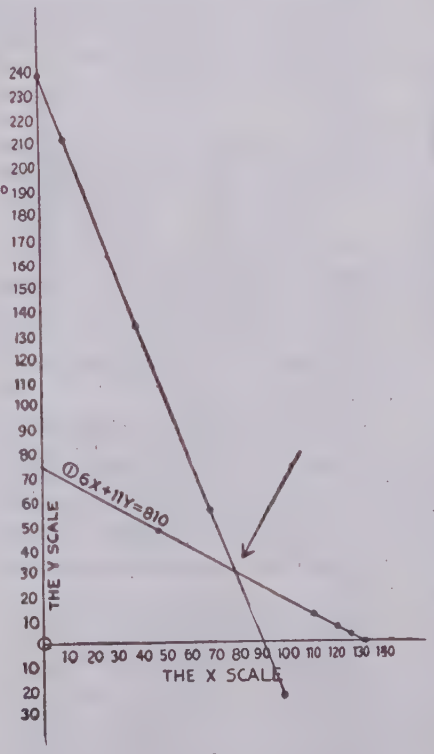
⑤ $y=6$ ④ $\div 11$

In the same way if $y=0$ in ①

⑥ $6x+0=810$

⑦ $x=135$ ⑤ $\div 6$

Substitute any number you choose in place of y and you can find a value for x For every value of x there is a corresponding value for y.



Equation one cannot be said to have an answer, but it has an unlimited number of *pairs* of *answers*. If $x=124$ and $y=6$, $6x+11y$ will equal 810. Try it. $744+66=810$.

Again if $x=135$ and $y=0$, $6x+11y$ will equal 810.

Try it $810+0=810$.

You have probably already discovered that we have just the conditions needed for a graph, namely two numbers that change together.

Make a table of values for equation one.

① x	y
0	73 7/11
135	0
129 1/2	3
124	6
113	12
47	48

The first pair was found by letting $x=0$. The second pair by letting $y=0$. The third by letting $y=3$. And so on. Make a similar table for

② x	y
0	238
91 7/13	0
10	212
40	134
70	56
100	−22

The complete range for x, in both equations, is from 0 to 135. Let each space represent 10. It is customary to represent x on the horizontal scale. The complete range for y is −22 to 238. Represent the values of y on the *vertical* scale, letting each space represent ten.

We are now ready to represent each pair of values by a dot on our chart. Take the first equation first. The first pair is 0 for x and 73 7/11 for y. Where is the 0 line for x? It is the vertical line marked 0, on which we have placed the y scale. How far upward on this line shall we go? Up to 73 7/11, that is about 1/3 of the distance from 70 to 80. Can you find this first dot?

Now the second dot, $x=135$, $y=0$. Where is the $x=135$ line? It is a vertical line midway between the numbers 130 and 140. How far upward on this line shall we go? Only to $y=0$. In other words we do not go upward at all. The dot is on the x scale line. The third dot, $x=129$ 1/2, $y=3$. This is almost over to the 130 line, and how far up? Up 3, that is about 1/3 of the distance from 0 to 10. Locate all the dots for equation ①.

Connect these dots with a line. A rather curious thing occurs. This line through all these dots is a *straight line*. It is called the graph or the locus of the equation. All such equations have straight line graphs and for this reason are called *linear* equations. (If you are not sure how to pronounce this word look it up in a dictionary).

Draw the graph of ② in the same way, locating the dots and connecting them with a line. This proves to be a straight line as we knew it would.

You have already noticed that every point on our chart can be located by two numbers, an x number and a y number, just as every building in our western city could be located by two distances, one north and one east, or one south and one west, etc., and just as every point on the surface of the earth can be located by a latitude number and a longitude number.

There is one peculiar point on our chart. The point where the two graphs cross. Can you find the two numbers which locate it? They are $x=80$ and $y=30$. Let us see just what must be true of these numbers. How many pairs of numbers will "satisfy" ①, that is make its two sides equal? All the pairs in our table and hundreds more pairs which we could have found in the same way. How many pairs of numbers will satisfy ②? Again the answer is an unlimited number. But of all these two sets of number pairs there is only *ONE* pair that will satisfy both equations, namely 80 and 30.

Try these two numbers in both equations.

① $6(80)+11(30)=810$
$480+330=810$
$810=810$

② $13(80)+5(30)=1190$
$1040+150=1190$
$1190=1190$

These two numbers are the answers to our two equations, and consequently the answers to our problem.

Look back to problem 44 and see if they will check.

6 horses at $80 cost	$480
11 cows at $30 cost	330
Total	$810
13 horses at $80 cost	$1040
5 cows at $30 cost	150
Total	$1190

Ans.
$80 for each horse
30 for each cow

The explanation of this problem has surely been long enough, but you will not wonder at it when you learn that college students often spend a year's time studying these graphs, and that our great statistical organizations have scores of clerks at work all the time making such graphs for the use of factories and business house.

PROBLEM 45. A farmer pays 6 men and 8 boys $32 for a day's work. The next day, paying the same wages, he pays 10 men and 2 boys $42 for the day's work. How much does he pay a man? A boy?

Let x = no. of $ for a man per day
Let y = no. of $ for a boy per day
① $6x+8y=32$
② $10x+2y=42$
A table of pairs of values for ①;
First let $x=0$, then how much is $6x$?
$6x=0$ and ① becomes $8y=32$. Divide by 8, $y=4$.
Next let $y=0$, $6x$ will equal 32, and x will equal 5 1/3
If we subtract $8y$ from ① it will read $6x=32-8y$
Dividing by 6 we get $x=\frac{32-8y}{6}$ or $x=\frac{16-4y}{3}$

①

x	y
0	4
5 1/3	0
2 2/3	2
1 1/3	3

①

X	Y
0	4
5⅓	0
2⅔	2
1⅓	3

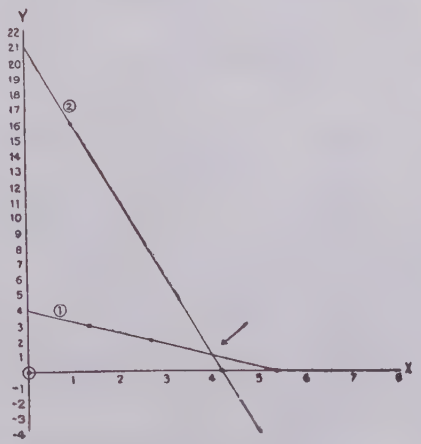
Now substitute any number for y and it will be very easy to find the corresponding value of x.

If $y=2$, $x=\frac{16-8}{3}=2\ 2/3$
If $y=3$, $x=1\ 1/3$
A table of pairs of values for ②

② $10x+2y=42$
③ $2y=42-10x$ ②$-10x$
④ $y=21-5x$ ③$\div 2$
If $x=0$, $y=21$
If $y=0$, $x=4\ 1/5$
If $x=1$, $y=16$
If $x=5$, $y=4$
We are now ready to plot the graph.

②

x	y
0	21
4½	0
1	16
5	−4



②

X	Y
0	21
4½	0
1	16
5	-4

The range for x is 0 to 5 1/3. Let one space on the x scale represent 1/3.

The range for y is −4 to 21.

Let each space on the y scale represent one. Locate the dots as before $x=0$, $y=4$. If x is 0 we do not go to the right at all. If y is 4 we go *up* 4. $x=5\ 1/3$, $y=0$. If x is 5 1/3 we go to the right 5 1/3. If y is 0 we do not go up at all. If x is 2 2/3 we go 2 2/3 to the right. If y is 2 we go up 2. This gives us a straight line graph for ①.

Plot ② in the same way. Notice the last pair. If x is 5 we go to the right 5. If y is −4 we of course go 4 *downward*.

Again the graphs intersect. What two numbers locate the intersection? $x=4$, $y=1$.

Try these two numbers in our problem.

Check *Ans.*

① 6 men at $4 =	$24	Men $4 per day
8 boys at $1 =	8	Boys $1 per day
	$32	
② 10 men at $4 =	40	
2 boys at $1 =	2	
	$42	

This is a somewhat cumbersome way to solve problems perhaps but there are two things to be said in its favor. With a little practice and with proper devices it gives solutions very rapidly. In fact modifications of this device are used more and more for the purpose of saving time.

Then too graphs are coming into such common use that we all need to know how to read them and, if need be, to make them.

PROBLEM 46. Find two numbers such that 5 times the first is 1 less than 8 times the second, and 15 times the first equals the amount by which 47 exceeds the second.

Let x = the first number
Let y = the second number
① $5x-8y=-1$
② $15x+y=47$
③ $5x=8y-1$ ①$+8y$
④ $x=\frac{8y-1}{5}$ ③$\div 5$
⑤ $y=47-15x$ ②$-15x$
$x=\frac{8y-1}{5}$ $y=47-15x$

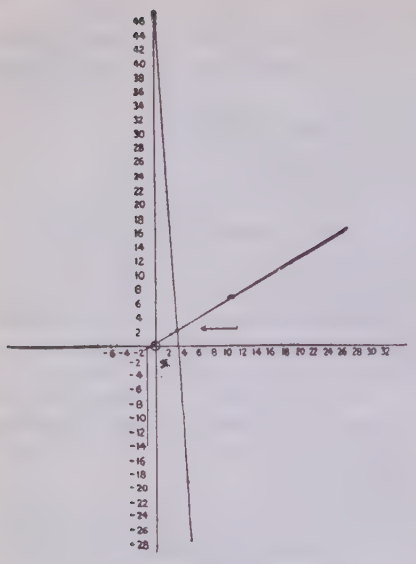
①

x	y
−1/5	0
2 2/5	1
3	2
11	7
19	12

②

x	y
0	47
3 2/5	0
5	−28

The range for x is −1/5 to +31
The range for y is −28 to +47



①

X	Y
-⅕	0
2⅖	1
3	2
11	7
19	12

②

X	Y
0	47
3⅖	0
5	28

Answer $x=3$, $y=2$
Checks
① $5(3)-8(2)=-1$
$15-16=-1$
$-1=-1$
② $15(3)+2=47$
$45+2=47$
$47=47$

Solve by the graphical method.

1. $x+2y=5$ $3x+7y=17$ *Ans.* 1, 2
2. $3x+7y=22$ $2x+y=11$ *Ans.* 5, 1

It is interesting to try to solve by the graphical method $x+y=8$ and $x+y=12$. Try it.

You will find that the graphs are parallel. They do not meet at all. Why not? Because it is impossible to find two numbers which will add to make 8 and at the same time add to make 12.

ADDITION AND SUBTRACTION

Before studying the *algebraic* method of solving these pairs of linear equations, it may be helpful to review what we have learned about combining terms.

Addition in algebra is more often arranged horizontally than vertically. Ordinarily we have such combinations as we have already made in solving equations.

Unite similar terms:

$3x+6-2x+5+x-3-12$

This is done mentally as follows:

$3x$ less $2x$ is x, plus x is $2x$
6 plus 5 is 11, less 3 is 8, less 12 is minus 4
Ans. $2x-4$

Unite

$6-7x+4-x-2+5x-3$
6 plus 4 is 10, less 2 is 8 less 3 is 5
Short $7x$ less x is short $8x$, plus $5x$ is short $3x$
Ans. $5-3x$

$12x+3-15x-3+8x-2$
$12x$ less $15x$ is short $3x$, plus $8x$ is $5x$
3 less 3 is 0, less 2 is short 2
Ans. $5x-2$

1. $10x-8+3x-2x+7-x$
2. $5x-4x-3x+6+8x-1$
3. $A+B-2A-3B+8A$

It will be found profitable to make several more exercises like these and practice them orally until they go quickly and easily. There are two illustrations which are very helpful. One is money or profit and loss, the other is the thermometer scale.

We wish to unite $8x$ and $-10x$. The illustration is: We *have* \$8, we *spend* \$10. This leaves us \$2 *in debt*. $8x-10x\equiv-2x$. Again $-12x+3x$. The thermometer stands at 12 *below*, it goes *up* 3. Where does it stand? At 9 *below*. $-12x+3x\equiv-9x$.

Use these illustrations while you are learning.

Add $3x-2y+8$
$4x-y-2$

We say mentally $3x$ and $4x$ is $7x$
Short $2y$ and short one more y is $-3y$
8 less 2 is 6

Our answer then is

$7x-3y+6$

Add $x-3y-5$
$2x+8y+5$

$3x+5y$

Add $-2x+8y-7$
$-2x-y+3$

$-4x+7y-4$

Add $A-B+C-8$
$-A-B-3C$

$-2B-2C-8$

Make more of these exercises for practice.

Perform the *subtraction* indicated

$3x-7y-(2x+8y)$

Noticing that the directions tell us to subtract *both* terms in the parenthesis, we write $3x-7y-2x-8y$. Uniting we have $x-15y$.

Again $17-4x-(2x+5)$

We can do this mentally: Say 17 *minus* 5 is 12. Why do we say *minus* 5? Because the 5 is in the parenthesis and we are told to *subtract* all the terms in the parenthesis.

Short $4x$ and *short* $2x$ gives a shortage of $6x$.

The answer is, $12-6x$.

$2A-6B-C-(A+B+C)$
$2A$ minus A is A
Short $6B$ minus B is short $7B$
Short C minus C is short $2C$
Ans. $A-7B-2C$

$2a+3b-(2a+2b+6c)$
$2a$ minus $2a$ is zero
$3b$ minus $2b$ is b

The $6C$ must also be subtracted but there is no C to subtract it from. If you have no money in your pocket and you order a pair of shoes at \$6, you *owe* \$6. From no C subtract $6C$ and we have minus C.

Ans. $b-6C$.

$7-(2a-3)$

Write this out because it is the hardest case in subtraction. $7-2a$——but what about the 3? The directions say from 7 take $(2a-3)$, that is take 3 less than $2a$. When we write $7-2a$ we have taken away too much. We were told to take away 3 less than $2a$, and we have taken away the whole of $2a$. Since we have taken away too much we must *put back* something. We took away 3 too much so we will *put back* 3.

Our answer is $7-2a+3$. Uniting the 7 and 3 we have $10-2a$.

A good illustration of what we have just done is this:

$15-(8-2)$

This says from 15 take $(8-2)$, that is take away 2 less than 8, or take away 6.

$15-6=9$

Writing it as we did in the preceding exercise: $15-8$——we have now taken away 2 too much. We must put back the 2.

$15-8+2=9$, the correct answer.

Another way to look at this case.

$7-(2a-3)$ We are told to take away a shortage of three, a debt of 3. Now taking away your debt is the same as *giving* you money. If your father pays \$3 that you owe at the store he helps you as much as if he gave you \$3 and let you pay the debt.

In other words taking away minus 3 is the same as adding 3. Hence we write $7-2a+3$.

$3x-2y+8-(x+3y-2)$

$3x$ less x is $2x$
Short $2y$ less $3y$ is short $5y$
8 *plus* 2 is 10. We say *plus* 2 because taking away a shortage is the same as *adding*.

Ans. $2x-5c+10$.

$7a-6b+2c-5-(7a-8b+3)$
$7a-6b+2c-5-7a+8b-3$
Ans. $2b+2c-8$

Compare the last three terms in the second line with the last three terms in the first line.

The $7a$ was plus $7a$: it is now minus $7a$.
The $8b$ was minus, now it is plus.
The 3 was plus and is now minus.

Subtracting then had the effect of making each plus sign into a minus and each minus into a plus.

A rule is often stated in algebra: to subtract change all the signs in the number to be subtracted and then add. By "change the signs" is meant to read each *plus* as a *minus*, and to read each minus as a plus.

This rule will do well enough if you remember that it applies only in subtraction and that merely means that to *take away* $2a$ we write $-2a$, while to take away $-3b$ we must add $3b$.

One of the most dangerous habits in algebra is to say glibly, "Change the signs" without thinking why. In reality there is no such process in algebra as changing the signs.

Subtract $3x-4y+5$
$2x+5y+3$

Say mentally $3x$ *minus* $2x$ is x
$-4y-5y-9y$
5 -3 is 2
Ans. $x-9y+2$

Subtract $2a+7b-8c-6$
$3a-5b+c-2$

$-a+12b-9c-4$

Mentally
$2a$ minus $3a$ is $-a$, $7b+5b$ is $12b$
$-8c-c$ is $-9c$, $-6+2$ is -4

The pupil who goes past this point in algebra without *understanding* how to subtract and without practicing enough to subtract well is almost sure to fail.

Before taking more exercises we want to learn how to check so that we may be sure that we are subtracting correctly.

Subtract 8
3
—
5

How can we be sure that 5 is the correct answer? By *adding* the 3 and 5 which gives us the 8 we started with.

Subtract $3x+7y-2$
$2x-3$

$x+7y+1$ *ans.*
$3x+7y-2$ *check*

Subtract $2a+3b-4c$
$3a-3b+3c+5$

$-a+6b-7c-5$ *ans.*
$2a+3b-7c$ *check.*

In doing the rest of these exercises do not depend too much on the rule. Better use your common sense in subtracting.

1. $2a-2b+3c-d-(5a-3b+4c-7d)$
2. $3x-7y+5xy-(2x-7y+3xy)$
3. $a-(2a-2b+3c-5)$

Subtract

4. $2-7x-5y$
   $3-6x+2y$
5. $2a+3b-c$
   $3a-b+5$

You can make more practice exercises for yourself.

SIMULTANEOUS EQUATIONS

The pairs of two-letter linear equations we solved in problems 44 and 45 are called by the long name, simultaneous, which means, "at the same time." This is because we solve them by finding one pair on numbers which will check both equations at the same time. Another and better name is, "linear pair."

We are now ready to solve them by algebraic means without using graphs.

1. $\begin{cases} ① \ x+2y=11 \\ ② \ x+\ y=\ 8 \end{cases}$

Why can we not solve this pair as we did our simple equations at the beginning of algebra? Because we have *two* letters. If we could get rid of one letter we could go ahead as before.

The question then is how to get rid of one letter. There is one step which will get rid of the x's in the two equations above.

Shall we add, subtract, multiply, or divide them?

Try it. The one which succeeds is subtraction.

③ $y=3$ ① − ②

This gives us one answer. Finding the other is an entirely different task. If we know that $x+y$ is 8 and that y is 3, how can we find x?

④ $x+3=8$ ③ substituted in ②

We substitute the 3 in place of y in ②

⑤ $x=5$ ④ -3

Check *Ans.*

① $5+2(3)=11$ $\begin{cases} x=5 \\ y=3 \end{cases}$

$5+6=11$

$11=11$

② $5+3=\ 8$

$8=\ 8$

2. $\begin{cases} ① \ 5x+y=21 \\ ② \ 3x+y=13 \end{cases}$

③ $2x=\ 8$ ① − ②

④ $x=\ 4$ ③ ÷ 2

⑤ $20+y=21$ ④ sub. in ①

⑥ $y=\ 1$ ⑤ − 20

Check *Ans.*

① $5(4)+1=21$ $\begin{cases} x=4 \\ y=1 \end{cases}$

$20+1=21$

$21=21$

② $3(4)+1=13$

$12+1=13$

$13=13$

3. $\begin{cases} ① \ 6x+y=22 \\ ② \ 5x+y=19 \end{cases}$

Ans.

$x=3$

$y=4$

4. $\begin{cases} ① \ x+\ 8y=16 \\ ② \ x+13y=16 \end{cases}$

5. ① $2x+7y=52$

② $2x-3y=\ 8$

③ $10y=60$ ① − ②

④ $y=\ 6$ ③ ÷ 10

⑤ $2x+42=52$ ④ in ①

⑥ $2x=10$ ⑤ − 42

$x=\ 5$ ⑥ ÷ 2

Check *Ans.*

① $10+42=52$ $x=5$

$52=52$ $y=6$

② $10-18=-8$

$-8=-8$

6. ① $8y+x=23$

② $6y-x=\ 5$

Here we have a little something new. Subtracting one of these equations from the other will not get rid of the x. What process will do so? Addition.

③ $14y=28$ ① + ②

④ $y=\ 2$ ③ ÷ 14

⑤ $16+x=23$ ④ in ①

$x=\ 7$ ⑤ − 16

Check *Ans.*

① $16+7=23$ $x-7$

$23=23$ $y=2$

② $12-7=\ 5$

$5=\ 5$

7. ① $6x+9y=66$

② $-6x-2y=-38$

③ $7y=28$ ① + ②

④ $y=\ 4$ ③ ÷ 7

⑤ $6x+36=66$ ④ in ①

⑥ $6x=30$ ⑤ − 36

⑦ $x=\ 5$ ⑥ ÷ 6

Check *Ans.*

$30+36=66$ $x=5$

$-30-8=-38$ $y=4$

8. $\begin{cases} 10x-2y=96 \\ 8x+2y=84 \end{cases}$

9. $\begin{cases} ① \ 5x+8y=34 \\ ② \ 9x+2y=24 \end{cases}$

In this pair of equations neither addition nor subtraction will eliminate, that is get rid of, either the x or the y. Why did the x's drop out in exercise 5 when we subtracted, while they will not do so in exercise 9? Because the two x's had the same coefficient. If we can alter our equations so that either the x's or the y's will have the same coefficient, we can subtract and go ahead. If we multiply ② by 4, what coefficient will y have?

③ $36x+8y=96$ ② × 4

④ $-31x\ \ =-62$ ① − ③

⑤ $62=31x$ ④ + 31x + 62

⑥ $2=x$ ⑤ ÷ 31

⑦ $10+8y=34$ ⑥ in ①

⑧ $8y=24$ ⑦ − 10

⑨ $y=\ 3$ ⑧ ÷ 8

Check *Ans.*

① $10\div24=24$ $x=2$

$34=34$ $y=3$

② $18+\ 6=24$

$24=24$

10. ① $6x+\ 4y=\ 90$

② $3x+15y=123$

First we shall make the coefficients of the x's alike.

③ $6x+30y=246$ ② × 2

④ $-26y=-156$ ① − ③

⑤ $156=\ 26y$ ④ + 26y + 156

⑥ $6=\ y$ ⑤ ÷ 26

⑦ $6x+24\ =\ 90$ ⑥ in ①

⑧ $6x=\ 66$ ⑦ − 24

⑨ $x=\ 11$ ⑧ ÷ 6

Check *Ans.*

① $66+24=\ 90$ $x=11$

$90=\ 90$ $y=\ 6$

② $33+90=123$

$123=123$

11. ① $2x+7y=49$

② $6x-5y=17$

① × 3

12. ① $4x+3y=22$

② $3x+5y=11$

In this pair we cannot make the coefficients of either x or y alike by multiplying either equation. How shall we accomplish it? By multiplying *both* equations.

③ $12x+\ 9y=66$ ① × 3

④ $12x+20y=44$ ② × 4

⑤ $-11y\ =22$ ③ − ④

⑥ $-22\ =11y$ ⑤ + 11y − 22

⑦ $-\ 2\ =\ y$ ⑥ ÷ 11

⑧ $4x+3(-2)=22$ ⑦ in ①

⑨ $4x-\ 6\ =22$ ⑧ same values

⑩ $4x=28$ ⑨ + 6

⑪ $x=\ 7$ ⑩ ÷ 4

Check *Ans.*

① $28-\ 6=22$ $x=\ 7$

$22=22$ $y=-2$

② $21-10=11$

$11=11$

We can just as well solve exercise 12 by eliminating the y's instead of the x's. Try it.

③ $20x+15y=110$ ① × 5

④ $9x+15y=\ 33$ ② × 3

⑤ $11x\ =\ 77$ ③ − ④

⑥ $x=\ 7$ ⑤ ÷ 11

⑦ $28+\ 3y=\ 22$ ⑥ in ①

⑧ $3y=-6$ ⑦ − 28

⑨ $y=-2$ ⑧ ÷ 3

The check consists in comparing this pair of answers with the pair obtained by the first method. *Ans.* $x=\ 7$, $y=-2$

13. ① $2x/3+3y/4=\ 700$

② $y+100=\ 5x/6$

③ $8x+9y=\ 8400$ ① × 12

④ $6y+600=\ 5x$ ② × 6

⑤ $-5x+6y=-\ 600$ ④ − 5x − 600

⑥ $16x+18y=\ 16800$ ③ × 2

⑦ $-15x+18y=-1800$ ⑤ × 3

⑧ $31x\ =\ 18600$ ⑥ − 7

⑨ $x=\ 600$ ⑧ ÷ 31

⑩ $4800+9y=\ 8400$ ⑨ in ③

⑪ $9y=\ 3600$ ⑩ − 4800

⑫ $y=\ 400$ ⑪ ÷ 9

Check *Ans.*

① $\frac{1200}{3}+\frac{1200}{4}=700$ $x=600$

$y=400$

$400+300\ =\ 700$

$700\ =\ 700$

② $\frac{\ }{\ }+\frac{\ }{\ }=3000$

$400+100\ =\frac{\ }{\ }$

$500=500\quad 6$

14. ① $\frac{x+3}{y+3}=\frac{5}{6}$

② $\frac{x-3}{y-3}=\frac{2}{3}$

③ $6(x+3)=5(y+3)$ ① × 6(y+3)

④ $6x+18=5y+15$ ③ same values

⑤ $6x-5y=-3$ ④ − 5y − 18

⑥ $3(x-3)=\ 2(y-3)$ ② × 3(y−3)

⑦ $3x-9\ =2y-6$ ⑥ same values

⑧ $3x-2y=\ 3$ ⑦ − 2y + 9

⑨ $6x-4y=6$ ⑧ × 2

⑩ $-y=-9$ ⑤ − ⑨

⑪ $9=y$ ⑩ + y + 9

⑫ $3x-18=\ 3$ ⑪ in ③

⑬ $3x=21$ ⑫ + 18

⑭ $x=\ 7$ ⑬ ÷ 3

Check *Ans.*

① $10/12=5/6$ $x=7$

$5/6=5/6$ $y=9$

② $4/6=2/3$

$2/3=2/3$

Turn back to problems 44, 45, 46 and see if you can solve their equations by the method of elimination and get the same results we got by the graphical method.

It was suggested that we try to solve by the graphical method the pair.

① $x+y=\ 8$

② $x+y=12$

If you tried it you found that the two graphs were parallel. They had no intersection. The equations were inconsistent, that is they could not both be true at the same time.

Try the new method on them.

① $x+y=\ 8$

② $x+y=12$

③ $0=-4$ ① − ②

Equation ③ is an absurdity.

When we subtract both x and y drop out. Again we have no answer.

Sometimes we have more than two unknown letters in a set of equations.

①	$3x+4y+5z=39$	
②	$x+2y+3z=19$	
③	$4x+5y+7z=51$	
④	$3x+6y+9z=57$	②×3
⑤	$-2y-4z=-18$	①−④
⑥	$4x+8y+12z=76$	②×4
⑦	$-3y-5z=25$	③−⑥

What have we accomplished so far? We have reduced our set from three equations with three unknowns to two equations with two unknowns. Now proceed as usual.

⑧	$-y-2z=-9$	⑤÷2
⑨	$-3y-6z=-27$	⑧×3
⑩	$z=2$	⑦−⑨
⑪	$-y-4=-9$	⑩ in ⑧
⑫	$5=y$	$11+y+9$
⑬	$3x+20+10=39$	⑩ and ⑫ in ①
⑭	$3x=9$	$13-30$
⑮	$x=3$	$14\div3$

Check	*Ans.*
① $9+20+10=39$	$x=3$
$39=39$	$y=5$
② $3+10+6=19$	$z=2$
$19=19$	
③ $12+25+14=51$	
$51=51$	

APPROXIMATE COMPUTATION AND MEASUREMENT

The first thing to decide in making any measurement is the unit in which to express the result. A distance may be measured in miles or feet or inches or meters or in any one of many other units. We ordinarily let our convenience decide what unit we shall use.

When the last measurement mark comes exactly at the end of the distance we are measuring, the length number is a whole number; when it does not come exactly at the end of the distance, the measurement is continued in subdivisions of the unit. We divide a foot up into 12 inches and divide the inch in halves, fourths, eights and so on. This system of subdivision is cumbersome and has been replaced where accurate work is done by a division of the foot into tenths. Why? You will see for yourself if you undertake to find the area of a rectangular field using first the ordinary subdivision and then the decimal subdivision.

Find the area of a rectangular field whose length is 32 feet 8 1/4 inches and width is 11 ft. 6 1/8 inches. The same problem stated decimally gives the length 32.7 ft. and width 11.5 ft. Which can you compute the more quickly? Wherever we can we shall use decimal subdivisions, to save time.

No human measurement is absolutely correct. This surprising statement may require considerable thought to convince you of its truth, but let us see. A carpenter in fitting boards measures them and saws them to perhaps the nearest eighth of an inch; for fine cabinet work he measures and saws to the nearest thirty-second of an inch. Only experienced and careful carpenters can do such fine work. A machinest making tools may work to the nearest thousandth of an inch; but no trained workman, no matter how expert, ever claims that his work is precisely correct. He tells instead how close it is. After making the finest measurements that have ever been made, using the most elaborate instruments and painstaking care, the expert discusses the *amount of his error.*

If you will measure the width of a block of wood yourself you will be convinced that a skilled workman with a better ruler could measure more accurately than you have. His measurement could be improved in turn by the use of a magnifying glass, and so on. No human measurement is absolutely correct.

The precision of measurement is shown by the *number of figures* required to express the result and not, as is often assumed, by the number of places *after* the decimal point. Suppose a length of a line is measured to the nearest hundredth of a foot, as 7.35 feet; the result may just as well be recorded as 88.2 inches, or 2.24 meters or even as .00139 miles. Each of these numbers expresses the same degree of accuracy though one of them has one place after the point and another has five places.

Quoting from the Evans & Marsh "First Year Mathematics": "Measurements which are expressed like these, in three figures, are said to be of three-figure accuracy: they may be made with ordinary instruments and skill. Five-figure accuracy requires good instruments and great care, as where a city building lot is measured to thousandths of a foot: six-figure accuracy is possible to experts: and eight-figure accuracy is beyond human skill at present."

Ordinary measurements are made as close as we need them for the use to which they are to be put. Some measurements are made as accurately as we can make them. Cases of the second kind are the standards of length which are kept by the United States government, or better still the international standard which is kept in Paris. It is measured just as accurately as men know how to measure.

Let us examine the last figure of a measured number. The length of a building lot is recorded as 43.7 feet. Is the 7 exactly 7 or may it be a little more than 7 or a little less? Suppose the field was remeasured with more care, the length might be found to be 43.72 feet. Again it might be measured with great care and this time the result might be 43.718. Now if the last measurement is correct to five figures, was the 7 of our first measurement exactly 7? No, it was really a little more than 7. It was the closest we could record it to three figures.

Change one third to a decimal. The answer is .3. But this is not exactly correct. Try again .33. Again our answer is not exact, .333 is closer, and .3333 is closer still. In fact we cannot write a decimal which is exactly equal to 1/3. The last figure is never exact. It is the best we can do to three figures or four figures or five figures, etc.

One more illustration: the number 3.1416 which is the ratio of the circumference of a circle to its diameter is not exactly 3.1416, more accurately stated it is 3.14159—and so on. For ordinary use 3.14 is sufficiently accurate, but the 4 is not exactly 4 as you know.

The last figure of all such numbers is peculiar; it is never an exact number: it is the best we can do in that place.

This has very important results in computing with such numbers. Let us find the area of a rectangular strip whose length is 43.72 ft. and width 3.831 feet. The last figure of each number is approximate. Whenever we multiply by the 2 or the 1 our product will be only approximate. Underline all the approximate figures.

```
  43.72
   3.831
  ------
   4372      The 9 is an approximation
  13116      only and all the figures after
 34976       the 9 are entirely worthless.
 13116       There are two things to be
-------      understood here.
167.49132
```

First that we do not *care* what the area of the strip is to the nearest $\frac{1}{100000}$ of a square foot, as our answer pretends to show. It is not necessary to measure land to such a degree of accuracy.

Second we *cannot* get our answer correct to more than four figures because we measured to only four figures.

The area of our field will then be set down as 167.5 square feet. This is as close as we can get it from our measurements and it is as close as we need it for any practical purposes.

Men who figure with measured numbers have resorted to various devices to shorten the labor of computation. A table of logarithms is one such device and a slide rule is another. Both these and other similar devices make use of the principle we have just learned: thay *cut off the number at the required number of places.*

The question for us is, Is there a method of multiplication which will save setting down these unnecessary figures? There is and it takes but a few minutes to learn it. Once learned it saves a great deal of time.

It will seem a little strange at first but after a little practice you will never multiply in the old way again.

The first thing to notice is that we can get the same result by multiplying "backwards" as forwards. It makes no difference whether we begin to multiply these numbers with the 7 or with the 2. The product is the same either way.

```
  134      134
  247      247
 ----     ----
  938      268
  536      536
268        938
-----    -----
32098    32098
```

One way is no harder or easier than the other, except that one way is strange and one is familiar.

We will now find the area of our rectangular strip again multiplying in the reverse or natural order.

```
 43.72
  3.831
 -----
 13116      The result is the same
 34976      as before.
  13116
   4372
 -------
167.49132 Square feet.
```

Now we will cut off the doubtful figures as we multiply.

```
  ' ' '
 43.72      We want only four figures
  3.831     in our result. When we
            multiply 43.72 by 3 we get
            five figures. Therefore we
```

check off the 2 before beginning to multiply. Then we say 3 times 2 is 6 but do not put down the 6; instead say carry one. 3 times 7 is 21 and 1 is 22. Set down 2 and carry 2.

1312 — Continue as usual.

Check off the 7. 8 times 7 is 56 do not put it down, but carry 6 because 56 is nearer to 6 tens than to 5 tens.

350 — Check off the 3. 3 times 3 is 9, carry 1.

13 — Check off the 4. 1 times 4 is 4, nothing to carry, because we do not carry to the next column unless we have 5 or more.

Add:

167.5 Square feet.

We still have to locate the point in our answer. We do this by common sense. The number we had to multiply was about 40. The number we had to multiply it by was about 4. Therefore our answer is about 40 times 4 or 130. Therefore our point goes after the 7. We *know* that our answer is 167.5 not 16.75 or 1.675 or 1675.

This is very important in handling numbers to know about how large our answer ought to be before we begin. This prevents absurd results.

We will check by setting the 3.831 above the 43.72 and multiplying again.

```
  ' ' ' '
3.831
43.72
------
1532
 115
  27
   1
------
167.5
Check
```

Estimate: 40×4 is 160. Check off the 1 and go ahead as before.

The "5 case"

The number we have last checked off never gives us anything to *set down* but it may give us something to *carry*.

```
15.25
2.123
------
3050
 153
  30
   5
------
32.38
```

Estimate: 15 times 2 is 30. We do not check off the 5 the first time because 15.25 times 2 gives us only 4 figures. Now check off the 5. 1 times 5 is 5, shall we carry 1 or nothing? 5 is just midway between 0 and 10. The simplest rule is to carry when we have 5 or more. Now say 1 times 2 is 2 and 1 is 3. Check off the 5. 3 times 5 is 15, carry 2. Point off after the 2 because we *know* our answer is about 30.

```
Check
2.123
15.25
------
2123
1062
  42
  11
------
32.38
```

Estimate: 2×15=30.

Make more exercises for yourself.

```
 345
21.6
------
 690
  35
  20
------
7450
```

350×20 is 7000

We must add a cipher in order to get about 7000.

```
Check
21.6
 345
------
 648
  86
  11
------
7450
```

20×300=6000.

Division

```
   2.19
  ------
  ' '
35.2)87.2
   704
  ------
    68
    35
    --
    33
    32
```

Estimate $\frac{80}{35}=2$

Now check off the 2 in the divisor because it would give us too many figures.

The point will come after the 2, because the answer must be about 2.

```
Check
  ' '
2.19
35.2
------
 657
 110
   4
------
87.1
```

35×2=70

It is clear that our answer, 2.19, is a little too small. When we check our product is 87.1. This is .1 too small. It is possible that 2.20 might be more accurate. Let us try it.

```
Second Check
  ' '
2.20
35.2
------
 660
 110
   4
------
87.4
```

This time we get 87.4 which is .2 more than the correct value. Therefore 2.20 is *not* a more accurate answer; 2.19 is the best possible answer to three-figure accuracy.

It is important to think correctly here. A great deal of the figuring done by practical men, in technical schools, and in the great fields of engineering, is done to three-figure accuracy only, because that is sufficient for their purpose.

Such men would call the answer to our division, 2.19, choosing always the *nearest* figure in the *last* place.

Divide 7267 by .1146.

```
  ' ' '
.1146
------
63410 Answer
------
7267
6876
------
 391
 344
------
  47
  46
  --
   1
```

It is a little more convenient to place the divisor over the dividend, leaving space for the answer.

Our estimate, or rough check, is 1/10 into 7000 = 70,000.

When we get the four figures of our answer, 6341 we have still to place the point.

We know that 1/10 will go into 7000 about 70,000 times. We must add a zero to make our answer 63,430.

```
Check
  ' ' '
63410
.1146
------
6341
 634
 254
  38
------
7267
```

1/10 of 60,000 = 6000

Divide 5.234 by 8.967.

```
  ' ' ' '

------
5.234
4484
------
 750
 717
------
  33
  27
  --
   6
```

Estimate 5/9 = .6

Point goes before the 5 because answer must be about .6.

```
Check
  ' ' ' '
.5838
8.967
------
4670
 525
  35
   4
------
5.234
```

5/10 of 9 = 5.

Square Root

What is the square root of 16? It is 4. If we divide 16 by 4 what is the answer? It is 4. Whenever we divide a number by its own square root we get the same square root for an answer. Stated another way that is merely saying that 4×4=16.

A square root may be defined as *one of the two equal factors* of a number.

There are several methods of finding the square root of a number. The guess and try method will teach you most about square root and most about dealing with numbers. The use of a table is the quickest. We will consider the guess and try method. You can learn the use of a table yourself.

Find the square root of 16. Suppose we do not know what it is. We *estimate* that it is 3. Divide 3 into 16. If 3 is the correct square root how will we know? The answer will be 3. But 3 into 16 goes about 5 times. Therefore 3 is not *one of the two equal factors* of 16, 3 is too small, 5 is too large. If we "split the difference" we get 4 which is the correct square root of 16.

These steps will find the square root of any number. Reread the last paragraph and find the square root of 41.12.

First we will make as good a guess as possible.

6×6=36 Therefore 6 is too small.
7×7=49 Therefore 7 is too big.
6.5×6.5=42.25 Therefore 6.5 is too big.

We will try 6.4.

First trial.

```
  ' ' ' '
6.400
------
6.426 Ans. 1.
------
41.12
3840
------
 272
 256
------
  16
  12
  --
   4
```

Our guess was 6.400. Our answer is 6.426. Our two factors are not equal. Split the difference. The difference is .026. Half of it is .013. Add this to the 6.400 or subtract it from the 6.426. In either case we get 6.413.

Second trial.

```
  ' ' '
6.413
------
6.413 Ans. 2.
------
41.12
3848
------
 264
 256
------
   8
   6
   -
   2
```

This time our two factors are equal.

The square root of 41.12 is 6.413.

Find the square root of 86.32.

8× 8= 64
9× 9= 81
10×10=100

86 is between 81 and 100, therefore the square root is between 9 and 10 but much nearer 9 than 10. Try 9.2.

First trial		Second trial
′ ′ ′ ′		
9.200	Difference .182	9.291
9.382		9.290
86.32		86.32
8280	1/2 of .182=.091	8363
352	9.200	269
276	.091	186
76	9.291	83
74		83
2		0

The only question remaining is whether 9.291 or 9.290 is nearer.

First check	Second check
9.291	9.290
9.291	9.290
8362	8361
186	186
83	83
1	
	85.30
86.32	

The first product is nearer the correct value, therefore 9.291 is the square root to four place accuracy.

Find to four places, the square root of 2.

1 ×1 =1
2 ×2 =4
1.5×1.5=2.25

The square root lies between 1 and 1.5 but nearer 1.5. Try 1.4.

First trial.		Second trial.
1.400		1.414
1.428	Difference .028	1.414 *Ans.*
2.000		2.000
1400		1414
600	1/2 of .028=.014	586
560		566
40		20
28		14
12		6
11		6

This is sometimes written $\sqrt{2}=1.414$.

In this way you can make a table for yourself. Next find the square root of 3, and so on.

Equations With Approximate Coefficients.

① $3.42x-4.25+8.13x=18.11$
② $11.55x=22.36$ ①+ 4.25
③ $x=1.94$ ②÷11.55

Check

$3.42\times1.94-4.25+8.13\times1.94=18.11$
$6.64-4.25+15.77=18.11$
$18.2=18.1$

Ans.
1.94

Notice that we expect this equation to check to 3 figures only.

COMPUTATION

′ ′ ′ ′

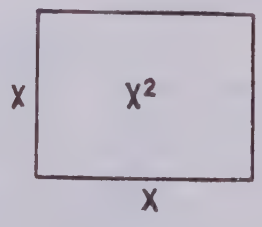
342 308 14 → 6.64
813 732 32 → 15.77

1. $2.73x-42.1+7.63x=54.6$
2. $82.7+36.1x=18.2x-3.00$

MULTIPLICATION

We have considered the simple and most common cases of multiplication:

$4(x-3)$ which equals $4x-12$.



and $x-4(x-2)$ which equals $x-(4x-2)$ which equals $x-4x+8$. Now consider the case:

$(x+3)(x+5)$. This clearly means that both terms in the first parenthesis are to be multiplied by both terms of the second parenthesis.

That is $x(x+5)+3(x+5)$
$xx+5x+3x+15$
Uniting similar terms
$xx+8x+15$

The form xx becomes cumbersome if we have much multiplying to do. For convenience it is written x^2, and read x square.

The reason for this name is that it is the area of the square which is x on each side.

In the same way xxx is x^3, read $x-$ cube; $xxxx$ is x^4, read $x-$ fourth; $xxxxx$ is x^5, read $x-$ fifth, and so forth.

Multiply $(x-5)(x-6)$
$x(x-6)-5(x-6)$
$x^2-6x-(5x-30)$
$x^2-6x-5x+30$
$x^2-11x+30$

The same two multiplications may be more conveniently arranged thus: The four lines indicate the four steps of the multiplication. The x^2 and the 10 are called the straight products. The $3x$ and $5x$ are cross products.

$x+3x$
$+5x+15$
x^2+3x
$+5x+10$
$x^2+8x+10$

$x-5$
$x-6$
x^2-5x
$-6x+30$
$x^2-11x+30$

Just why it is +30 is not clear in this case but looking back to the other method we see that we had to subtract −30, which is the same as *adding* 30.

Whenever you have two numbers both with minus signs, to multiply, the product is plus because one of them in effect puts the other in a minus parenthesis.

x^2-5x-3
$-x+4$
$-x^3+5x^2+3x$
$4x^2-20x-12$
$-x^3+9x^2-17x-12$

$x-y$
$x+y$
x^2-xy
$+xy-y^2$

This is a very common case in multiplication and becomes so familiar that we remember it. Other illustrations of the same case are:

x^2-y^2
$(a+b)(a-b)\equiv a^2-b^2$
$(x+5)(x-5)=x^2-25$
$(ax+4)(ax-4)=a^2x^2-16$
$[(x-3)-5][(x-3)+5]\equiv(x-3)^2-25$
$[(x+2)-7][(x+2)+7]\equiv(x+2)^2-49$

There are other cases to remember.

$(x+3)(x+3)\equiv(x+3)^2\equiv x^2+6x+9$
$(x+8)^2\equiv x^2+16x+64$

$x+8$
$x+8$
x^2+8x
$+8x+64$
$x^2+16x+64$

Notice that 16 is *double* the 8, and that 64 is the *square* of 8.

$(x-3)^2\equiv x^2-6x+9$
$(x-8)^2\equiv x^2-16x+64$
$(x+y)^2\equiv x^2+2xy+y^2$
$(x-y)^2\equiv x^2-2xy+y^2$
$(x+10)^2\equiv x^2+20x+100$
$(x-10)^2\equiv x^2-20x+100$
$(x-10)(x+10)\equiv x^2-100$

x^2y+xy^2
$x-y$
$x^3y+x^2y^2$
$-x^2y^2-xy^3$
x^3y-xy^3

Division

If we multiply 2 by 6 we get 12. If we divide the 12 by the 6 we get back the 2. This gives us the key to division.

$x\times x=x^2$, therefore $\frac{x^2}{x}\equiv x$

This may also be written $\frac{xx}{x}\equiv x$

$2x)6x^2$ → $3x$

$5xy^2)10xy^3$ → $2y$

$7x^2y^3)21x^5y^3$ → $3x^3$

Now try a longer division.

First multiply $(x+6)(x+5)$

$x+6$
$x+5$
x^2+6x
$+5x+30$
$x^2+11x+30$

Divide $x^2+11x+30$ by $x+6$.

We know the answer must be $x+5$. We want a method for getting $x+5$. Arrange our work as in arithmetic.

$x+6$

x

$x^2+11x+30$

The first step is simple: x into x^2 goes x times. x then is the first term of the answer.

Looking back to the multiplication we see that the $11x$ is made of two parts, $6x$ and $5x$. We must get out the $5x$ in order to get the second term in our answer, namely 5.

$x+6$

$x+5$ *Ans.*

$x^2+11x+30$

x^2+6x

Multiply the $x+6$ by the x.

Subtract

$5x+30$

$5x+30$

This gives $5x+30$, the lower line of our product back again.

x into $5x$ goes 5 times.

There are than three steps in each long division divide, multiply, subtract; and these are repeated in the same order as many times as is needful.

Divide $x^2+5x-24$ by $x-3$.

$x-3$

$x+8$ *Ans.*

$x^2+5x-24$

x^2-3x

$8x-24$

$8x-24$

Divide $x^3+7x^2+14x+8$ by $x+2$.

$x+2$

x^2+5x+4 *Ans.*

$x^3+7x^2+14x+8$

x^3+2x^2

$5x^2+14x+8$

$5x^2+10x$

$4x+8$

$4x+8$

Divide $x^3+x^2y+xy^2+y^3$ by $x+y$.

$x+y$

x^2+y^2 *Ans.*

$x^3+x^2y+xy^2+y^3$

x^3+x^2y

xy^2+y^3

xy^2+y^3

Divide x^3-y^3 by $x-y$.

$x-y$

x^2+xy+y^2 *Ans.*

x^3-y^3

x^3-x^2y

x^2y-xy^2

x^2y-y^3

xy^2-y^3

xy^2-y^3

Notice that x^2y cannot be subtracted from $-y^3$ because they are not similar terms.

$x+y$

x^2-xy+y^2 *Ans.*

Check

x^2-xy+y^2

$x+y$

$x^3-x^2y+xy^2$

$+x^2y-xy^2+y^3$

x^3+y^3

x^3+x^2y

$-x^2y+y^3$

$-x^2y-xy^2$

x^3+y^3

xy^2+y^3

xy^2+y^3

Divide $a^5+15+10a-a^4-3a^3-4a^2$ by a^2+2a+3.

Notice that the terms are not arranged in systematic order.

Rearrange thus:

$a^5-a^4-3a^3-4a^2+10a+15$ putting the highest power first.

a^2+2a+3

a^3-3a^2+5 *Ans.*

$a^5-a^4-3a^3-4a^2+10a+15$

$a^5+2a^4+3a^3$

$-3a^4-6a^3-4a^2$

$-3a^4-6a^3-9a^2$

$5a^2+10a+15$

$5a^2+10a+15$

Check

a^3-3a^2+5

a^2+2a+3

$a^5-3a^4+5a^2$

$2a^4-6a^3+10a$

$3a^3-9a^2+15$

$a^5-a^4-3a^3-4a^2+10a+15$

FACTORING

The expression $5(x-2)$ tells us to multiply x and -2 both by 5. This gives $5x-10$. It is sometimes convenient to be able to reverse this process and take the five out again.

$5x-10\equiv 5(x-2)$. This simple process is called taking out a distributive factor. We take out the 5 which is distributed; that is which is in both the $5x$ and the -10, and put it out side the parenthesis.

Cover up the left hand row below and see if you can write them yourself.

$3x-9\equiv 3(x-3)$

$5x+50\equiv 5(x+10)$

$ax+a^2\equiv a(x+a)$

$3a^2b-3ab^2-6a^2b^2\equiv 3ab(a-b-2ab)$

$8x^2-72x+32\equiv 8(x^2-9x+4)$

Learn to recognize a distributive factor at a glance.

The three special cases of multiplication which were mentioned as worth remembering give us three more kinds of factoring.

First: $(x+y)^2=x^2+2xy+y^2$

$(x+9)^2=x^2+18x+81$

$(x+2a)^2=x^2+4ax=4a^2$

$(3x+5)^2=9x^2+30x+25$

Multiply out some of these yourself, both on paper and mentally.

A harder one:

$[(x+3)+a]^2$

We will do as we did before, square the first part $(x+3)^2$; then multiply the first by the second and double the answer $2a(x+3)$: then square the second a^2

$(x+3)^2+2a(x+3)+a^2$

Second: $(x-y)^2$

This is really just the same as the first only the sign of the y is minus instead of plus.

Multiply and discover for yourself how much of a change this makes in the product.

$(x-y)^2 \equiv x^2-2xy+y^2$

$(x-9)^2 \equiv x^2-18x+81$

$(3x-5)^2 \equiv 3x^2-30x+25$

$[(x+3)-a]^2\equiv(x+3)^2-2a(x+3)+a$

Third: $(x+y)(x-y)$

This is the odd case where the cross products disappear and only the end products remain.

$x+y$

$x-y$

x^2+xy

$-xy-y^2$

x^2-y^2

$(x+y)(x-y)\equiv x^2-y^2$

$(x+8)(x-8)\equiv x^2-64$

$(x+2a)(x-2a)\equiv x^2-4a^2$

$(3x+5)(3x-5)\equiv 9x^2-25$

$[(x+3)-a][(x+3)+a]\equiv(x+3)^2-a^2$

$[(x+5)-2][(x+5)+2]\equiv(x+5)^2-4$

Learn to go, in these columns, from left to right (multiplication) and from right to left (factoring).

Factor

$x^2+2xy+y^2$ *Ans.* $(x+y)^2$

$x^2-2xy+y^2$ *Ans.* $(x-y)^2$

$x^2-8x+16$ *Ans.* $(x-4)^2$

$x^2-10x+25$ *Ans.* $(x-5)^2$

x^2-25 *Ans.* $(x-5)(x+5)$

x^2-64a^2 *Ans.* $(x-8a)(x+8a)$

$25x^2-100y^2$ *Ans.* $(5x+10y)(5x-10y)$

$(x+2)^2-36$

Ans. $(x+2-6)(x+2+6)\equiv(x-4)(x+8)$

$(3x-4)^2-49$

Ans.

$(3x-4-7)(3x-4+7)\equiv(3x-11)(3x+3)$

x^4-y^4

Ans.

$(x^2-y^2)(x^2+y^2)\equiv(x-y)(x+y)(x^2+y^2)$

$a^2-20ab+100$ *Ans.* $(a-10b)^2$

Notice that in the first and second kinds the coefficient of the second term is a *double* and the last term is the *square* of the same number.

$x^2-10x+25\equiv(x-5)^2$

The 10 is double 5, the 25 is the square of 5.

If we multiply $x+3$ by $x+2$:

$x+3$

$x+2$

x^2+5x+6

The coefficient of the second term is the sum of the 3 and 2. The last term is the product of 3 and 2.

Factor

x^2+5x+6 *Ans.* $(x+3)(x+2)$

We factored this expression by finding two numbers whose sum is 5 and whose product is 6. It is another guess and try method. Practice it.

$x^2+8x+12$ *Ans.* $(x+6)(x+2)$

$x^2+10x+9$ *Ans.* $(x+9)(x+1)$

$x^2+18x+32$ *Ans.* $(x+16)(x+2)$

$x^2+22x+57$ *Ans.* $(x+3)(x+19)$

$x^2-11x+18$ *Ans.* $(x-9)(x-2)$

Here the signs of the 9 and 2 must be minus so that their sum will be -11.

$x^2-15x+50$ *Ans.* $(x-10)(x-5)$

$x^2-8a+12$ *Ans.* $(a-6)(a-2)$

$a^2-8ab+15b$ *Ans.* $(a-8b)(a-3b)$

$x^2+10x-24$ *Ans.* $(x+12)(x-2)$

The sum of $+12$ and -2 is $+10$: the product of $+12$ and -2 is -24.

$x^2+18x-63$ *Ans.* $(x+21)(x-3)$

$x^2+20x-125$ *Ans.* $(x+25)(x-5)$

$a^2+6ab-55b$ *Ans.* $(a+11b)(a+5b)$

$x^2-10x-24$ *Ans.* $(x-12)(x+2)$

The sum of -12 and $+2$ is -10; their product is -24.

$x^2-18x-63$ $(x-21)(x+3)$

$a^2-3a-460$ $(a-23)(a+20)$

$x^2-14xy-51y^2$ $(x-17y)(x+3y)$

The next kind is a little harder. At least it often takes more trials.

Multiply

$4x+15$

$2x+9$

$8x^2+30x$

$36x+135$

$8x^2+66x+135$

Factor $8x^2+66x+135$

To get $8x^2$ we may multiply x by $8x$
or $2x$ by $4x$
To get 135 we may multiply 1 by 135
or 3 by 45
or 9 by 15

We want the combination which will give cross products whose sum is $66x$
Try some:

x	1	
$8x$	135	
	$135x$	
	$8x$	
	$143x$	This is not the combination.
x	3	
$8x$	45	
	$24x$	
	$45x$	
	$69x$	Not the one
x	9	
$8x$	15	
	$72x$	
	$15x$	
	$87x$	No.
x	15	
$8x$	9	
	$120x$	
	$9x$	
	$129x$	No.
$2x$	15	
$4x$	9	
	$18x$	
	$60x$	
	$78x$	Not the one.
$2x$	9	
$4x$	15	
	$36x$	
	$30x$	
	$66x$	This is the combination we are seeking. Our factors are $2x+9$ and $4x+15$.

Factor $6x^2+46x+80$

$3x$	1		$3x$	40	
$2x$	80		$2x$	2	
	$240x$			$80x$	
	$2x$			$6x$	
	$242x$	No		$86x$	No
$3x$	8				
$2x$	10				
	$16x$				
	$30x$				
	$46x$	This is the one.			

Ans. $(3x+8)(2x+10)$

$3x$	80		$3x$	4	
$2x$	1		$2x$	20	
	$160x$			$8x$	
	$3x$			$60x$	
	$163x$	No		$68x$	No
$3x$	2		$3x$	20	
$2x$	40		$2x$	4	
	$120x$			$20x$	
	$4x$			$12x$	
	$124x$	No		$32x$	No

Factor $15x^2+28x+12$

$5x$	2		$5x$	6	
$3x$	6		$3x$	2	
	$6x$			$18x$	
	$30x$			$10x$	
	$36x$	No		$28x$	Yes

Ans. $(5x+6)(3x+2)$

Check

$5x + 2$
$3x + 2$

$15x^2+18x$
$10x+12$

$15x^2+28x+12$

Factor $20x^2-23x+6$

$4x$	2		$4x$	3	
$5x$	3		$5x$	2	
	$10x$			$8x$	
	$12x$			$15x$	
	$22x$	No		$23x$	Yes

Ans. $(4x-3)(5x-2)$

Multiply: $6x - 5$
$2x + 3$

$12x^2-10x$
$+18x-15$

$12x^2+ 8x-15$

Notice that the sign of the 15 is minus, and that the $8x$ is the *difference* between the $18x$ and the $10x$.

Now factor $12x^2+8x-15$

Try	$3x$	1		$6x$	3
	$4x$	15		$2x$	5
		$45x$			$30x$
		$4x$			$6x$
		$41x$	No		$24x$ No
	$3x$	15		$6x$	5
	$4x$	1		$2x$	3
		$60x$			$10x$
		$3x$			$18x$
		$57x$	No		$8x$ Yes: but it still remains to decide which is minus, the 5 or the 3.

Try making it -3. This gives us $-8x$. This is wrong.

Then it must be -5.

Ans. $(6x-5)(2x+3)$

Factor $24x^2-53x-7$

Ans. $(8x+1)(3x-7)$

Factor $6a^2-11a-10$

Ans. $(2a-5)(3a+2)$

Factor $12a^2-7ab-45b^2$

Ans. $(4a-9b)(3a+5b)$

It is not difficult to remember two more cases.

Factor x^3+y^3

Ans. $(x+y)(x^2-xy+y^2)$

Factor x^3-y^3

Ans. $(x-y)(x^2+xy+y^2)$

QUADRATIC EQUATIONS

PROBLEM 47. A farmer sets out apple trees so that the number of trees in a row is two more than the number of rows. If there are 624 trees, how many rows and how many trees in a row?

Let x=no. of rows.

Then $x+2$=no. of trees in a row.

$x(x+2)$=no. of trees in all (that is 624).

①	$x(x+2)=624$	
②	$x^2+2x=624$	① same values
③	$x^2+2x-624=0$	② -624
④	$(x+26)(x-24)=0$	③ factored

We have here two numbers multiplied together giving as a product zero. This is only possible if one or the other of the numbers equals zero.

⑤	$x-26=0$	
⑥	$x-24=0$	
⑦	$x=26$	⑤ $+26$
⑧	$x=24$	⑥ $+24$

Check

24 rows of 26 = 624 trees

Ans.

24 Rows. 26 trees in a row. The 26 rows would be the answer if the problem read, "two less trees in a row than rows."

Try problem 47 with these numbers.

1. 5 more trees in a row than rows, trees in all, 500.
2. 6 more trees in a row than rows, trees in all, 216.
3. 8 more trees in a row than rows, trees in all, 128.

PROBLEM 48. A rectangle is 15 feet long, and its area is 36 sq. ft. more than a square of the same width. How wide is it?

Let x=no. of ft. in width of rectangle (and square).

$15x$=no. of sq. ft. in area of rectangle.

x^2=no. of sq. ft. in area of square.

Area of square plus 36 sq. ft. = area of rectangle.

That is

①	$x^2+36=15x$	
②	$x^2-15+36=0$	① $-15x$
③	$(x-12)(x-3)=0$	② factored
④	$x-12=0$	
⑤	$x-3=0$	
⑥	$x=12$	④ $+12$
⑦	$x=3$	⑤ $+3$

Check

12′ by 12′ = 144
12′ by 15′ = 180
144 + 36 = 180

Ans.

Rectangle is 12 ft. wide

OR

3′ by 3′ = 9
3′ by 15′ = 45
9 + 36 = 45

Rectangle is 3 ft. wide

Here we have *two* answers to one problem and both answers are correct.

PROBLEM 49. A rectanglar room takes 68 feet of picture molding and 32 square yards of carpet. What is the size of the room?

Let x=no. of feet in width (short side).

$2x$=no. of feet in two short sides.

$68-2x$=no. of feet in two long sides, because there are 68 feet in all four sides.

$1/2(68-2x)$=no. of ft. in length. That is $34-x$.

$x(34-x)$=no. of sq. ft. in area. That is 288.

[Change 32 square yards to ft.]

①	$x(34-x)=288$	
②	$34x-x^2=288$	① same values
③	$0=x^2-34x+288$	② $+x^2-34x$
④	$0=(x-18)(x-16)$	③ factored
⑤	$x=18.$ 16	

Check

18
18
16
16

Ans.

18′ by 16′

68 ft. of molding
$18\times16=288$ sq. ft. $=32$ sq. yds.

PROBLEM 50. A fraction having 70 for its numerator is inverted and multiplied by 6. Its new value is one more than its original value. What is the fraction?

Let x=the denominator.

Then $\frac{70}{x}$=the fraction.

And $\frac{6x}{70}$=the fraction inverted and multiplied by 6.

The new value = one more than its original value.

$$\textcircled{1}\quad \frac{6x}{70}=\frac{70}{x}+1$$

$$\textcircled{2}\quad 6x^2=4900+70x \qquad \textcircled{1}\times 70x$$
$$\textcircled{3}\quad 6x^2-70x-4900=0 \qquad \textcircled{2}-70x-4900$$
$$\textcircled{4}\quad 3x^2-35x-2450=0 \qquad \textcircled{3}\div 2$$
$$\textcircled{5}\quad (x-35)(3x+70)=0 \qquad \textcircled{4}\ \text{factored}$$
$$\textcircled{6}\quad x=35$$
$$\textcircled{7}\quad 3x=-70$$
$$-70$$
$$\textcircled{8}\quad x=\frac{-70}{3}$$

Check

$$\frac{35}{70}\times 6=3$$
$$\frac{70}{35}=2$$
$$2+1=3$$

Ans. $\frac{-70}{3}$

The $\frac{-70}{3}$ will also check, though it makes a curious fraction.

Such equations as ④ above are often laborious to factor by the guess and try method. We need a more systematic process. "Completing the square" is such a process for factoring quadratics. Remember that if we square $x+6$ we get $x^2+12x+36$. The 12 is *double* the six and 36 is the *square* of 6. If we had the 12 but not the 36 how could we find the 36? By taking half of the double term and squaring it.

Factor $x^2+20x+96$.

The 20 is the double, therefore the original number is 10.

Its square is 100

$x^2+20x+100$ is the complete square.

$x^2+20x+100\ +96-100$ If we add 100 in order to get a perfect square, we must subtract 100 to bring the expression back to its former size.

Rewrite: $(x+10)^2-4$

or $(x+10)^2-(2)^2$

This is a familiar kind of expression to factor. It is called the difference of two squares.

$$(x+10-2)(x+10+2)$$

or $(x+8)(x+12)$ *Ans.*

Check

$$\begin{array}{r} x+8 \\ x+12 \\ \hline x^2+8x \\ +12x+96 \\ \hline x^2+20x+96 \end{array}$$

Solve

$$\textcircled{1}\quad x^2-6x-27=0$$
$$\textcircled{2}\quad x^2-6x+9-27-9=0$$
$$\textcircled{3}\quad (x-3)^2-36=0$$
$$\textcircled{4}\quad (x-3-6)(x-3+6)=0$$
$$\textcircled{5}\quad (x-9)(x+3)=0$$
$$\textcircled{6}\quad x=9,-3$$

Check

$$81-54-27=0$$
$$0=0$$
$$9+18-27=0$$
$$0=0$$

Ans. 9 or −3

Solve

$$\textcircled{1}\quad x^2+7x-18=0$$
$$\textcircled{2}\quad x^2+7x+\frac{49}{4}-18-\frac{49}{4}=0 \qquad \textcircled{2}+\frac{49}{4}-\frac{49}{4}$$

If 7 is the double, the original is $-\frac{7}{2}$. Its square is $\frac{49}{4}$.

$$\textcircled{3}\quad \left(x-\frac{7}{2}\right)^2-\frac{72}{4}-\frac{49}{4}=0$$
$$\textcircled{4}\quad \left(x-\frac{7}{2}\right)^2-\frac{121}{4}=0$$
$$\textcircled{5}\quad \left(x+\frac{7}{2}-\frac{11}{2}\right)\left(x+\frac{7}{2}+\frac{11}{2}\right)=0$$

Check

$$4+14-18=0$$
$$0=0$$
$$81-63-18=0$$
$$0=0$$

Ans. 2, −9

This is a hard way to solve an easy quadratic, and an easy way to solve a hard quadratic.

Solve

$$\textcircled{1}\quad 3x^2-x-2=0$$
$$\textcircled{2}\quad x^2-1/3x-2/3=0$$
$$\textcircled{3}\quad x^2-1/3x+1/36-2/3-1/36=0$$
$$\textcircled{4}\quad (x-1/6)^2-\frac{25}{36}=0$$
$$\textcircled{5}\quad (x-1/6-5/6)(x-1/6+5/6)=0$$
$$\textcircled{6}\quad (x-1)(x+4/6)=0$$
$$\textcircled{7}\quad x=1,\ -2/3$$

Check

$$3-1-2=0$$
$$0=0$$
$$3(4/9)+2/3-2=0$$
$$4/3+2/3-2=0$$
$$0=0$$

Ans. 1, −2/3

Solve

$$\textcircled{1}\quad x^2-8x+5=0$$
$$\textcircled{2}\quad x^2-8x+16+5-16=0$$
$$\textcircled{3}\quad (x-4)^2-11=0$$
$$\textcircled{4}\quad (x-4-\sqrt{11})(x-4+\sqrt{11})=0$$
$$\textcircled{5}\quad (x-4-3.32)(x-4+3.32)=0$$
$$(x-7.32)(x-.68)=0$$
$$\textcircled{7}\quad x=7.32 \text{ or } .68$$

Check

$$53.5-58.6+5=0$$
$$-5.1+5=0$$

Ans. 7.32 or .68

Notice the slight discrepancy in the check, which we always expect in approximate computation.

$$\begin{array}{rr} 7.32 & 7.32 \\ 7.32 & 8 \\ \hline 512 & 58.6 \\ 22 & \\ 1 & \\ \hline 53.5 & \end{array}$$

Try the second check for yourself.

We are now able to solve the three kinds of equations of elementary algebra. They are sufficient for the use of most of the equations and formulas you will find in your reading. The study of geometry and trigonometry will bring many more formulas within your reach.

PLANE GEOMETRY

INTRODUCTION

"The enemies of geometry, those who know it only imperfectly, look upon the theoretical problems, which constitute the most difficult part of the subject, as mental games which consume time and energy that might better be employed in other ways. Such a belief is false, and it would block the progress of science if it were credible. But aside from the fact that the speculative problems, which at first sight seem barren, can often be applied to useful purposes, they always stand as among the best means to develop and to express all the forces of human intelligence." —Abbé Bossut.

"It may seem strange that geometry is unable to define the terms which it uses most frequently, since it defines neither movement, nor number, nor space—the three things with which it is chiefly concerned. But we shall not be surprised if we stop to consider that this admirable science concerns only the most simple things, and the very quality that renders these things worthy of study renders them incapable of being defined. Thus the very lack of definition is rather an evidence of perfection than a defect since it comes not from the obscurity of the terms, but from the fact that they are so well known." —Pascal.

"We may look upon geometry as practical logic, for the truths which it studies, being the most simple and most clearly understood of all truths, are on this account the most susceptible of ready application in reasoning."—D'Alembert.

"The method of making no mistakes is sought by every one. The logicians profess to show the way, but the geometers alone ever reach it, and aside from their science there is no genuine demonstration."—Pascal.

HISTORICAL

Mathematics in general and geometry in particular have a very ancient and honorable history. Of all the sciences its development has been accompanied by the least error. One generation of mathematicians has not been chiefly occupied with the correction of the mistakes of the previous generation but has been free to devote its energies to further developments of the science.

The virtues of mathematics, precision in definition and logical exactness in reasoning, are especially evident in geometry. Its elements—the point, the line, and the plane—are the most universal of all concepts, and have always meant the same thing to all peoples, and this gives a common and undisputed ground for development. On the contrary, what may seem beautiful to one people at one time may not seem to be so at a later date. Even the moral values of acts are differently appraised by different ages and by different races, but the geometrical concepts have in them the elements of the unchangeable and eternal. The shortest distance between two points always has and always will bring to the mind the same concept—the line.

Our knowledge of what the ancients knew of geometry is limited to what may be inferred from inscriptions and tablets. Necessity often serves as the mother of invention, and hence the earliest geometry deals with the practical problems, such as the measurement of lands. The Babylonians had formulas for areas of squares, rectangles, and right triangles. They asserted that the circumference of a circle was three times its diameter. This is also the statement in the Bible in I Kings 7:23. The Egyptians, whose civilization goes back beyond record, had a practical use for geometry in the surveying of land, especially in the vicinity of the Nile, which so often floods its banks. In Herodotus we find: "They said also that this king divided the land among all Egyptians so as to give each one a quadrangle of equal size and to draw from each his revenues, by imposing a tax to be levied yearly. But every one from whose part the river tore away anything, had to go to him and notify what had happened; he then sent overseers, who had to measure out how much the land had become smaller, in order that the owner might pay on what was left, in proportion to the entire tax imposed. In this way, it appears to me, geometry originated, which passed thence to Hellas." The pyramids also are an enduring monument to the geometrical science of the Egyptians.

From the seventh century B. C. the Greeks came into active contact commercially and intellectually with the Egyptians. Plato, who visited Egypt said: "Whatever we Greeks receive, we improve and perfect." By 320 B. C. a Greek, Euclid, had written a geometry which in its translation has been used as the standard text almost universally in England until this century and is used at the present time in some places. The vogue of this text for over 2,200 years was deserved and has made the word Euclid synonymous with geometry. The Egyptians cared only for geometry as required in every day life but the Greeks were interested in the logical and speculative side of the science.

Soon there arose the three famous problems of geometry:

(1) To trisect an angle.

(2) To "double the cube", i. e., to find a cube whose volume is double that of a given cube.

(3) To "square the circle", i. e., to find a square exactly equal in area to a given circle.

These problems became the incentive of much geometrical study, and while they were never satisfactorily dealt with in ancient times those engaged in seeking the solutions were always finding out new and important geometrical truths. Many of the Greek philosophers, as Plato and Aristotle, were keenly interested in geometry. Plato wrote over the entrance to his school, "Let no one who is unacquainted with geometry enter here."

Euclid, whose name is by far the greatest in geometry, was born about 365 B. C. and wrote his Elements 330-320 B. C. He was extraordinarily skillful in arranging in an orderly and logical manner the facts and theorems of geometry. Very few of the separate proofs were his own, but his power to organize and systematize all the available knowledge of geometry entitles him to the high place he holds.

There are two stories handed down from the days of Euclid which indicate that human nature does not change and that the conflict between knowledge for its own sake and knowledge for utilitarian purposes only is not modern. When Ptolemy asked if there was no easy method of acquiring geometric knowledge Euclid replied: "There is no royal road to geometry." Literally hundreds of geometric texts have been written whose object is to make Euclid easy, but there are many who maintain that this product of Greek culture has never been surpassed.

A youth who had begun to read geometry with Euclid, when he had learned the first proposition inquired: "What do I get by learning these things?" So Euclid called his slave and said: "Give him three pence, since he must make gain out of what he learns." While the average man uses geometry very little yet he enjoys the advantages of modern inventions, all of which are the products of applied geometry.

Practical Utility.—How is geometry used? I walk a certain distance; here is the problem of the measurement of distance. I buy a piece of ground, a drawing must be made to indicate its shape and position for the deed; here is a problem of area. A tank must be constructed to hold so many gallons; here is a question of volume. A tunnel is to be made under a river, a bridge is to be constructed, a ship is to be built; all these are but a few of the many thousands of geometric problems. In war there are endless problems of geometry to solve. The position of a big gun, of an airplane, or of a submarine, is found by geometrical means.

Relation to Sciences.—Without a knowledge of geometry, progress in the study of physics is impossible. Indeed in the modern developments of physics, there has arisen a demand for peculiar concepts of space called non-Euclidean geometries and for what is known as four dimensional geometry. At present all matter is supposed to be composed of electric charges, positive and negative. The physical and chemical properties of all substances thus depend upon the manner in which these electrical charges are arranged. In the case of crystals many geometrical solids are found in nature.

Universality.—Geometry is founded upon statements about which there is universal agreement. History is supposed to deal with facts, but what passes for history in one country will not be accepted in another, and even in the same country opinions differ. Moreover, if the facts

themselves are not disputed, at least their interpretation is called in question. What is music to the Oriental ear is mere noise to the European. Often that which is considered beautiful in one age is derided in the next. But objects like the monuments of Greek architecture, which found their inspiration and proportions in the laws of geometry, have found universal admiration and approval, since the fundamental laws of geometry have been the same for all times and all peoples.

Essentials.—Geometry teaches the student to separate the essential from the non-essential. The statements of geometry when they have reached a final form are such that a single word can not be added or taken away without destroying the meaning.

Intellectual Beauty.—There is a unity, simplicity, and beauty in the development of geometry which appeals to many. Lincoln, whose writings and speeches are especially noteworthy for the above qualities, found joy in middle life in reading the proofs of Euclid.

Intellectual Requirements.—Geometry is especially fitted as a subject of study for the youthful mind. It demands intelligence, imagination, and diligence. Travel and experience add much to the ability to master many subjects but "there is no royal road to geometry."

1. Elements.—The elements first met with in plane geometry are the point and the line. We also require one plane in which all the points and lines are supposed to lie. Before we attempt to define these terms we must consider the nature of a definition.

2. Definition.—A definition is a statement explaining the precise meaning of a word or phrase. It should be complete and clear and in terms more simple and better known than the word defined.

3. Geometrical Definitions.—A few moments of thought will show the impossibility of definitions for the elements of geometry. We naturally choose for our fundamental elements the simplest; and if there were anything simpler than the point we should choose it as our first element rather than the point itself. Here is one of the advantages of geometry as a study: we all know what is meant by a point and a line and thus have a common body of knowledge upon which to build. There have been many clever descriptions of a point and of a line but one must acknowledge that if one did not know what was meant by the word point before reading the description one would not know afterward.

4. Point.—A point is that which has no part. A point is that which has position but no magnitude.

5. Line.—A line is that which has length without breadth or thickness. A line is breadthless length. Euclid's definition of a straight line is: A straight line is that which lies evenly with respect to the points on itself.

6. Axiom.—Certain facts are so elemental they can not be reduced to anything simpler. They are statements which meet with universal agreement and are called axioms.

7. Postulate.—A postulate is a geometric statement whose truth is assumed. The distinction between a postulate and an axiom is merely that the postulate is a geometric truth while the axiom is of broader application. Many ignore or neglect this distinction, and we shall at times.

There is a certain amount of freedom in our choice of axioms and postulates. There is always a choice in the fundamental unit. If one chooses the dollar as the unit then the cent is the one hundredth part of a dollar; if the cent is the unit then the dollar is one hundred cents.

Just as there are many different orders in which the separate stones of a building may be set, so also there have been many different lists of assumptions in geometry. We shall use the list from the New York State Syllabus in Geometry, which has itself been based on a list used by Harvard University in its entrance examinations.

8. One straight line, and only one, can be drawn through two given points.

9. Two points determine a straight line.

10. Two straight lines can intersect in only one point.

11. A straight line may be produced to any required length.

12. A straight line is the shortest path between two points.

13. A circle may be described with any given point as a center, and any given line as a radius.

14. Any figure may be moved from place to place without altering its size or shape.

15. Through any point outside a given line, one line, and only one, can be drawn parallel to the given line.

16. All straight angles are equal.

17. All right angles are equal.

18. From a given point in a given line, one perpendicular, and only one, can be drawn to the line.

19. Equal angles have equal complements, equal supplements, and equal conjugates.

If a careful man should build a house he might make a complete list of all the kinds of materials which entered into its construction and of the various tools which were necessary. Thousands of careful students and teachers have been over the subject of geometry and the above postulates, or assumptions, are the ones which have been found to be the most necessary and convenient.

Again, in the building of a house one might try to determine what was the least number of tools that were necessary, but in actual practice it is better to have a sufficient number. As a matter of fact, some of the above list of assumptions result from the others so the list is not so small as it might be. In a course in higher mathematics it would be proper to consider the question of the least number of assumptions, but for the beginner in geometry the number of the assumptions is not so important as their convenience. Having the assumptions listed, it is possible, when one becomes more familiar with the subject, to investigate their relations.

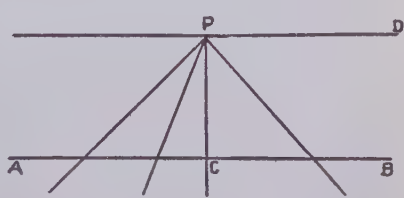
20. Equipment.—What equipment does a student need in the study of geometry? When we discuss this question we shall see the relation of the practical to the theoretical.

First, the student needs a sheet of paper, a slate, or a blackboard as a representation of a plane. On consideration it will be evident that no such thing as a perfect plane can be obtained. Your slate or blackboard is full of imperfections and your sheet of paper will refuse even to be flat unless it is placed on a good desk top. However, the idea of a perfect plane is fixed in our minds. We are content if a concrete sidewalk is fairly smooth, a plate glass window must be more accurately made, while the manufacturer of an astronomical instrument may work for months or years to obtain a smooth surface for an instrument requiring great accuracy. He must have a pencil, a piece of chalk, or an instrument of some kind to indicate points and draw lines. Any point we can make with a pencil has size but again as we make the point smaller, thus approaching the ideal, we increase the accuracy of our work. A ruler is necessary to aid in the drawing of straight lines and again this can only be approximately free from error. Finally a pair of compasses is necessary to draw circles. We shall leave to the reader the consideration of the question—why is a pair of compasses a more accurate instrument than a ruler?

From the earliest days the ruler and the compasses have been the only instruments that have been considered legitimate in the solution of plane geometry problems. To become proficient in many sciences requires elaborate equipment and costly apparatus but even crude drawings made in the sand enabled the ancient Greek scholars to attain their perfection in geometry.

21. Drawings.—We can now discuss the postulates §8-19 in reference to the making of geometrical drawings.

We represent points by small dots and put a capital letter as A in the vicinity of the point to label it.



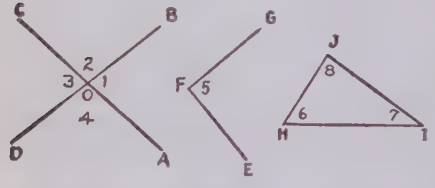
Two given points A and B determine the position of our ruler to draw the line with the symbol AB in agreement with §8-9 which line by §11 we can extend in either direction beyond the points A or B.

With our pencil we can draw any number of paths or curves between the points A and B but §12 tells us that the straight line drawn with our ruler is the shortest distance between the two points.

In the moving of a figure from one position to another according to §14 we have a theoretical and practical difference. Any physical object, if moved from one position to another on our earth, would in general experience many changes due to the alteration of the force of gravity, of the atmospheric pressure, of the temperature, etc., which would change its shape, but one readily imagines the ideal solid which experiences no change.

22. Uniqueness.—Geometry is particularly concerned with unique objects. The highest mountain, the largest city, the worst war have an immediate significance. The designation of any other mountain, city or war requires many words. When two points A and B are given the first unique object determined is the line AB which can be prolonged in either direction.

23. Segment.—When we consider the portion of the line AB which lies between A and B we have a second unique object called the line—segment AB, which has related to it a unique number called its length.



Consider the line AB and the point P outside it. Consider all the lines which can be drawn through P, two of these lines are unique in reference to AB, i. e., PC and PD.

24. Parallel.—(Symbol II). Two lines are called parallel when they lie in the same plane and do not intersect however far they are produced. There is one line and one only, §15, which passes through P and is parallel to AB, i. e. PD. This is a very famous axiom or postulate and in the past there have been many attempts by well known mathematicians to derive it from the other postulates.

The two rails of a railroad correspond to our ideas of parallel lines and if prolonged forever in straight lines we believe they would never meet, and it seems as if there should be some way to prove it.

The proof is impossible, for it has been shown that it is the realm of possibility for something entirely different to take place. Lobatschewski (1793-1856) showed that the postulate that more than one parallel can be drawn through a point to a given line leads to a consistent and at the same time a different geometry. In this geometry the sum of the angles of a triangle is less than two right angles. Riemann (1826-1866) took as his postulate that there is no parallel to a line from a point outside it. This leads to still another consistent geometry in which the sum of the angles of a triangle is greater than two right angles. This of course leaves it to experiment or observation to find out which is the true geometry. If the true geometry is that of Euclid then the sum of the angles of a triangle should be always two right angles. I see a man in New York and I again see him in Canton, China. He may have gone from one place to the other by way of the Atlantic or the Pacific oceans, but it is also a geometric possibility that he went through the center of the earth. How he did go can be accurately answered only from observation of his trip.

25. Ray or Half Line.—When two lines intersect in a point the plane is divided into four parts. AC and BD intersect in O dividing the plane into the four parts 1, 2, 3, 4.

We designate a line beginning at a definite point and extending indefinitely in only one direction as a ray or half line. OA and OC are half lines.

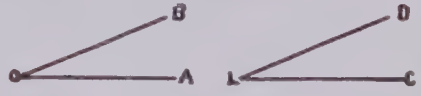
26. Angle.—(Symbol ∠). When two half-lines or rays extend indefinitely from a common point the figure formed is an angle. The concept of the half-line or ray is introduced to secure uniqueness. When two lines as AC and BD intersect in O we have four angles determined which we can designate by the numbers 1, 2, 3, 4. The common point is called the *vertex* and the two rays the *sides*. Thus angle 1 has the vertex O and the sides OA and OB and can be named the angle AOB or the angle BOA; the vertex letter is always written between the other two letters. When there is no danger of ambiguity we can designate the angle by a single letter or number, thus ∠JHI = ∠6 = ∠H; but it would not do to say the angle O, for there is not a unique angle at O.

27. Straight Angle.—Closely connected with the angle is the idea of a rotation. If OB turns about O as a fixed point counterclockwise while OA remains fixed the angle AOB will increase and OB will ultimately coincide with OC. The angle AOC or COA is called a straight angle. A straight angle is formed when the sides extend in opposite direction from a common vertex and form a straight line.

28. Geometric Figure.—Any combination of the geometric elements, points, lines, surfaces, and solids is a geometric figure.

29. Boundaries.—The boundaries of a geometric figure are the points, lines, or surfaces by which it is limited.

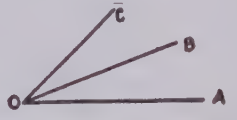
30. Polygon.—A polygon is a plane figure bounded by three or more straight lines.



Triangle.—(Symbol △). A triangle is a portion of the plane bounded by three straight lines, and is the simplest of the polygons.

31. Equality.—(Symbol =). Equality has various meanings in geometry. The fundamental equality is congruence.

32. Congruence—(Symbol ≅). Two geometrical figures are congruent if they can be made to coincide in all their parts by use of postulate §14.



The segment AB is congruent or equal to segment CD if AB can be made to coincide with CD. A can be made to coincide with C, the line AB to coincide with the line CD, then if B falls on D the segments coincide throughout and are congruent. Also if AB ≅ CD then AB ≅ DC.

The two angles AOB and CLD are congruent if it is possible to place them so that OA coincides with LC at the same time that OB coincides with LD, or in general that the vertices and sides can be made to coincide at the same time. Also they can then be made to coincide in the reverse order, that is OA with LD and OB with LC. These two methods are denoted symbolically by ∠AOB ≅ ∠CLD or ∠AOB ≅ ∠DLC.

A circle and a square, however, may have equal areas, but they are not capable of being made to coincide.

The method of showing that two figures are congruent by placing one upon the other so they coincide in all their parts is called proof by the method of *superposition.*

33. Adjacent Angles.—Two angles which have the same vertex and the side between them common are adjacent. Thus ∠AOB and ∠BOC are adjacent and ∠AOC is their sum.

34. Right Angles.—When two straight lines meet so that any two of the adjacent angles are equal the angles are called right angles. An angle less than a right angle is called an acute angle. An angle greater than a right angle is an obtuse angle.

35. Perpendicular.—(Symbol ⊥). Two lines are perpendicular when they meet to form right angles. There is but one line perpendicular to a given line at a given point by postulate §18. This is the second unique line PC of §23.

36. Complementary Angle.—One angle is the complement of another when their sum is a right angle. ∠AOB and ∠BOC are complementary angles.

37. Supplementary Angles.—One angle is the supplement of another if their sum is a straight angle or two right angles. ∠AOB and ∠BOC are supplementary.

38. Conjugate Angles.—One angle is the conjugate of another if their sum is two straight angles or four right angles, ∠1 and ∠2 are conjugate.

AXIOMS

39. If equals are added to equals, the sums are equal.

40. If equals are subtracted from equals, the remainders are equal.

41. If equals are multiplied by equals, the products are equal.

42. If equals are divided by equals, the quotients are equal.

43. Like powers or like positive roots of equals are equal.

44. If unequals are operated on by positive equals in the same way, the results are unequal in the same order.

45. If unequals are added to unequals in the same order, the sums are unequal in the same order; if unequals are subtracted from equals, the remainders are unequal in the reverse order.

46. Quantities that are equal to the same quantity or to equal quantities are equal to each other.

47. A quantity may be substituted for its equal in an equation or in an inequality.

48. If the first of three quantities is greater than the second, and the second is greater than the third, then the first is greater than the third.

49. The whole is greater than any of its parts and is equal to the sum of all its parts.

50. Magnitude.—Any thing that is measurable is a magnitude. The above axioms are universal statements which apply to numerical quantities or magnitudes. They enumerate all the operations that are necessary in dealing with numbers.

Consider axiom 45.

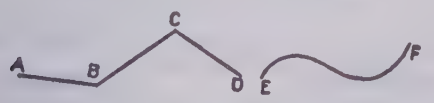
7 is greater than 3 or in symbols $7>3$,
6 is greater than 4 or in symbols $6>4$,
Adding 13 is greater than 7 Adding $13>7$.
10 equals 10 or in symbols $10=10$
6 is greater than 4 or in symbols $6>4$
Subtracting 4 is less than 6 Subtracting $4<6$

Of course nothing can be said about the result of adding unequals to unequals which are in the reverse order, as can be seen below.

$10>6$,
$3<13$,
Adding $13<19$,
but $10>6$
$3<4$,
Adding $13>10$.

Thus the first sum may be either greater or less than the second. The reader can verify the other axioms for numbers in a similar way.

51. Solids.—All the objects which we can see are solids. Physics is concerned with the nature and properties of the substances of which the physical solids are constituted, while geometry is concerned only with the shape and size of the solid. Thus a geometrical solid can not be seen or touched and has its existence only in the imagination.



52. Geometrical Solid.—A geometrical solid is a limited portion of space.

53. Surface.—The boundaries of a geometric solid are called surfaces. Consider some water standing in a glass. The exposed surface of the water is neither air nor water, it is what is between the air and the water.

A sheet of paper is a representation of a surface, or rather of two surfaces, as its two faces are separated by the thickness of the paper.

54. Line.—A line is the intersection of two surfaces. Thus in the case of water standing in a glass the surface of the water meets the surfaces of the glass in a curved line or an approximate circle, if the glass is an ordinary drinking glass.

We have already considered the straight line in § 5.

55. Broken Line.—A broken line is composed of portions of straight lines. AB+BC+CD is a broken line.

56. Curved Line or Curve.—Any line which is neither straight nor broken is a curved line. EF is a curved line.

57. Motion in Geometry.—Since geometry is closely connected with mechanics, which discusses the motion of physical objects, we should see the relation of motion to the fundamental elements of geometry.

A moving point generates a line.
A moving line generates a surface unless it moves along itself.
A moving surface generates a solid unless it moves along itself.

58. Plane.—A definition of a plane can be given in terms of points and lines. A plane is a surface such that a straight line joining any two of its points lies wholly within the surface.

59. Theorem.—Geometry is the study of the properties of figures and the relations which exist between them. The results of these studies are formulated in statements called theorems. A theorem consists of two parts: the hypothesis and the conclusion. The *hypothesis* gives all the conditions which are granted or assumed. The *conclusion* gives the result of these conditions. From the stand point of the student, a theorem is something which is to be proved; that is, he is to reproduce the steps by which the original discovery was made.

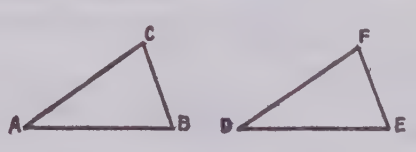
60. Proof.—A proof is an argument or an ordered arrangement of statements by which we show the truth of an assertion. For each statement given, a reason must be assigned.

These reasons must be—
(1) granted in the hypothesis,
(2) an axiom or postulate,
(3) a definition,
(4) or a theorem which has itself been previously proved. The student must take every opportunity to learn what the axioms postulates, and definitions mean; then he will be able to write them in his own words.

Read every word in a theorem, and if there is a single word or phrase of which you do not know the exact meaning, consult the definitions; because you can not be honest with yourself if you attempt to prove something when you do not understand what it is you are about to prove.

61. Method of Writing a Proof.—
(1) Write the theorem.
(2) Draw a figure indicating what is given.
(3) Write down the hypothesis.
(4) Write down the conclusion.
(5) Draw a line down the middle of the page and for each step written on the left of the line give the reasons on the right. This method will be followed for only a part of the propositions.

62. Symbols.—



$+$ plus.	$\triangle$ triangle.
$-$ minus.	$\triangle\triangle$ triangles.
$\times$ or multiplied by.	$\perp$ perpendicular, is perpendicular to.
$=$ equals.	$\perp s$ perpendiculars.
$\backsim$ equivalent, is equivalent to.	$\parallel$ parallel, is parallel to.
$\cong$ congruent, is congruent to.	$\parallel s$ parallels.
$\sim$ similar, is similar to.	$\square$ parallelogram.
$>$ is greater than.	$\square s$ parallelograms.
$<$ is less than.	$\bigcirc$ circle.
$\therefore$ therefore.	$\bigcirc s$ circles.
$\because$ since.	π ratio of the circumference to the diameter of a circle.
$\angle$ angle.	
$\measuredangle$ angles.	
$\sqrt{}$ square root, $\sqrt{16}=4$.	
$^\circ$ degrees.	
$'$ minutes.	
$''$ seconds.	

63. Abbreviations.—

Adj.	Adjacent.
Alt.	Alternate.
Ax.	Axiom.
Con.	Conclusion.
Cons.	Construction.
Corresp.	Corresponding.
Def.	Definition.
Ext.	Exterior.
Hyp.	Hypothesis.
Int.	Interior.
Post.	Postulate.
Rect.	Rectangle, Rectangular.
Rt.	Right.
Str.	Straight.
Sup.	Supplementary.

ANGLES, TRIANGLES AND PERPENDICULARS.

64. Theorem 1.—
If two triangles have two sides and the included angle of one equal respectively to two sides and the included angle of the other, the triangles are congruent.

Hyp. Given the triangles ABC and DEF, in which AB equals DE, AC equals DF, and the angle A equals the angle D.
Con. The triangle ABC is congruent to the triangle DEF.

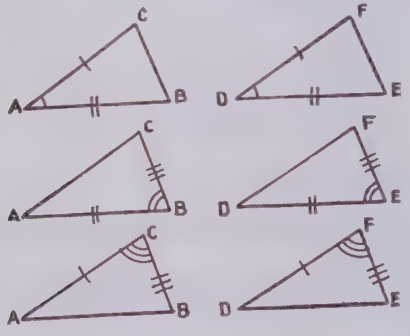
Proof.

Statements.	Reasons.
1. Place the triangle ABC on the triangle DEF so that the side AB coincides with its equal DE, and so that the point A falls on the point D and the point B on the point E.	1. §14. Postulate. Any figure may be moved from place to place without altering its size or shape. § 32. Definition. The segment AB is equal to the segment DE if AB can be made to coincide with DE.
2. The side AC will coincide with the equal side DF since the angle A equals the angle D.	2. §32. Definition. Two angles which are equal can be made to coincide. Angle A equals angle D by hypothesis.
3. Point C will fall on point F.	3. Segment AC equals segment DF by hypothesis.
4. Point B now coincides with point E, hence the side BC coincides with the side EF.	4. §8. Postulate. One straight line, and only one can be drawn through two given points.
5. Triangle ABC is congruent to the triangle DEF.	5. §32. Definition. Two geometrical figures are congruent if they can be made to coincide in all their parts.

Let us consider the proof of the theorem. It is obvious that when one looks at the drawing alone it is impossible to tell what is given or what is to be proved. There are six statements which can be made regarding the two triangles, (we will use the symbols of §62.)

$\angle A = \angle D$
$\angle B = \angle E$
$\angle C = \angle F$
$AB = DE$
$BC = EF$
$CA = FD$

But in geometry it is not enough to tell the truth. I may write down six truths



Water is wet.
The sky is blue.
The moon is a sphere.
There are seven days in the week.
Honesty is the best policy.
All crows are black.

It is impossible to trace any sequence in the above statements, or to show that one is the result of any number of the others, as is required in a geometric proof.

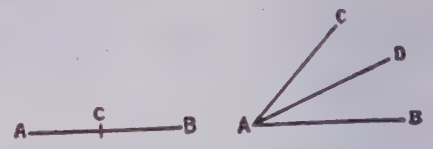
There are three ways in which the above figures can be used to prove the same theorem, starting with the three different hypotheses,

(1) $AB = DE$, $AC = DF$, $\angle A = \angle D$;
(2) $AB = DE$, $BC = EF$, $\angle B = \angle E$;
(3) $BC = EF$, $CA = FD$, $\angle C = \angle F$.

So it is especially important to know just which of these three cases has been chosen. This can often be indicated by markings on the equal segments and angles so that immediately on looking at the figure it will be possible to tell what facts are given in the hypothesis. The three figures below give in order the three possible hypotheses enumerated above.

From this point on we shall frequently make use of this method of indicating equal segments and angles.

65. Theorem 2.—
If two triangles have a side and the two adjoining angles of one equal respectively to a side and the two adjoining angles of the other, the triangles are congruent.



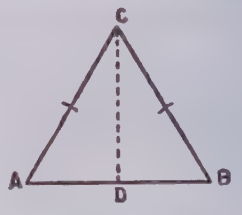
Hyp. In the triangles ABC and DEF, AB equals DE, angle A equals angle D, and angle B equals angle E.
Con. The triangles ABC and DEF are congruent.

Statements.	Reasons.
1. Place triangle ABC on triangle DEF so that segment AB coincides with its equal DE, with A falling on D and B on E.	1. §14. Postulate. Any figure may be moved from place to place without altering its size or shape. §32. Definition. The segment AB is equal to the segment DE if AB can be made to coincide with DE.
2. Then the line AC will coincide with the line DF and the line BC with the line EF, since angle A equals angle D and angle B equals angle E.	2. Angles are equal by hypothesis. They will coincide by definition, §32.
3. Point C will coincide with point F.	3. §10. Postulate. Two straight lines can intersect in only one point.
4. Triangle ABC coincides with triangle DEF. They coincide in all their parts.	4. Definition, §32.

66. Isosceles Triangle.—An isosceles triangle has two of its sides equal.

67. Bisect.—

To bisect a segment AB is to find the point C in the interior of the segment so that $AC = CB$. In which case C is called the mid-point of AB.

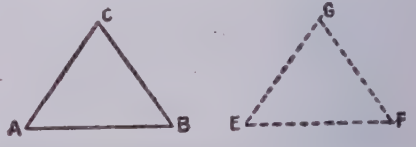


To bisect an angle BAC is to draw the half-line or ray AD so that $\angle BAD \cong \angle DAC$ in which case AB is called the bisector of the angle BAC.

How to actually find the point C and the line AD with the ruler and compasses will be shown later.

68. Corresponding, or Homologous Parts.—When two geometrical figures can be made to coincide, any two segments which coincide are called corresponding, or homologous, segments, and any two angles which coincide are called corresponding, or homologous, angles.

Corresponding, or homologous parts, of congruent figures are equal.

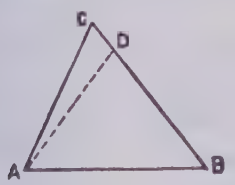


69. Theorem 3.—
In an isosceles triangle the angles opposite the equal sides are equal.

Hyp. In the triangle ABC, the side AC equals the side BC.
Con. The angle A equals the angle B.

Statements.	Reasons.
1. Draw CD the bisector of the angle C, meeting the side AB in D. Then the angle ACD equals the angle DCB.	1. §67. Definition of bisection.
2. Side AC equals side BC.	2. Hypothesis.
3. Side CD equals side CD.	3. Identical.
4. Triangle ACD is congruent to triangle BCD.	4. §64. Theorem. If two triangles have two sides and the included angle of one respectively equal to two sides and the included angle of the other, the triangles are congruent.
5. Angle A equals angle B.	5. Corresponding angles of congruent triangles, §68.

70. Theorem 4.—If two angles of a triangle are equal, the triangle is isosceles.



Hyp. Given $\triangle ABC$ with $\angle A = \angle B$.
Con. $AC = BC$ or $\triangle ABC$ is isosceles.

1. Suppose that EFG is ABC in a second position so that $ABC \cong EFG$.	1. Post. §14. Any figure can be moved from place to place without altering its size or shape.
2. Turn EFG over and place it on ABC so that F falls on A and E on B.	2. Post. §14. Same as above.
3. Since $\angle A = \angle B$, and $\angle B = \angle F$, $\angle A = \angle F$.	3. Ax. §46. Quantities that are equal to the same quantity or to equal quantities are equal to each other.

4. ∴ the line FG falls along the line AC.	4. Def. §32. Relative to congruent angles.
5. Similarly the line EG falls on the line BC.	
6. Hence G will coincide with C.	6. Post. §10. Two straight lines can intersect in only one point.
7. GF = AC.	7. §32. Definition.
8. But GF = CB.	8. Const.
9. ∴ AC = BC.	9. Ax. §46. Quantities that are equal to the same quantity or equal quantities are equal to each other.

71. Converse.—If the hypothesis and conclusion of a theorem are interchanged to form a new theorem, this theorem is called the converse of the original theorem. It will be observed that the theorem of §70 is the converse of the theorem of §69.

72. Theorem 5.—If one angle of a triangle is greater than a second angle, the side opposite the first angle is greater than the side opposite the second angle.

Hyp. Given △ABC with ∠A > ∠B.
Con. BC > AC.

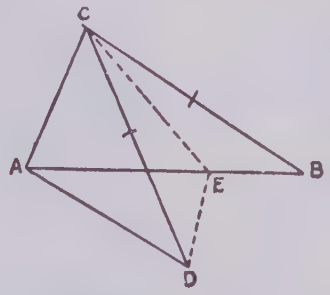
1. Draw the line AD meeting the side CB in D forming the ∠BAD = ∠CBA.	1. Construction.
2. AD will be in the interior of the ∠CAB.	2. Ax. §49. The whole is greater than any of its parts.
3. AD + DC > CA.	3. Post. §12. A straight line is the shortest path between two points.
4. In △ABD, ∠DAB = ∠DBA, AD = BD.	4. Construction. Theorem 4, §70. If two angles of a triangle are equal, the triangle is isosceles.
5. Substitute BD for its equal in 3, BD + DC > CA.	5. Ax. §47 A quantity may be substituted for its equal in an equation or in an inequality.
6. BD + DC = BC, ∴ BC > CA.	6. Ax. §49. The whole is equal to the sum of its parts. Ax. §47. A quantity may be substituted for its equal in an equation or in an inequality.

73. Proof by Exclusion.—Sometimes it is not possible or feasible to give a direct proof of a theorem, as has been done with the theorems so far considered. Another method is to make a complete enumeration of all the possible things which can happen and then to eliminate them one by one until there remains but a single possibility, and this must be the true condition of affairs.

The success of this method depends upon the completeness of the enumeration. Because a color is not green does not prove it is red. You do not necessarily find the letter which you were to mail and which you have concealed in a pocket, if you overlook a single pocket in going through your clothes.

In plane geometry a line is either perpendicular to another line or it is not perpendicular to it. Hence you have but two possibilities here; disprove one and you prove the other. In the case of two numbers x and y there are three possibilities, x greater than y, x less than y, or x equal to y; here you must show that two of these are impossible to be certain of the true result.

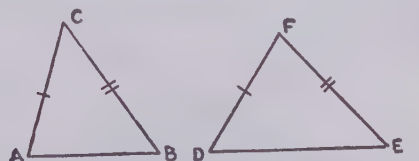
We shall now have opportunity to use this method.



74. Theorem 6.—If one side of a triangle is greater than a second side, the angle opposite the first side is greater than the angle opposite the second side.

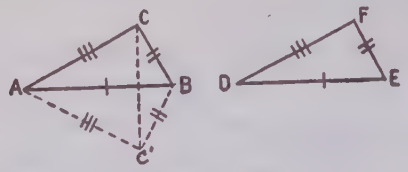
Hyp. Given △ABC with AC > BC.
Con. ∠B > ∠A.

1. There are only three possibilities regarding the ∠A and B, (I) ∠A = ∠B, (II) ∠A > ∠B, (III) ∠A < ∠B.	1. §73.
2. (1) If ∠A = ∠B then AC = BC, which is impossible.	2. Theorem 4. §70. If two angles of a triangle are equal the triangle is isosceles. Contradicts the hypothesis.
3. (II) If ∠A > ∠B then CB > AC, which is impossible.	3. Theorem 5. §72. If one angle of a triangle is greater than a second angle, the side opposite the first angle is greater than the side opposite the second angle. Contradicts the hypothesis.
4. ∴ ∠A < ∠B or ∠B > ∠A.	4. The only remaining possibility.



75. Theorem 7.—If two triangles have two sides of one respectively equal to two sides of the other, and the included angles unequal, the triangle which has the greater included angle has the greater third side.

Hyp. Given △ABC and ADC with AC = AC and CD = CB but with ∠ACB > ∠ACD.
Con. AB > AD.
Note. According to §14 we can imagine the two triangles moved until they have one pair of equal sides in common as AC.



1. Draw CE the bisector of the ∠DCB which meets AB in E.	1. §67.
2. CD = CB, CE = CE, ∠DCE = ∠ECB.	2. Hypothesis, Identical, Construction.
3. ∴ △DEC ≅ △BEC.	3. Theorem 1, §64. If two triangles have two sides and the included angle of one respectively equal to two sides and the included angle of the other, the triangles are congruent.
4. DE = EB.	4. Corresp. parts of congruent triangles §68.
5. AE + ED > AD.	5. Post. §12. A straight line is the shortest distance between two points.
6. AE + EB > AD.	6. Replacing ED by its equal EB.
7. AB > AD.	7. Ax. §49. The whole is equal to the sum of all its parts.

76. Theorem 8.—If two triangles have two sides of one respectively equal to two sides of the other, and the third sides unequal, the triangle which has the greater third side has the greater included angle.

Hyp. Given △ABC and DEF with AC = DF, BC = EF, but DE > AB.
Con. ∠DFE > ∠ACB., or ∠F > ∠C.
Hint. There are only three possibilities; (1) ∠C = ∠F, by §73. (2) ∠C > ∠F, (3) ∠C < ∠F.
Prove that the first two are impossible hence the third must be true.

77. Theorem 9.—If two triangles have the three sides of one respectively equal to the three sides of the other, the triangles are congruent.

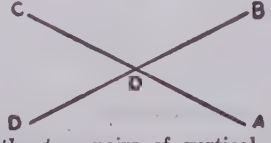
Hyp. Given the △ABC and DEF with AB = DE, BC = EF, and CA = FD.

Con. △ABC ≅ △DEF.

Let AB and DE be the longest sides of their respective triangles.

1. Suppose △DEF is brought into the position indicated by △ABC¹ so that DE coincides with its equal AB, D falling on A and E on B and F taking the position C¹.	1. Post. §14. Any figure may be moved from place to place without altering its size or shape.
2. Draw the line CC¹.	2 Post. §9. Two points determine a straight line.
3. AC = DF, DF = AC¹, ∴ AC = AC¹.	Ax. §47. A quantity may be substituted for its equal in an equation or in an inequality.
4. △C¹AC is isosceles and ∠ACC¹ = ∠AC¹C.	4. Theorem 3, §69. In an isosceles triangle the angles opposite the equal sides are equal.
5. In the same way ∠BCC¹ = ∠BC¹C.	
6. ∠ACC¹ + ∠BCC¹ = ∠AC¹C + ∠BC¹C.	6. Ax. §39. If equals are added to equals the sums are equal.
7. ∠ACB = ∠AC¹B.	7. Ax. §47. Same as above.
8. △ABC ≅ △AC¹B.	8. Theorem 1, §64. If two triangles have two sides and the included angle of one respectively equal to two sides and the included angle of the other, the triangles are congruent.
9. △AC¹B ≅ △DEF, ∴ △ABC ≅ △DEF.	9. Ax. §46. Quantities that are equal to the same quantity or to equal quantities are equal to each other.

78. Symmetrical Triangles.—Consider the three △, $A^1B^1C^1$, ABC, and $A^{11}B^{11}C^{11}$ with $AB = A^1B^1 = A^{11}B^{11}$, $BC = B^1C^1 = B^{11}C^{11}$, and $CA = C^1A^1 = C^{11}A^{11}$. If $\triangle A^1B^1C^1$ were cut out with a knife it

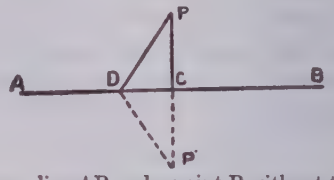


would be possible to slide it along to coincide with △ABC without removing it from its plane. In this case the two are called identical. But in order to make $\triangle A^{11}B^{11}C^{11}$ coincide with △ABC it is necessary to remove it from the plane and turn it over. Triangles ABC and $A^{11}B^{11}C^{11}$ are called symmetrical triangles.

Two triangles are identical when they have their sides arranged in the same order, symmetrical when they are arranged in the opposite order.

79. Vertical Angles.—Two angles are vertical when the sides of one are the prolongations of the sides of the other. See figure for theorem 10. Here are two pairs of vertical angles, ∡AOB, DOC and ∡AOD, BOC.

80. Theorem 10.—If two straight lines intersect each other, the vertical angles are equal.



Hyp. Given the two pairs of vertical angles ∠AOB and ∠COD, ∠BOC and ∠AOD formed by the straight lines AC and BD intersecting in O.

Con. ∠AOB = ∠COD and ∠BOC = ∠AOD.

1. ∠AOB + ∠BOC = a straight angle.	1. Def. §27.
2. ∠BOC + ∠COD = a straight angle.	2. Def. §27.
3. ∴ ∠AOB + ∠BOC = ∠BOC + ∠COD.	3. Ax. §46. Quantities that are equal to the same quantity or equal quantities are equal to each other.
4. ∠AOB = ∠COD, subtracting ∠BOC from each side of the above equality. In the same way prove that ∠BOC = ∠AOD.	4. Ax. §40. If equals are subtracted from equals, the remainders are equal.

81. Theorem 11.—There is not more than one perpendicular from a given point without a line to a line.

(Note. We will assume that there is one perpendicular, the method of constructing this perpendicular will be given later on §240.)

Hyp. Given a line AB and a point P without the line, with PC ⊥ AB and PD any other line through P meeting AB in D.

Con. PD is not ⊥ AB.

1. Prolong PC through C to P^1 making $CP^1 = PC$ and draw DP^1.	1. Post. §11. A straight line may be prolonged any required length.
2. In △DPC and DP^1C, ∠PCD = ∠P¹CD.	2. Def. §35. All right angles are equal.
3. PC = P¹C.	3. Cons.
4. DC = DC.	4. Identical.
5. △DPC ≅ DP'C.	5. Theorem 1, §64.
6. ∴ ∠PDC = ∠P'DC.	6. Def. §68. Corresponding parts of congruent figures.
7. Since PCD' is a straight line PDP' can not be a straight line.	7. Post. §8. One straight line, and only one, can be drawn through two given points.
8. ∴ ∠PDC + ∠P'DC is not a straight angle.	8. Def. §27.
9. ∴ 2(∠PDC) is not a straight angle.	9. Ax. §47. A quantity may be substituted for its equal in an equation or in an inequality.
10. ∴ ∠PDC is not one half of a straight angle or a right angle.	10. Ax. §42. If equals are divided by equals, the quotients are equal. Def. §27, 34. A right angle is one half of a straight angle.
11. PD is not ⊥ AB.	11. Def. §35.

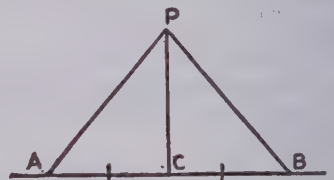
When we know how to draw the one perpendicular PC to the line AB we will be able to prove the theorem below.

From a given point without an unlimited straight line one perpendicular can be drawn to the line, and but one.

82. Theorem 12.—

The perpendicular is the shortest line that can be drawn from a point to a straight line.

We will merely indicate the steps in the proof leaving the reader to fill in the reasons. Making use of the figure of the previous theorem we must prove that PC is less than PD.



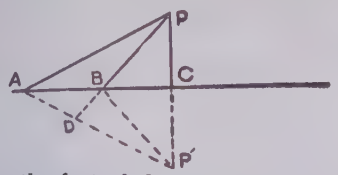
$PC = \frac{1}{2}(PP^1)$, $PD = \frac{1}{2}(PD + DP^1)$, but $PD + DP^1 > PP^1$.

∴ PD > PC.

83. Oblique Straight Line.—Any line which is not perpendicular to a given line is oblique to the line.

84. Theorem 13 —

If two oblique straight lines drawn from a point to a straight line meet the line at equal distances from the foot of the perpendicular drawn from the point to the line, they are equal.



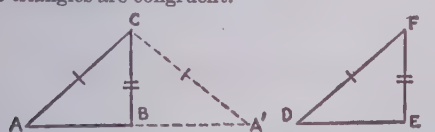
Hyp. PC is the ⊥ from P on AB, meeting it in C, the foot of the ⊥; PA and PB, two oblique straight lines, meeting AB in A and B respectively, so that AC = CB.

Con. AP = BP.

1. ∠ACP = ∠BCP.	1. Both are right angles.
2. PC = PC.	2. Identical.
3. AC = CB.	3. Hyp.

4. $\triangle ACP \cong \triangle BCP$. 4. Theorem 1, §64.
5. $AP = BP$. 5. Def. §68.

85. Theorem 14.—If two oblique straight lines drawn from a point to a straight line meet the line at unequal distances from the foot of the perpendicular, the more remote is the greater.



Hyp. C is the foot of the $\perp$ PC from P on AB. The two oblique lines PA and PB meet AB in A and B respectively so that $AC > BC$.

Con. $AP > PB$.

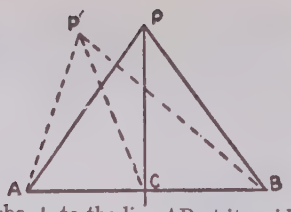
1. Prolong PC through C to P^1 so that $PC = CP^1$. Draw BP^1, AP^1. Let D be the intersection of AP^1 and PB, and if $AC > BC$ then D will be a point in the interior of the segment AP^1. 1. Post. §11.
2. $AD + AP > DP$. 2. Post. §12.
3. $AD + AP > DB + BP$. 3. Ax. §47.
4. $DB + DP^1 > BP^1$. 4. Post. §12.
5. Add the inequalities 3 and 4 $AD + AP + DB + DP^1 > DB + BP + BP^1$. 5. Ax. §45.
6. $DB = DB$. 6. Identical.
7. Subtract equation 6 from equation 5. $AD + AP + DP^1 > BP + BP^1$. 7. Ax. §44.
8. $AD + DP^1 = AP^1$. 8. Ax. §47.
9. $PA = AP^1$ and $PB = BP^1$. 9. Same proof as in Theorems 13, 84.
10. $2AP > 2BP$. 10. Ax. §47.
11. $AP > BP$. 11. Ax. §44.

86. Right Triangle.—A right triangle is a triangle which has one of its angles a right angle. The side opposite the right angle is called the hypotenuse. The other two sides are cal'ed the legs.

87. Theorem 15.—If two right triangles have the hypotenuse and a leg of one respectively equal to a hypotenuse and a leg of the other, the triangles are congruent.

Hyp. Given the two right triangles ABC and DEF with the right angles at B and E respectively. AC equals DF and CB equals FE.

Con. Triangle ABC is congruent to triangle DEF.



Hint. Place triangle DEF in the position CBA^1 so that FE coincides with its equal BC, E falling on B and F on C, while D takes the position A^1. Then ACA^1 is an isosceles triangle and $\angle A = \angle A^1$. (§69, Theorem 3. In an isosceles triangle the angles opposite the equal sides are equal.) Since $\angle A^1 = \angle D$, we have $\angle A = \angle D$. Now place triangle DEF on triangle ABC so that D falls on A and angle D coincides with its equal angle A. Since $AC = DF$, point F will coincide with C, while line DE falls along line AB. FE will fall along CB, since CB and FE are now perpendiculars from the same point to the same line. (§81. Theorem 11. From a given point without an unlimited straight line one perpendicular can be drawn to the line, and only one.) Hence CB coincides with FE and the triangle ACB and DEF are congruent.

88. Locus.—A locus consists of all points satisfying a given condition and of only those points satisfying the condition.

If you are given a box containing white and black balls and are told to sort out the white balls, you are to get all the white balls and none but the white balls.

In a locus problem you are to sort all the points in the plane and find those which satisfy the condition and those only. What makes the problem different from the sorting of the white and black balls is the fact that the number of points in the plane is very great, or infinite, so that in any particular problem some way must be likewise found to pick out a great number at once, such as finding a line, which consists of an infinite number of points, such that all the points of the line satisfy the condition.

89. Theorem 16.—The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.

Hyp. PC is the $\perp$ to the line AB at its mid-point C.

Con. PC is the locus of points equidistant from A and B.

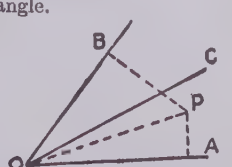
1. Let P be any point of the line PC and draw the lines AP and BP. 1. Pos. §9.
2. $AC = CB$, $\measuredangle ACP$ and BCP are rt. $\measuredangle$. 2. Hyp.
3. $\therefore \triangle APC \cong \triangle BCP$. 3. Theorem 15. §87.
4. $\therefore AP = BP$. 4. Corresponding parts of congruent triangles §68.

This proves that all points on CP are equidistant from A and B, but we must show that we have all points which are equidistant from A and B. Two methods are possible to complete the proof. First, we can show that all points which are equidistant from A and B are on PC. Second, we can show that any point which is not on PC can not be equidistant from A and B.

First Method.

5. Let P^1 be a point which is equidistant from A and B. Draw the straight lines AP^1, CP^1, and BP^1.
6. $AP^1 = P^1B$, $AC = CB$, $P^1C = P^1C$. 6. Assumed in 5. Hyp. Identical.
7. $\therefore \triangle AP^1C \cong \triangle BP^1C$. 7. Theorem 9, §77.
8. $\therefore \angle P^1CA = \angle PCB =$ a rt. $\angle$. and P^1C is $\perp$ AB at C. 8. Corresponding parts of congruent triangles, §68. Def. §35.
9. $\therefore$ Lines PC and P^1C coincide, P^1 must be on CP. 9. Pos. §18.

Second Method.



5. Let P^1 be a point which is not on CP^1, then draw AP^1, BP^1 and CP^1.
6. P^1C cannot be $\perp$ AB at C $\angle ACP^1$ cannot equal $\angle BCP^1$. 6. Pos. §18. Def. §35.
7. Consider the $\measuredangle ACP^1$ and BCP^1, 7.
$AC = CB$, Hyp.
$P^1C = P^1C$, Identical.
$\angle P^1CB > \angle P^1CA$. Reason in 6.
8. $P^1B > P^1A$. 8. Theorem 7. §75.

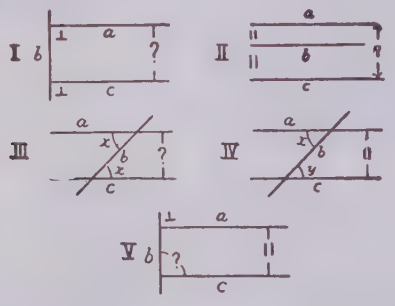
Hence any point P^1 not on PC is not equidistant from A and B.

90. Distance from a Point to a Line.—(Theorem 12, §82. The perpendicular is the shortest distance that can be drawn from a point to a line.) This is defined to be the distance from the point to the line.

91. Theorem 17.—

The locus of points equidistant from the sides of an angle is the bisector of the angle.

Hyp. OC is the bisector of the angle AOB.



Con. OC is the locus of all points equidistant from OA and OB.

1. Let P be any point such that its distance PB from the line OB equals its distance PA from the line OA. Draw OP. 1. Def. §90.
2. In $\measuredangle OAP$ and OPB, 2.
$OP = OP$, Identical.
$PA = PB$, Assumed in 1.
$\angle PBO = \angle PAO =$ a rt. $\angle$. Def. §90.

3. $\therefore \triangle OAP \cong \triangle OBP$.	3. Theorem 15, §87.
4. $\therefore \angle AOP = \angle BOP$.	4. Corresponding angles of congruent triangles §68.
5. $\therefore$ OP coincides with OC, for an angle has but one bisector.	5. Ax. §42.
We now know that every point equidistant from OA and OB as P is on the bisector OC.	
It remains to prove that every point on the bisector is equidistant from OB and OA.	
6. Let P be considered as any point on OC and draw the $\perp$s PA and PB to OA and OB respectively, meeting them in A and B.	
7. Consider $\triangle$OAP and OBP,	7.
$\angle POA = \angle POB$,	Hyp.
$OP = OP$.	Identical.
8. Place $\triangle OBP$ on $\triangle OAP$ so that $\angle POB$ coincides with its equal $\angle POA$, with line OB falling on OA and line OP falling on OP.	8. Pos. §14.
Since $OP = OP$, O and P will remain fixed.	
9. PB will coincide with PA.	9. Theorem 11, §81.
10. $\therefore$ PB = PA.	10. Corresponding parts of congruent triangles.
And every point as P on OC is equidistant from A and B.	

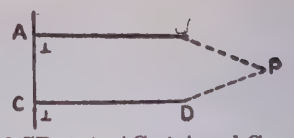
PARALLELS AND PARALLELOGRAMS.

92.—There are many propositions in geometry which have to do with the relations of three objects to each other. If we are given three objects a, b, and c, they can be formed into pairs in three ways, a, b; b, c; and a, c. When we know the relations existing between the elements of two of the pairs, the problem is to find the relation between the two elements of the third pair. We shall give a few examples below, and the reader is advised to study the situation as indicated in each drawing as they are all important geometrical theorems.

It is a sine qua non of geometry to recognize these theorems at once. In each case we have three lines given which are denoted by a, b, and c.

Case I. Line a is perpendicular to line b, line b is perpendicular to line c; the question is the relation of a to c. In symbols, $a \perp b$, $b \perp c$, b ? c. The answer is given in the theorem—Two straight lines perpendicular to the same straight line are parallel.

Case II. Line a is parallel to line b, line b is parallel to line c, the question is the relation of line a to line c. In symbols a $\parallel$ b, b $\parallel$ c, a ? c. The answer is given in the theorem,—Two straight lines parallel to the same straight line are parallel to each other.



Case III. Line a forms the angle x with the line b, line c forms an angle equal to x with the line b; the question is the relation of line a to line c. The answer is given in the theorem,—When two straight lines are cut by a third, if a pair of corresponding angles are equal, the lines are parallel.

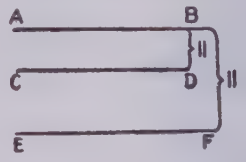
Case IV. Line a is parallel to line c, line b forms an angle x with the line a, line b forms an angle y with the line c; the question is the relation of angle x to angle y. The answer is the theorem,—If two parallel lines are cut by a third line, any two corresponding angles are equal.

Case V. a $\perp$ b, a $\parallel$ c, b ? c. The answer is the theorem,—If a straight line is perpendicular to one of two parallel lines, it is perpendicular to the other.

93. Theorem 18.—

Two straight lines perpendicular to the same straight line are parallel.

Hyp. AB and CD $\perp$ to AC at A and C respectively.



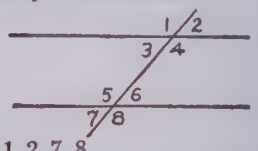
Con. AB $\parallel$ CD.

1. There are only two possibilities, either AB is $\parallel$ CD or AB is not $\parallel$ CD. Suppose that AB meets CD, when they are prolonged, in a point P.	1. §73. There are only two possibilities.
2. This is impossible as we would have two perpendiculars from a point to a line.	2. §81, Theorem 11. From a given point without an unlimited straight line one perpendicular, and only one, can be drawn to the line.
3. $\therefore$ AB $\parallel$ CD.	

94. Reductio ad absurdum.—The above proof is a sample of the proof called by some "reductio ad absurdum." It shows that any other assumption than the given one leads to an absurdity, which in geometry means to a violation of one of the postulates or axioms.

95. Theorem 19.—

Two straight lines parallel to the same straight line are parallel to each other.



Hyp. CD and EF $\parallel$ AB.

Con. CD $\parallel$ EF.

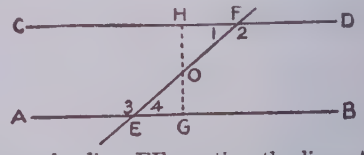
1. Either CD is $\parallel$ EF or CD is not $\parallel$ EF.	1. §73. There are only two possibilities.
2. If CD is not $\parallel$ EF, suppose they meet in a point P, then there are two lines through P $\parallel$ AB, which is impossible.	2. §15. Pos. Through any point outside a given line, one line, and only one, can be drawn parallel to the given line.
3. Hence CD $\parallel$ EF.	

96. Transversal.—A transversal is a line cutting two or more lines.

97. Angles Formed by a Transversal.—

Exterior angles 1, 2, 7, 8.

Interior angles 3, 4, 5, 6.



Alternate-interior angles, there are two pairs 3, 6; 4, 5.

Alternate-exterior angles, there are two pairs 1, 8; 2, 7.

Corresponding angles, there are four pairs 1, 5; 2, 6; 3, 7; 4, 8.

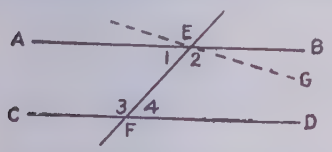
98. Theorem 20.—

When two straight lines are cut by a third, if the alternate interior angles are equal, the two straight lines are parallel.

Hyp. Given the line EF meeting the lines AB and CD in E and F respectively, forming the pairs of alternate interior angles 1, 4 and 2, 3, so that $\angle 1 = \angle 4$ and $\angle 3 = \angle 2$.

Con. Line AB is parallel to line CD.

1. Bisect EF and through the point of bisection O draw OH $\perp$ CD, meeting CD in H and AB in G.	1. §67. §81, Theorem 11.
2. Consider $\triangle$OEG and OHF	2.
OF = OE,	Construction.
$\angle 1 = \angle 4$,	Hypothesis.
$\angle EOG = \angle FOH$,	§80, Theorem 10.
$\therefore \triangle OEG \cong \triangle OHF$.	§65, Theorem 2.
3. OG $\perp$ AB or HG $\perp$ AB, since $\angle OHF = \angle OGE$.	3. Corresponding angles of congruent triangles.
4. HG $\perp$ CD.	4. Construction.
5. $\therefore$ CD $\parallel$ AB.	5. §93, Theorem 18.



99. Theorem 21.—
When two straight lines are cut by a third, if a pair of corresponding angles are equal, the lines are parallel.

In referring to the figure of §97, it will be seen the equality of corresponding angles always demands the equality of the alternate interior angles, so the theorem follows from theorem 20.

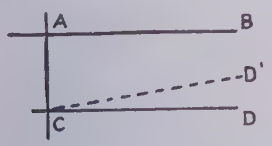
100. Theorem 22.—
When two straight lines are cut by a third, if the sum of two interior angles on the same side of the transversal is equal to two right angles, the two lines are parallel.

Again referring to the figure of §97, if $4+6=$ two right angles, since $3+4=$ two right angles, then $3+4=4+6$ or $3=6$. Thus again we are brought to the equality of alternate interior angles.

101. Theorem 23.—
If two parallel lines are cut by a third line, the alternate interior angles are equal.

Hyp. Two parallel lines AB and CD are cut by the line EF in the points E and F respectively, forming the pairs of alternate interior angles 1 and 4, 2 and 3.

Con. $1=4$ and $2=3$.



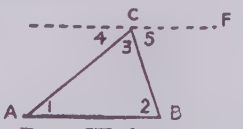
Hint. Draw the line EG through E so that $\angle GEF=3$, then EF meets CD and EG, so as to form equal alternate interior angles, and EG is parallel to CD. (§98, Theorem 20. When two straight lines are cut by a third, if the alternate interior angles are equal, the two straight lines are parallel.) But EG must coincide with AB, otherwise there are two lines through E parallel to CD, but this is impossible. (§15. Postulate. Through any point outside a given line, one line, and only one, can be drawn parallel to the given line.) $\therefore \angle GEF=2=3$.

102. Theorem 24.—
If two parallel lines are cut by a third straight line, any two corresponding angles are equal.

103. Theorem 25.—
If two parallel lines are cut by a third straight line, any two corresponding angles are equal.

Both these theorems follow at once from §101 using the figure and definitions of §97.

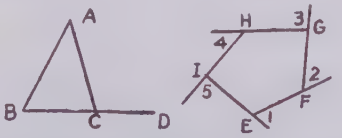
104. Theorem 26.—
If a straight line is perpendicular to one of two parallel lines it is perpendicular to the other.



Hyp. AB parallel to CD and AB perpendicular to AC at A. CD meets AC in C.

Con. CD is perpendicular to AC at C.

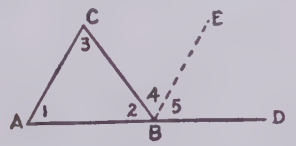
Hint. Through C draw CD^1 perpendicular to AC, then AB is parallel to CD^1. (§93, Theorem 18. Two straight lines perpendicular to the same straight line are parallel.) Then CD and CD^1 coincide. (§15, Postulate. Through any point outside a given line, one line, and only one, can be drawn parallel to the given line.)



105. Theorem 27.—
If the sides of one angle are parallel respectively to the sides of another, the angles are either equal or supplementary. This follows at once from §101, §102, §103.

106. Theorem 28.—
The sum of the angles of any triangle is a straight angle.

Hint. Draw CF through C parallel to AB. Then $1=4$, $2=5$ alternate interior angles. $4+3+5=$ a straight angle, replacing 4 by its equal 1 and 5 by its equal 2 we have $1+2+3=$ a straight angle.

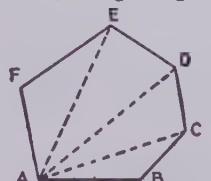


This is an important theorem. We may make the sides of a triangle vary as we please as long as the sum of any two sides is greater than the third, but the sum of the angles of a triangle is always the same. To know two angles of a triangle is the same as knowing all three; hence if two angles of one triangle are equal to two angles of another, the third angle of the first is equal to the third angle of the second.

107. Exterior Angle.—If a side of a triangle as BC is prolonged through a vertex C to a point D, the angle ACD is called an exterior angle of the triangle. Each triangle has six exterior angles, each side can be prolonged in two directions.

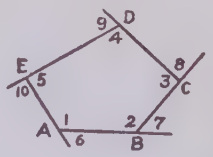
In the case of the polygon EFGHI, exterior angles are obtained by prolonging the sides in the same manner as for a triangle. 1, 2, 3, 4, 5 are one set of exterior angles, another set can be obtained by prolonging the sides in the opposite direction.

108. Theorem 29.—
Any exterior angle of a triangle is equal to the sum of the two opposite interior angles.



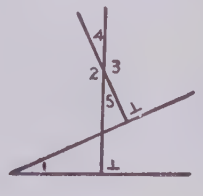
Hyp. AF, a side of the triangle ABC, is prolonged through B to a point D, giving the exterior angle CBD.

Con. $\angle CBD=\angle 1+\angle 3$.



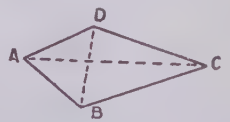
Hint. Draw BE through B parallel to AC. $3=4$ and $1=5$, therefore $1+3=4+5=\angle CBD$.

109. Theorem 30.—
The sum of the angles of a polygon of n sides is (n—2) straight angles.

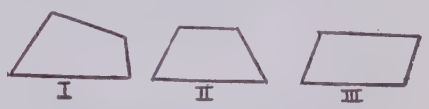


Hint. Study the number of triangles that a polygon of n sides can be cut into and remember that the sum of the angles of each triangle is one straight angle.

110. Theorem 31.—
The sum of the exterior angles of a polygon, made by producing each of its sides in succession, is equal to two straight angles.



By the previous theorem $1+2+3+4+5=$ (n—2) straight angles. At each vertex the sum of the interior and exterior angles is one straight angle, i.e., at A we have $1+6=$ a straight angle. Hence $(1+6)+(2+7)+(3+8)+(4+9)+(5+10)=$ n straight angles. Subtracting the first equation from the second $6+7+8+9+10=$ n straight angles—(n—2) straight angles $=2$ straight angles.



111. Theorem 32.—
If the sides of one angle are perpendicular respectively to the sides of another, the angles are either equal or supplementary.

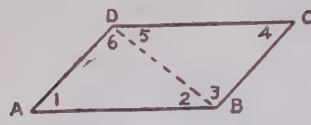
From a drawing it is evident that $1=5=4$, but 1 is supplementary to both 2 and 3.

112. A quadrilateral is a portion of a plane bounded by four straight lines. The lines AB, BC, CD, DA are called the sides. The points A, B, C, D the vertices. The lines AC and BD joining the opposite vertices in pairs are the diagonals.

A trapezium is a quadrilateral no two of whose sides are parallel, I.

A trapezoid is a quadrilateral with two and only two sides parallel, II.

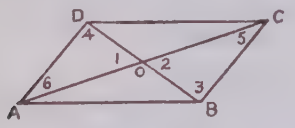
A parallelogram is a quadrilateral whose opposite sides are paralled, III.



A rhomboid is a parallelogram whose angles are not right angles, and whose adjacent sides are unequal, I.

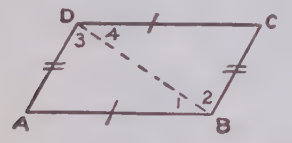
A rhombus is a parallelogram whose angles are not right angles, and whose adjacent sides are equal, II.

A rectangle is a parallelogram whose angles are right angles, III.



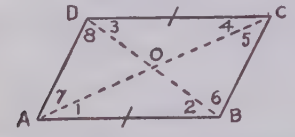
A square is a rectangle whose sides are equal, IV.

113. Theorem 33.—
The opposite sides of a parallelogram are equal, and the opposite angles are equal.



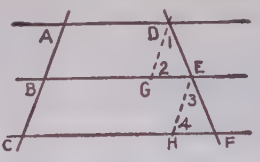
Hint. Draw the diagonal BD. Prove triangle ABD congruent to triangle BCD. (§65, Theorem 2. If two triangles have a side and the two adjoining angles of one respectively equal to a side and two adjoining angles of the other, the triangles are congruent). Hence DC equals AB, CB equals DA, and angle A equals angle C.

114. Theorem 34.—
The diagonals of a parallelogram bisect each other.



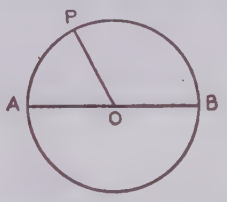
Hint. Prove triangles OAD and OBC congruent. AD = BC, 4 = 3, and 6 = 5. (§65, Theorem 2. If two triangles have a side and two adjoining angles of one respectively equal to a side and two adjoining angles of the other, the triangles are congruent.) Hence OB = OD and OA = OC.

115. Theorem 35.—
If the opposite sides of a quadrilateral are equal, the figure is a parallelogram.



Hint. Draw the diagonal BD. Triangles ABD and BCD are congruent. (§77, Theorem 9. If two triangles have the three sides of one respectively equal to the three sides of the other, the triangles are congruent.) Hence the alternate interior angles 1 and 4 are equal and AB and DC are parallel. (§98, Theorem 20. When two straight lines are cut by a third, if the alternate interior angles are equal, the two straight lines are parallel.) In the same way since 2 = 3, the sides AD and BC are parallel.

116. Theorem 36.—
If two opposite sides of a quadrilateral are equal and parallel, the figure is a parallelogram.



Hyp. AB and DC are parallel and equal.
Con. ABCD is a parallelogram.
Hint. Draw the two diagonals meeting at O. Prove triangles AOB and ODC congruent, then prove triangles OAD and OBC congruent. Then since the alternate interior angles 5 and 7 are equal the sides AD and BC are parallel.

117. Theorem 37.—
If a series of parallel lines cut off equal segments on one transversal, they cut off equal segments on any other transversal.

Hyp. The parallel lines AD, BE, CF cut off equal segments on AC or AB = BC.
Con. The parallel lines cut off equal segments on DF or DE = EF.
Hint. Draw through D, DG parallel to AB and through E, EH parallel to BC. Then ABGD and BCHE are parallelograms, hence DG = AB = BC = EH. Prove the triangles DGE and EHF congruent, 1 = 3, 2 = 4, and DG = EH. Therefore DE = EF corresponding sides of congruent triangles.

The Circle and the Measure of Angles.

118. Circle.—A circle is the curved line passing through all points in a plane which are at a given fixed distance from a fixed point of the plane. When there is no ambiguity a circle can be designated by its center.

119. Center of a Circle.—The fixed point is the center.

120. Radius.—A radius of a circle is a straight line drawn from the center to any point of the circle and is equal to the given fixed distance.

121. Diameter.—A diameter is a straight line passing through the center of the circle and having its two extremities on the circle.
In the above figure O is the center, OA and OB are radii, and AB is a diameter.

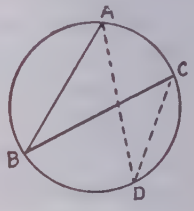
122. Circumference.—The length of a circle is the circumference. It is the distance traversed by a point in making a complete circuit of a circle.
Note. The word circle has two distinct meanings in ordinary language. We may mean the area bounded by the circumference or we may mean only the circumference itself. It is better, from the geometrical standpoint, to understand the circle to be a curved line and not the surface bounded by the line.
Note. A circle can be defined in terms of its locus properties, §88. A circle is the locus of points in a plane at a given fixed distance from a fixed point. When we choose a center and a radius we divide the points of the plane into three classes: (a) those which are at a greater distance from the center than the radius, and which are said to be outside the circle, (b) those which are at a lesser distance from the center than the radius, and which are said to be inside the circle: (c) those which are at the given distance and which constitute the circle itself.

123. Arc.—An arc is a continuous portion of a circle. AP is an arc.

124. Semicircle.—A semicircle is an arc which is half of a circle.

125. Major Arc.—An arc greater than a semicircle is a major arc.

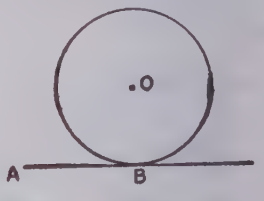
126. Minor Arc.—An arc less than a semicircle is a minor arc.
If we choose two points as P and B, there are two arcs which have these for end points. A minor arc is described by a point which starts at P and moves clockwise to B, a major arc by a point which starts at P and moves counter clockwise to B. The addition of a point in the major arc will do away with this ambiguity, thus PB denotes the minor arc and PAB the major arc.



127. Central Angle.—A central angle is the angle formed by the radii of a circle. Since all radii pass through the center the vertex of a central angle is always at the center. Angle POB is a central angle.

128. Intercept and Subtend.—An angle is said to intercept an arc included between its sides and the arc is said to subtend the angle.
The angle POB intercepts the arc PB and the arc PB subtends the angle POB. Two parallel lines can also cut a circle in two pairs of points, thus they are said to intercept two arcs.

129. Chord.—A chord is a straight line joining the extremities of an arc, the chord is said to subtend the arc. Draw the line PB and you have a chord subtending the arc PB.

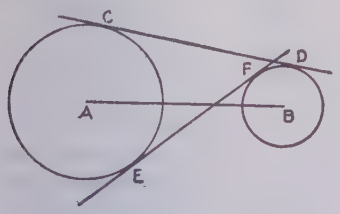


130. Segment.—A segment is a portion of the plane bounded by an arc of a circle and its chord.

131. Sector.—A sector of a circle is a portion of the plane included between an arc and the radii drawn to its extremities. The radii OA and OP with the arc AP bound a sector.

132. Inscribed Angle.—An angle whose vertex is on a circle and whose sides are chords is called an inscribed angle. Angle ABC is an inscribed angle. An angle is inscribed in a segment when its vertex lies on the arc of the segment and its extremities pass through the ends of the segment. Angles ABC and ADC are two angles inscribed in the same segment, the segment denoted by ABC, ADC or ABDC.

133. Concentric Circles.—Circles are concentric when they have the same center.



134. Tangent.—A straight line is said to be tangent to, or to touch a circle when it has but a single point in common with the circumference no matter how far the line is extended. The circle is also said to be tangent to the line. Line AB is tangent to the circle with center at O.

135. Point of Contact.—The single point which a line and circle have in common is called the point of contact.

136. Secant.—A straight line meeting a

circumference in two points is a secant.

137. Tangent Circles.—When two circles are tangent to the same line at the same point they are said to be tangent to each other or tangent circles. They are tangent internally or externally according as one circle lies entirely within or entirely without the other.

138. Common Tangent.—A line which is tangent to two circles is called a common tangent. An internal tangent as EF passes between the two circles. A tangent which does not pass between the circles is called an external tangent.

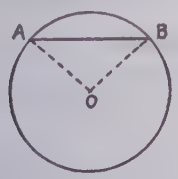
139. Line of Centers.—The line joining the centers of two circles is called the line of centers.

The following statements follow easily from the postulates and axioms.

140.—All radii of a circle are equal, also all diameters are equal.

141.—Two circles are congruent when their radii or diameters are equal.

142.—Two radii or diameters of equal circles are equal.



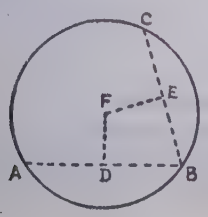
143.—Every diameter bisects the circle and its circumference.

144.—If the centers of two equal circles which lie in the same plane be made to coincide, the circles will coincide.

145.—A radius is equal to one half a diameter.

146. Theorem 38.—

The diameter of a circle is greater than any other chord.



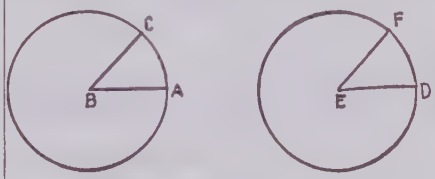
Hyp. AB is any chord of the given circle.

Con. AB is less than a diameter.

Draw the radii OA and OB. OA+OB >AB. (Postulate, §12. A straight line is the shortest distance between two points.) OA+OB is equal to a diameter. ∴ AB is less than a diameter.

147. Theorem 39.—

Through three points not lying in a straight line one circle, and only one, can be drawn.



Hyp. Given the three points A, B, and C not in a straight line.

Con. One circle and only one can be drawn through A, B, and C. Imagine a circle drawn through A, B, and C and let F be the center of this circle. Then AF=BF=CF since they are radii of the same circle. Hence F must be on the perpendicular bisector of AB. (§89. The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.) By the same reasoning F must be on the perpendicular bisector of CB. Hence F is the point of intersection of the perpendicular bisectors DF and EF. These two lines must intersect since if they do not they are parallel which means that A, B, and C are in a straight line. This proves that one center exists. There can not be more than one center because the two bisectors can only intersect in a single point.

148. Theorem 40.—

If in the same circle or in equal circles, two angles at the center are equal, the arcs which they intercept are equal.

Hyp. Given the two equal circles with the centers B and E, with the angles B and E equal, which intercept the arcs AC and DF respectively.

Con. The arc AC equals the arc DF.

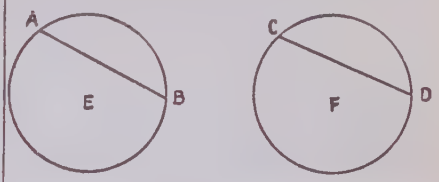
Place the circle with center D on the circle with center B so that the angle B coincides with its equal E. Then the two circles will coincide and the point A will coincide with D and the point C with the point F. Hence AC will coincide with DF, the two end points of an arc determine the arc. If the angles are in the same circle, one angle can be rotated until it coincides with the other.

Note. Many theorems in plane geometry contain the expression "in the same circle or equal circles." The shortest distance between any two points on the surface of a sphere is the arc of a certain circle passing through the two points and this circle always has the same radius no matter what two points are chosen so the theorems are at once useful for different circles on the sphere. When we speak of the distance between New York and London we do not mean the straight line distance but the distance measured along the circumference of a circle drawn on the earth joining the two points. Also when we compare the distances between two pairs of places we are comparing arcs of two different equa/ circles.

149. Theorem 41.—

If in the same circle, or in equal circles, two arcs are equal, the angles which they subtend at the center are equal.

The figure of theorem 40 can be used.



Hyp. Arcs AC and FD, drawn in the equal circles, are equal.

Con. Angles B and E are equal.

The proof is by superposition. Make the two circles coincide with the arcs AC and DF coinciding, then show that the angles B and E coincide. If the arcs are in the same circle make them coincide by a rotation.

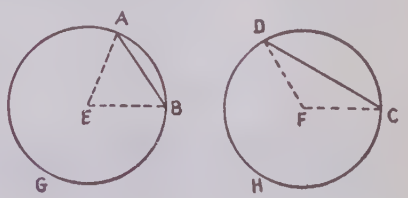
150. Theorem 42.—

If in the same circle, or in equal circles, two arcs are equal the chords subtending them are equal.

Hyp. Given the equal circles E and F with the equal arcs AB and CD respectively.

Con. Chord AB equals the chord CD. The proof is by superposition.

151. Theorem 43.—



If in the same circle, or in equal circles, two chords are equal, the arcs subtended by them are equal. This is the converse of the previous theorem and the same method of superposition can be used.

Hyp. The chord AB equals the chord CD.

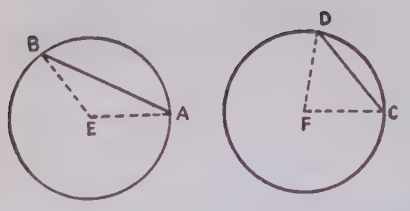
Con. The arc AB equals the arc CD.

152. Theorem 44.—

If in the same circle or in equal circles, two arcs, each less than a semicircle, are unequal, the chords subtending them are unequal; and the greater arc is subtended by the greater chord.

Hyp. Given the equal circles E and F with the unequal arcs AB and CD respectively, with minor arc DC greater than minor arc AB.

Con. Chord DC is greater than the chord AB.



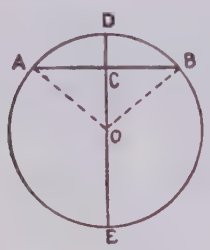
Draw the radii, EB, EA, FC, and FD. If the two circles are made to coincide, with FC coinciding with EB, then since arc DC is greater than arc BA, angle CFD is greater than angle BEA.

Consider the two triangles BEA and CFD. EB=EA=FC=DF, radii of the same or equal circles, but angle CFD is greater than angle BEA. (§75. If two triangles have two sides of one respectively equal to two sides of the other, and the included angles unequal, the triangle which has the greater included angle has the greater third side.) Hence DC is greater than BA.

Note. If we use the arcs which are greater than a semicircle as BGA and CHD, then the greater arc corresponds to the lesser chord.

153. Theorem 45.—

If in the same circle, or in equal circles, two chords are unequal, the arcs subtending them are unequal; and the greater chord subtends the greater arc, provided neither arc exceeds the semicircle.



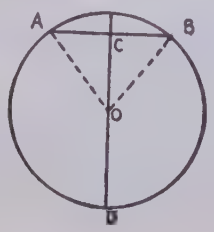
Hyp. Given the equal circles E and F with the chords AB and CD unequal and with AB greater than CD.

Con. Minor arc BA is greater than minor arc CD.

Draw the radii EA, EB, FC, and FD, which are all equal. Consider the triangles EAB and FCD. (§76. Theorem 8. If two triangles have two sides of one respectively equal to two sides of the other, and the third sides unequal, the triangle which has the greater third side has the greater included angle.) Therefore angle AEB is greater than angle CFD. Evidently the greater angle corresponds to the greater arc.

154. Theorem 46.—

The diameter perpendicular to a chord bisects the chord and the arcs which the chord subtends.

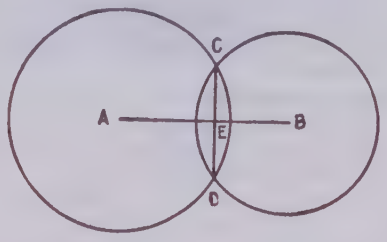


Hyp. The diameter ED is perpendicular to the chord AB, meeting it in the point C, and meeting the minor arc AB in the point D and the major arc AEB in the point E.

Con. AC equals CB, arc AD equals arc DB, and arc AE equals arc EB. Draw the radii OA and OB, which are equal. The right triangles OCA and OCB have OC common and AO equal to OB. (§87. Theorem 15. If two right triangles have the hypotenuse and a leg of one respectively equal to the hypotenuse and a leg of the other, the triangles are congruent.) Hence AC=CB. Also angle AOC equals angle COB. (§148. Theorem. Equal angles at the center subtend equal arcs.) Hence arc AD equals arc DB. Arc DAE equals arc DBE since both are semicircles. Subtracting the equal arcs AD and DB we have arc AE equals arc BE. (§40. Axiom. If equals are subtracted from equals, the remainders are equal.)

155. Theorem 47.—

The perpendicular bisector of a chord passes through the center of the circle.



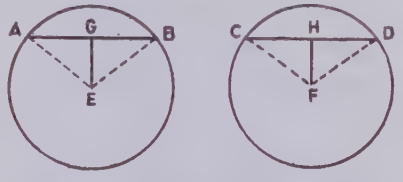
Hyp. CD is the line perpendicular to the chord AB at its mid-point C.

Con. CD passes through O, the center of the circle.

Draw OA and OB radii of the circle. All radii of the same circle are equal, hence OA equals OB, thus O is a point equidistant from A and B. (§89. Theorem 16. The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.) Therefore O is on CD.

156. Theorem 48.—

When two circles intersect each other the straight line through their centers is the perpendicular bisector of their common chords.



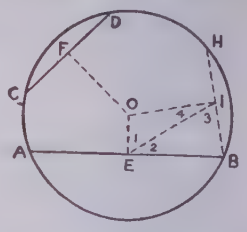
Hyp. The two given circles A and B intersect in C and D. CD is the common chord and AB the line of centers, intersecting in the point E.

Con. AB is the perpendicular bisector of CD.

If AB is not the perpendicular bisector of AB, draw the line perpendicular to CD at its midpoint. By the previous theorem, the line just drawn will pass through the centers of both circles, hence through the points A and B. Hence AB is the perpendicular bisector of AB. (§8. Postulate. One straight line, and only one, can be drawn through two given points.)

157. Theorem 49.—

If in the same circle, or in equal circles, two chords are equal, they are equally distant from the center.



Hyp. Given the equal circles E and F with the equal chords AB and CD respectively. EG and FH the perpendiculars from the centers on their respective chords.

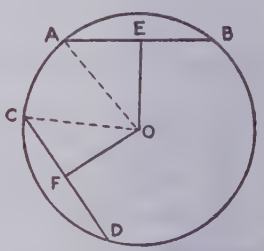
Con. EG equals HF.

Draw the radii FA and FC, which are equal. (§154. Theorem 46. The diameter perpendicular to a chord bisects the chord and the arc which the chord subtends.) Hence AG=½AB and CH=½CD but by hypothesis AB=CD, therefore AG=CH. (§46. Postulate. Quantities that are equal to the same quantity or to equal quantities are equal to each other.) Consider the right triangles AGE and CHF. (§87. Theorem. If two right triangles have a leg and the hypotenuse of one equal to a leg and the hypotenuse of the other, the triangles are congruent.) Therefore AGE and CHF are congruent and GE equals FH. The case where they are chords of the same circle permits of the same proof.

158. Theorem 50.—

If in the same circle, or in equal circles, two chords are unequal, the greater chord is at the less distance from the center.

Hyp. Chord AB is greater than the chord DC. OE is the perpendicular from O on AB, meeting it in E, and OF the perpendicular from O and CD, meeting it in F.

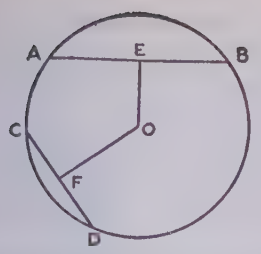


Con. OF is greater than OE.

Let BH be a chord equal to CD and let OI be the perpendicular from O on BH, meeting it in I. By the previous theorem OI equals OF. Draw EI. EB=½AB and BI=½BH. Since AB is greater than CD or its equal BH, EB is greater than BI. (§44. Axiom. If unequals are operated on by positive unequals in the same way, the results are unequal in the same order.) In the triangle EBI angle 3 is greater than angle 2. (§74. Theorem. If one side of a triangle is greater than a second side, the angle opposite the first side is greater than the angle opposite the second side.) $\angle 4+\angle 3=$ a right angle, $\angle 1+\angle 2=$ a right angle, therefore $\angle 1+\angle 2=\angle 3+\angle 4$. But $\angle 2<\angle 3$ therefore $\angle 4<\angle 1$. (§45, Axiom. If unequals are subtracted from equals the remainders are unequal in the reverse order.) Now consider triangle OEI with $\angle 4$ less than $\angle 1$; side OE is less than side OI. (§72. Theorem. If one angle of a triangle is greater than a second angle, the side opposite the first angle is greater than the side opposite the second angle.) If OE is less than OI, then OE is less than OF.

Note. The proof when the chords are in different circles is the same.

159. Theorem 51.—



If in the same circle, or in equal circles, two chords are equally distant from the center, they are equal.

Hint. Prove that the two right triangles OEA and OCF are congruent. (§87. Theorem 15. If two right triangles have the hypotenuse and a leg of one respectively equal to the hypotenuse and leg of another, the triangles are congruent.)

160. Theorem 52.—

If in the same circle, or in equal circles, two chords are unequally distant from the center, the chord at the less distance is the greater.

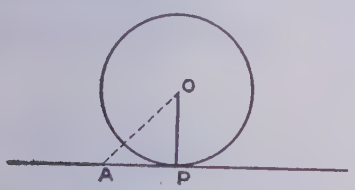
Hyp. OE the perpendicular distance from O, the center of the circle to the chord AB, and OF the perpendicular distance to the chord CD. OF is greater than OE.

Con. AB is greater than CD.

Hint. Use the method of exclusion. There are three possibilities;

(a) AB equal to CD,

(b) AB less than CD,



(c) AB greater than CD.

§157. **Theorem 49.**—If in the same circle, or in equal circles, two chords are equal, they are equally distant from the center. This would require in case (a) that OE equals OF, which is impossible.

§158. **Theorem 50.**—If in the same circle or in equal circles, two chords are unequal, the greater chord is at the less distance from the center. This would require in case (b) that OE was greater than OF. Hence only (c) remains as possible.

161. Theorem 53.—

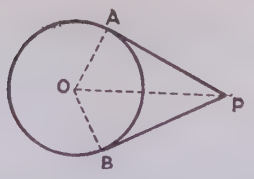
A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact.

Hyp. PA is the tangent to the circle O at the point P.

Con. AP is perpendicular to the radius OP at P.

From the definition of a tangent §134 it follows that the line AP is entirely outside the circle. Take any other point A of the tangent AP and draw AO. Evidently OA is greater than OP, and the least distance from O to AP is OP. Hence OP is perpendicular to AP. (§82. Theorem. The perpendicular is the shortest line that can be drawn from a point to a straight line.)

Note. This shows there is only one tangent to a circle at a given point. (§18. Postulate. From a given point in a given line, one perpendicular, and only one, can be drawn to the line.)

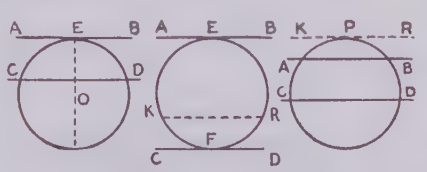


162. Theorem 54.—

A perpendicular to a tangent at the point of contact passes through the center of the circle.

Hint. There is only one tangent at a point and this tangent is perpendicular to the radius drawn to the point of contact by a previous theorem.

163. Theorem 55.—



The tangents drawn to a circle from an external point are equal.

Hint. (§161. Theorem 53. A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact.) Hence A and B are right angles. OA and OB are equal radii of the same circle and OP is common to the two right triangles OPA and OBP. (§87. Theorem 15. If two right triangles have the hypotenuse and a leg of one respectively equal to the hypotenuse and a leg of the other, the triangles are equal.) Therefore AP equals BP.

164. Theorem 56.—

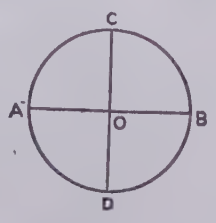
Two parallel lines intercept equal arcs on a circle.

Case I Case II Case III

Case I. Only one of the parallels is tangent to the circle.

Hyp. Given AB tangent to the circle at E and CD parallel to AB meeting the circle in C and D.

Con. Arc EC equals arc ED.

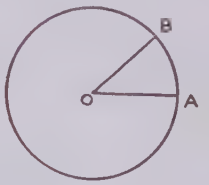


Draw EO which is perpendicular to AB. (§161. Theorem 53. A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact.) Then OE is perpendicular to CD also. (§104. Theorem 26. If a straight line is perpendicular to one of two parallel lines it is perpendicular to the other also.) Arc CE equals ED. (§154. Theorem 46. The diameter perpendicular to a chord bisects the chord and the arcs, which the chord subtends.)

Case II. Both parallels are tangents.

Hint. Draw a line KR parallel to AB and meeting the circle in KR. By case I, arc EK = arc ER, and arc KF = arc FR, add these two equations and we have arc EK + arc KF = arc ER + arc RF or arc EKF = arc ERF.

Case III. Both parallels are secants.

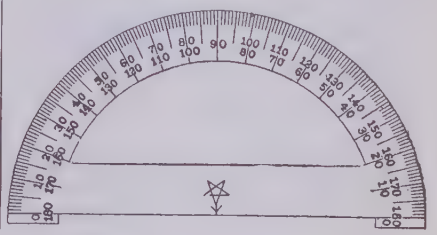


Hint. Draw KR parallel to AB and tangent to the circle at P. Then arc PC = arc PD and arc PA = arc PB, subtract the second equation from the first and we have arc PC − arc PA = arc PD − arc PB or arc AC = arc BD.

165. Measurement of Angles.—If we draw two perpendiculars diameters of a circle as AB and CD we divide the circumference of the circle into four equal arcs AD, BD, BC, and AC and they correspond to the four equal right angles at O. In the same way if we divide the circumference into any number of equal parts and draw the radii to the points of division we will have the same number of equal angles formed at the center of the circle.

166. Degree of Arc.—If the circumference of a circle is divided into 360 equal parts, one of these parts is called a degree of arc. This corresponds to dividing an arc like BC into 90 equal parts.

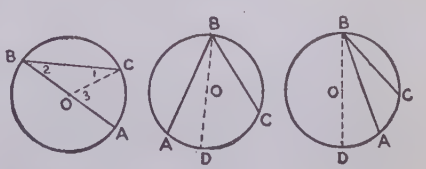
167. Degree.—If a right angle is divided into 90 equal angles, we call each angle an angle of one degree. Symbol °, A right angle = 90°.



Minute.—If a degree is divided into 60 equal angles, each angle is called a minute. Symbol ′. 1° = 60′.

Second.—If a minute is divided into 60 equal angles, each angle is called a second. Symbol ″. 1′ = 60″.

A central angle is measured by its intercepted arc, where the angle is measured in angle degrees and the arc in arc degrees. When we say that AOB = 45°, we mean that ∠AOB is 45/360 of two straight angles or four right angles. When we say the arc AB is 45° we mean it is 45/360 of the circumference of the circle.



The numbers used in the measuring of the angle and the arc which it subtends are chosen so as to be the same for the sake of convenience. If the railroad fare were one cent a mile, then the number giving the miles would be the same as the number giving the cost of a ticket in cents, it does not mean that one cent is the same as one mile.

168. Protractor.—Based on the ideas just explained, the instrument in common use for the measurement of angles is called a protractor and is illustrated above.

169. Theorem 57.—

An angle inscribed in a circle is measured by one half of its intercepted arc.

Case I Case II Case III

Hyp. Given the inscribed angle ABC, intercepting the arc AC.

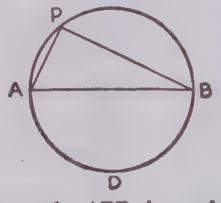
Con. Angle ABC is measured by one half the arc AC.

Case I. When one side passed through the center O.

Draw OC. Then triangle OBC is an isosceles triangle and $\angle 1 = \angle 2$. §69. Theorem. In an isosceles triangle the angles opposite the equal sides are equal.) But $\angle 3$ equals $\angle 1 + \angle 2$. (§108. Theorem. The exterior angle of a triangle is equal to the sum of the two opposite interior angles.) But by the previous section $\angle 3$ is measured by the arc AC, hence $\angle 2$, which is one half of $\angle 3$, is measured by one half the arc AC.

Case II. When the center of O falls inside the angle.

Hint. Draw the diameter BO meeting the circle in D. Then $\angle ABD$ is measured by one half arc AD and $\angle DBC$ is measured by one half the arc DC. Adding, we have $\angle ABC$ measured by one half arc AC.



Case III. When the center O falls outside the angle.

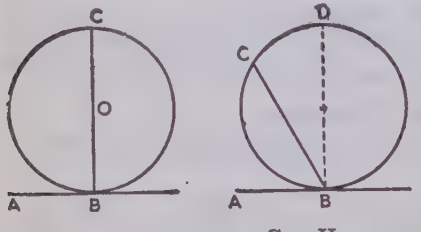
Hint. Draw the diameter BO meeting the circle in D. $\angle ABC = \angle DBC - \angle DBA$. Apply case I to each of these angles.

If AC is 80 arc degrees, then angle B is 40 angle degrees.

170. Theorem 58.—

An angle inscribed in a semi-circle is a right angle.

Hyp. Angle APB is angle inscribed in a semi-circle.



Con. Angle APB is a right angle.

By the previous theorem, APB is measured by one half the arc ADB which is a semi-circle. One half a semi-circle is 90 arc degrees, hence APB is 90 angle degrees.

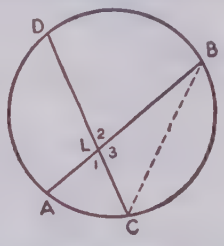
Note. However P moves about the circle the angle APB will always be a right angle. The locus of a point which subtends a right angle with two fixed points is a circle having the two points for the extremities of a diameter.

171. Theorem 59.

An angle formed by a tangent and a chord through the point of contact is measured by one-half the intercepted arc.

Case I Case II

Hyp. Given an angle formed by a tangent at B, AB, and a chord CB.



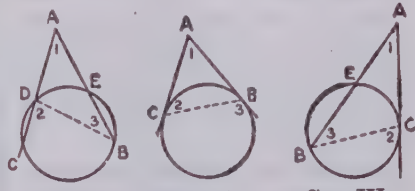
Con. The angle is measured by one-half the intercepted arc.

Case I. BC passes through O, the center of the circle. §161 Theorem 53. A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact. Hence angle ABC is a right angle, or 90°. The intercepted arc BC is 180° arc degrees. Therefore $\angle ABC = \frac{1}{2}$ arc BC.

Case II. BC does not pass through O, the center of the circle. Draw the diameter BO meeting the circle in D. §169 Theorem 57. An angle inscribed in a circle is measured by one-half its intercepted arc. Therefore $\angle CBD = \frac{1}{2}$ arc CD. $\angle ABD = \frac{1}{2}$ arc ACD by Case I. Subtracting $\angle ABC = \frac{1}{2}$ arc BC.

172. Theorem 60.

An angle formed by two chords intersecting each other within a circle is measured by one-half the sum of the arc intercepted between its sides and the arc intercepted between the sides of its vertical angle.



Hyp. Chords AB and CD intersecting in L to form the angle 1 and 2 which are vertical angles.

Con. $\angle 1$ and $\angle 2$ are measured by $\frac{1}{2}$ (arc AC + arc DB).

Draw CB. $\angle 1 = \angle B + \angle C$. (§108. Theorem 29. Any exterior angle of a triangle is equal to the sum of the two opposite interior angles.) $\angle C$ is measured by $\frac{1}{2}$ arc DB and $\angle B$ is measured by $\frac{1}{2}$ arc AC. (§169. Theorem 57. An angle inscribed in a circle is measured by one-half its intercepted arc.) Hence $\angle 1 = \angle 2$, is measured by $\frac{1}{2}$ (arc AC + arc DB).

173. Theorem 61.

An angle formed by two secants, or two tang nts, or a secant and a tangent, intersecting without a circle, is measured by one-half the difference of the intercepted arcs.

Case I Case II Case III

Case I. Hyp. AB and AC are two secants meeting in the point A, outside the circle.

Con. Angle A is measured by $\frac{1}{2}$ (arc BC — arc ED).

Draw DB. $\angle 2 = \angle 3 + \angle 1$. (§108. Theorem. Any exterior angle of a triangle is equal to the sum of the two opposite interior angles.) Therefore $\angle A = \angle 1 = \angle 2 - \angle 3$. $\angle 2$ is measured by $\frac{1}{2}$ arc BC, $\angle 3$ is measured by $\frac{1}{2}$ arc ED (§169. Theorem 57. An angle inscribed in a circle is measured by one-half its intercepted arc). Hence A is measured by $\frac{1}{2}$ (arc BC — arc ED).

Case II. Hint. $\angle 3 = \angle 2 + \angle 1$, therefore $\angle 1 = \angle 3 - \angle 2$.

Case III. Hint. $\angle 2 = \angle 3 + \angle 1$, therefore $\angle 1 = \angle 2 - \angle 3$.

Similar Polygons

We are perfectly familiar in every day life with objects which are just alike except for size. We speak for instance of enlarging a photograph to be two or three times its original size, or of drawing a map to a certain scale so that one inch represents a mile. It will be the purpose of the present chapter to give expression to these ideas in precise gometrical language.

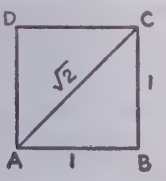
174. Measurement.—The first problem of measurement is that of determining a length. The unit of length must be an arbitrary distance, the straight line distance between two marks on a rod which is fixed as the standard unit.

Each government preserves a platinum rod on which is indicated the standard unit of length and all other units are derived from this by comparison. The French government at the time the metric system was established intended that the unit of length, the meter, should depend upon the size of the earth; but the data upon which the calculations were made have since been found to be incorrect, so that the meter is also an arbitrary distance.

A E F B C D

What do I mean when I say that the rod or line AB is 3 feet long? If I take a rod or line CD, one foot long, and make it coincide with the line AB so that C coincides with A, then D will fall at some point E, and AE will be one foot, repeating the operation on EB, D will fall on some point F, again repeating the operation on FB, if D coincides with B, I say that AB is 3 feet long. When I wish to measure 5 inches, I must divide CD into 12 equal parts and measure off one of these units 5 times.

175. Ratio.—The ratio of one magnitude a to another magnitude b is the quotient resulting from dividing a by b or a/b. It is read, the ratio of a to b. The numerator a is called the antecedent and the denominator b is called the consequent.



176. Relation of Ratio to Measurement.—When we measured the rod AB in §174 we were in reality finding the ratio of AB to the unit length CD, that is $AB/CD = 3$. In finding the value of a geometric ratio it is very important that the two distances are measured in the same units. If we were allowed to measure AB in inches while CD was measured in feet, $AB/CD = 36/1 = 36$. Thus any number of values could be obtained for the ratio, if this essential is neglected. The true value of the ratio is independent of the units used; thus if both AB and CD are expressed in inches $AB/CD = 36/12 = 3$.

177. Difficulties in Measurement. — There are difficulties in an exact treatment of measurement, which correspond to certain complications in our number system. We will illustrate some of these difficulties and show how they are related to measurement.

If we try to express 1/3 as a decimal we have a never ending sequence, $1/3 = .33333\ldots$ which is the same as $3/10 + 3/100 + 3/1000 + 3/10000\ldots$ This means that if we have any numbers of rods 1/10, 1/100, 1/1000 . . of an inch long and take 3 of the 1/10 inch rods, 3 of 1/100 inch rods, 3 of 1/1000 inch rods and place them end

to end we will obtain a length which is only approximately 1/3. No matter how many such rods we take we can never obtain exactly 1/3 of an inch. The mathematician prefers if possible to solve his problem in a definite number of steps. Perhaps we can imagine an infinite number of steps, but life is short and we can actually carry out only a finite number. Of course we can obtain 1/3 of an inch by dividing an inch into 3 equal parts.

But we now come to a difficulty that cannot be dismissed so easily.

If we take a square ABCD with each side one inch, then the length of the diagonal AC is $\sqrt{2}$ inches. What shall we mean by the ratio AC/AB? We should call this $\sqrt{2}$. But how are we to interpret it in terms of measurement? $\sqrt{2} = 1.4142\ldots. = 1+4/10+1/100+4/1000+2/10000\ldots.$ We can take a rod 1 inch long, 4 rods 1/10 inch long, one rod 1/100 inch long, 4 rods 1/1000 inch long, ...put them end to end and obtain an approximation to AC. In the case of 1/3 we could escape the difficulty by trisecting the unit instead of repeatedly dividing it into 10 parts, but there is no such escape here. There is no finite number of parts into which AB can be divided so that their sum will be exactly equal to AC. This is only a theoretical difficulty as it is evident that we can calculate the value of $\sqrt{2}$ as closely as we please. What gives the mathematician concern is that he must use an infinite number of processes to obtain the exact result, and these can only be carried out in the imagination.

178. Commensurable Magnitudes.—Two magnitudes are said to be commensurable when there exists a unit of measure which is contained an integral number of times in each. Lines of length 2 1/3 feet and 4 3/5 feet are commensurable, for $2\ 1/3 = 7/3 = 35/15$ and $4\ 3/5 = 23/5 = 69/15$, thus 1/15 of a foot is contained 35 times in 2 1/3 feet and 69 times in 4 3/5 feet.

179. Incommensurable Magnitudes.—Two magnitudes are said to be incommensurable when there is no unit of measure which is contained an integral number of times in each. As explained in §177, $\sqrt{2}$ and 1 are incommensurable.

180. Proportion.—Four magnitudes a, b, c, and d, are in proportion if the ratio of the first pair equals the ratio of the second. Symbol $a/b = c/d$ or $a:b = c:d$. This is read, a is to b as c is to d or a divided by b equals c divided by d.

There are many different forms that can be derived from the equality $a/b = c/d$ by use of the axioms.

I. Thus if $a/b = c/d$,

$1 = 1$, identity,

$a/b+1 = c/d+1$, §39,

therefore $\frac{a+b}{b} = \frac{c+d}{d}$ reducing to a common denominator. This is called the addition theorem of proportion.

II. Again, if $a/b = c/d$,

Then $bd(a/b) = bd(c/d)$, §41,

Thus $ad = bc$, reducing.

Dividing by cd, $\frac{ad}{cd} = \frac{bc}{cd}$ §42.

Reducing $a/c = b/d$.

This is called the alternation theorem in proportion.

III. Given $\frac{a}{b} = \frac{a_1}{b_1} = \frac{a_2}{b_2} = \frac{a_3}{b_3}$

Con. $\frac{a+a_1+a_2+a_3}{b+b_1+b_2+b_3} = \frac{a}{b} = \frac{a_1}{b_1} = \ldots\ldots\ldots$

Let $\frac{a}{b} = \frac{a_1}{b_1} = \frac{a_2}{b_2} = \frac{a_3}{b_3} = r.$

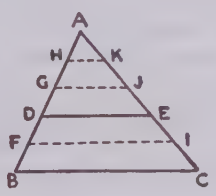
Then $a = br,$
$a_1 = b_1 r,$
$a_2 = b_2 r,$
$a_3 = b_3 r.$

Adding $a+a_1+a_2+a_3 = br+b_1r+b_2r+b_3r,$
$= (b+b_1+b_2+b_3)r.$

$\therefore \quad \frac{a+a_1+a_2+a_3}{b+b_1+b_2+b_3} = r.$

Hence $\frac{a+a_1+a_2+a_3}{b+b_1+b_2+b_3} = \frac{a}{b} = \frac{a_1}{b_1} = \ldots\ldots$

This is called the inversion theorem in proportion. (See Article 255, page 879.)



IV. **Mean Proportional.**—A mean proportional between two magnitudes a and b is the magnitude x defined by $a/x = x/b$, or $x = \sqrt{ab}$.

V. If $a/b = c/d$,
then $b/a = d/c$.

This is called the inversion theorem in proportion.

181. Theorem 62.—

A straight line parallel to the base of a triangle divides the other two sides proportionally.

Hyp. The line DE parallel to the base BC of the triangle ABC meets AB in D and AC in E.

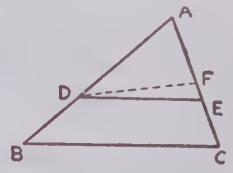
Con. $\frac{AD}{DB} = \frac{AE}{EC}$

First we shall prove the so called commensurable case, that is where it is possible to find a segment as BF which is contained an integral number of times in the two segments BD and DA.

For the sake of clarity we will assume that BF is contained 2 times in BD and 3 times in DA. Let F, G, and H be the points corresponding to the division of the segments into multiples of BF. Then draw through each of the points F, G, and H, lines parallel to BC which meets AC in the points I, J, and K. Then by §117, Theorem 37. (If a series of parallel lines cut off equal segments on one transversal they cut off equal segments on any other transversal.) $CI = IE = EJ = JK = KA$

Hence $\frac{AD}{BD} = \frac{3(BF)}{2(BF)} = \frac{3}{2}$, and $\frac{AE}{EC} = \frac{3(IC)}{2(IC)} = \frac{3}{2}$

Therefore $\frac{AD}{BD} = \frac{AE}{EC}$, (§46, Axiom. Things equal to the same things are equal to each other).



The proof of the incommensurable case goes beyond the work in a first reading of geometry.

It follows also by the method of §180, that $\frac{AD}{AB} = \frac{AE}{AC} = \frac{3}{5}$.

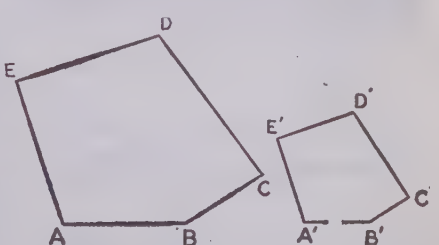
182. Theorem 63.

If a straight line divides two sides of a triangle proportionally, it is parallel to the third side.

This is the converse of the previous theorem.

Hyp. DE meets the sides AB and AC of the triangle ABC in the points D and E respectively, so that $\frac{AD}{DB} = \frac{AE}{EC}$

Con. DE is parallel to BC.



DE is either parallel to BC or it is not.

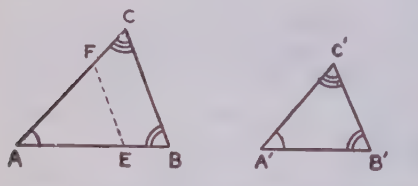
If it is not parallel, draw DF parallel to BC through D, meeting AC in F; but by the previous theorem, $\frac{AD}{DB} = \frac{AF}{FC}$ or $\frac{AD}{AB} = \frac{AF}{AC}$.

But if $\frac{AD}{DB} = \frac{AE}{EC}$ then $\frac{AD}{AB} = \frac{AE}{AC}$ by the previous theorem. Hence $\frac{AE}{AC} = \frac{AF}{AC}$ (§46 Axiom. Things equal to the same things are equal to each other.) Then $AE = AF$ (§41 Axiom. If equals are multiplied by equals the products are equal.) Therefore E coincides with F.

183. Polygon.—A polygon is a plane figure bounded by three or more straight lines. A polygon bounded by three lines is a triangle, one bounded by four lines is a quadrilateral, one bounded by five a pentagon, one bounded by six a hexagon, etc.

184. Convex and Reentrant Polygons.—A polygon is convex if each of its angles is less than two right angles and reentrant if one of its angles exceeds two right angles.

185. Similar Polygons.—Two polygons are similar (symbol ∼) when the angles of one are equal respectively to the angles of the other and the sides taken in order are proportional each to each. The conditions which must be satisfied in order that the two polygons ABCDE and $A^1B^1C^1D^1E^1$ may be similar are:



Angles equal $\angle A = \angle A^1$, $\angle B = \angle B^1$.

$\angle C = \angle C^1$, $\angle D = \angle D^1$, $\angle E = \angle E^1$,
Sides proportional

$$\frac{AB}{A^1B^1} = \frac{BC}{B^1C^1} = \frac{CD}{C^1B^1} = \frac{DE}{D^1E^1} = \frac{EA}{E^1A^1}$$

186. Theorem 64.—

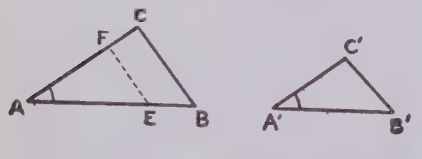
If two triangles have the angles of one respectively equal to the angles of the other, the triangles are similar.

Hyp. Given the triangles ABC and $A^1B^1C^1$ with $\angle A = \angle A^1$, $\angle B = \angle B^1$ and $\angle C = \angle C^1$.

Con. $\frac{AB}{A^1B^1} = \frac{BC}{B^1C^1} = \frac{CA}{C^1A^1}$

Since $\angle A = \angle A^1$ it is possible to place triangle $A^1B^1C^1$ on ABC so that A^1B^1 takes the position AE, A^1C^1 the position AF, and B^1C^1 the position EF. Then FE is parallel to BC. (§99, Theorem 21. When two straight lines are cut by a third, if a pair of corresponding angles are equal, the lines are parallel.) Since $\angle E = \angle B^1 = \angle B$.

Then $\frac{AE}{AB} = \frac{AF}{AC}$, (§181, Theorem 62, A straight line parallel to the base of a triangle divides the other two sides proportionally.) Replace AE and AF by their equals A^1B^1 and A^1C^1 respectively we have $\frac{A^1B^1}{AB} = \frac{A^1C^1}{AC}$. The theorem can be completed by causing angle B^1 to coincide with B.



187. Theorem 65.—

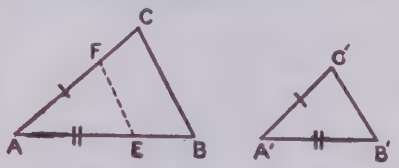
If two triangles have two angles of one respectively equal to two angles of the other, the triangles are similar.

This follows at once from the previous theorem, for if two angles of one triangle are equal to two angles of another, the third angles are also equal. (§106, Theorem 28. The sum of the angles of any triangle is a straight angle.)

188. Theorem 66.—

If two triangles have an angle of one equal to an angle of the other and the sides including these angles proportional, the triangles are similar.

Hyp. Given the triangles ABC and $A^1B^1C^1$ with $\angle A = \angle A^1$ and $\frac{A^1C^1}{AC} = \frac{A^1B^1}{AB}$



Con. ABC and $A^1B^1C^1$ are similar.

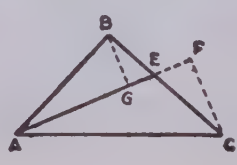
Hint. Place $A^1B^1C^1$ on ABC so that A^1 coincides with its equal A and B^1 takes the position E and C^1 the position F. Then EF divides AC and AB proportionally, which follows from replacing A^1B^1 and A^1C^1 by their equals AB and AF in $\frac{A^1C^1}{AC} = \frac{A^1B^1}{AB}$ to give $\frac{AF}{AC} = \frac{AE}{AB}$. Then FE is parallel to BC. (§182, Theorem 63. If a straight line divides two sides of a triangle proportionally it is parallel to the third side.) Then $\angle F = \angle C = \angle C^1$ and $\angle E = \angle B = \angle B^1$. (§102, Theorem 4. If two parallel lines are cut by a third line any two corresponding angles are equal.)

Hence the three angles of $A^1B^1C^1$ are equal to the three angles ABC and we are led back to the previous theorem. (§186, Theorem 64. If two triangles have the angles of one respectively equal to the angles of the other, the triangles are similar.)

189. Theorem 67.—

If the sides of two triangles are proportional, the triangles are similar.

Hyp. Given the two triangles ABC and $A^1B^1C^1$ with $\frac{AB}{A^1B^1} = \frac{BC}{B^1C^1} = \frac{CA}{C^1A^1}$



Con. The triangles ABC and $A^1B^1C^1$ are similar.

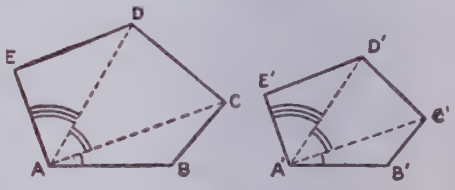
On AC measure off AF equal to A^1C^1 and on AB measure off AE equal to A^1B^1. Replace A^1B^1 and A^1C^1 by their equals AE and AF respectively in $\frac{AB}{A^1B^1} = \frac{AC}{A^1C^1}$ we have $\frac{AB}{AE} = \frac{AC}{AF}$. Hence triangles ABC and AEF are similar. (§188, Theorem 66. If two triangles have an angle of one equal to an angle of the other and the sides including these angles proportional, the triangles are similar.) Hence $\frac{FE}{CB} = \frac{AE}{AB}$ from the definition of similar triangles. Replace AE by its equal A^1B^1 and we have $\frac{FE}{CB} = \frac{A^1B^1}{AB}$, but $\frac{C^1B^1}{CB} = \frac{A^1B^1}{AB}$ by hypothesis. We now have two values for $\frac{A^1B^1}{AB}$, $\frac{FE}{CB}$ and $\frac{C^1B^1}{CB}$, and these are equal to each other. (§46, Axiom. Things equal to the same things are equal to each other.)

Hence $\frac{FE}{CB} = \frac{C^1B^1}{CB}$. Multiply both sides by CB and we have $FE = C^1B^1$. (§41, Axiom. If equals are multiplied by equals, the products are equal.) This shows that the triangle AEF has its three sides equal to those of the triangle $A^1B^1C^1$. Since AEF is similar to ABC its equal $A^1B^1C^1$ is also similar.

190. Theorem 68.—

The bisector of an angle of a triangle divides the opposite side into segments proportional to the adjacent sides.

Hyp. AE is the bisector of the Angle A of the triangle ABC.



Con. $\frac{BE}{AB} = \frac{EC}{AC}$

Prolong AE sufficiently and draw the perpendicular from C to AE, meeting it in F, and draw the perpendicular from B on meeting it in G. Triangles ABG and AFC are similar; $\angle BAG = \angle FAC$ by hypothesis and $\angle G = \angle F$, both right angles. (§187, Theorem 65. If two triangles have two angles of one respectively equal to the angles of the other, the triangles are similar.) Therefore $\frac{AB}{AC} = \frac{BG}{FC}$, definition of similar triangles. $\angle BEG = \angle CEF$, being vertical angles; $\angle F = \angle G$, both being right angles.

Hence, by Theorem 65 quoted above, the triangles BGE and CEF are similar. Therefore $\frac{BG}{FC} = \frac{BE}{EC}$, definition of similar triangles. Equating the equal values for $\frac{BG}{FC}$ we have $\frac{AB}{AC} = \frac{BE}{EC}$.

191. Theorem 69.—

If two polygons are composed of the same number of triangles, similar each to each and similarly placed, the polygons are similar. We shall prove this for the case where the triangles of which each polygon is composed have a vertex in common.

Hyp. Two polygons ABCDE and $A^1B^1C^1D^1E^1$ composed of the same number of triangles which are similar each to each and similarly placed, that is, ABC similar to $A^1B^1C^1$, ACD similar to $A^1C^1D^1$.....

Con. ABCDE is similar to $A^1B^1C^1D^1E^1$.

Hint. The angles of the two polygons are equal because they are either equal angles or the sum of equal angles.

$\frac{A^1B^1}{AB} = \frac{B^1C^1}{BC} = \frac{A^1C^1}{AC}$, since ABC is similar to $A^1B^1C^1$.

$\frac{A^1C^1}{AC} = \frac{C^1D^1}{CD}$, since ACD and $A^1C^1D^1$ are similar.

Therefore $\frac{A^1B^1}{AB} = \frac{B^1C^1}{BC} = \frac{C^1D^1}{CD}$, (§46, Axiom. Things equal to the same thing are equal to each other.)

192. Theorem 70.—

If two polygons are similar, they can be resolved into the same number of triangles, similar each to each and similarly placed.

Hint. Use the figure of the previous theorem, and draw the lines, AC, AD, A^1C^1, and A^1D^1. First prove ABC similar to $A^1B^1C^1$, then ACD similar to $A^1C^1D^1$ and so on.

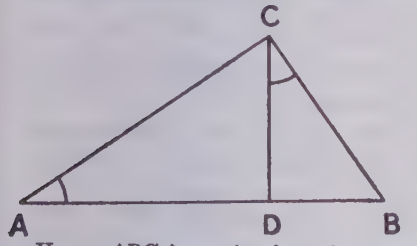
193. Theorem 71.—

The perimeters of two similar polygons are in the same ratio as any two corresponding sides.

Hint. Make use of the figure in theorem 69. From the definition of similar polygons, $\frac{A^1B^1}{AB}=\frac{B^1C^1}{BC}=\frac{C^1D^1}{CD}=\frac{D^1E^1}{DE}=\frac{E^1A^1}{EA}$.

Apply the result of §180, section III to the above gives $\frac{A^1B^1+B^1C^1+C^1D^1+D^1E^1+E^1A^1}{AB+BC+CD+DE+EA}=\frac{A^1B^1}{AB}=\frac{B^1C^1}{BC}=\cdots\cdots\cdots$

or $\frac{\text{the perimeter of P}^1}{\text{the perimeter of P}}=\frac{A^1B^1}{AB}=\frac{B^1C^1}{BC}$



194. Theorem 72.—

If in the right triangle a perpendicular is drawn from the vertex of the right angle to the hypotenuse.

(a) the two triangles thus formed are similar to the given triangle and similar to each other.

(b) the perpendicular is the mean proportional between the segments of the hypotenuse.

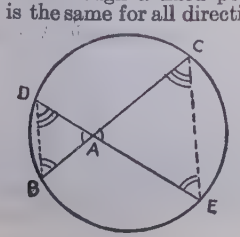
(c) each leg of the right triangle is the mean proportional between the hypotenuse and the segment adjacent to that leg.

Hyp. ABC is a triangle with a right angle at C. From C a perpendicular is dropped on AB, the hypotenuse, meeting it in D.

Con. (a) ADC, BDC, and ABC are similar triangles.

(b) $(CD)^2=(AD)(DB)$. Definition §180, IV.

(c) $(AC)^2=(AB)(AD)$ and $(CB)^2=(AB)(DB)$. Definition §180, IV.



(a). $\angle A$ equals $\angle DCB$. (§111, Theorem. If the sides of one angle are perpendicular respectively to the sides of another, the angles are either equal or supplementary.) Hence the three triangles ABC, DBC, and ABC, have an acute angle equal, a right angle equal and hence all their angles equal. Therefore they are similar. (§187, Theorem 65. If two triangles have the angles of one respectively equal to the angles of the other, the triangles are similar.)

(b). Since the triangles ACD and CBD are similar, from definition we have $\frac{AD}{CD}=\frac{CD}{BD}$. Hence $(CD)^2=(AD)(BD)$.

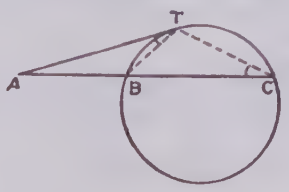
(c). Since the triangles ACD and ABC are similar, from definition we have $\frac{AB}{AC}=\frac{AC}{AD}$. Hence $(AC)^2=(AB)(AD)$. In the same way we can prove that $(CB)^2=(AB)(DB)$.

195. Theorem 73.—

The product of the segments of a chord that passes through a fixed point within a circle is the same for all directions of the chord.

Hyp. Let A be any point within the circle and DE any chord through A.

Con. The product (AE)(AD) is a constant.



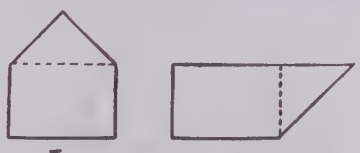
We will prove it a constant by taking any other chord through A as BC showing that (AE)(AD) = (AB)(AC).

$\angle BAD=\angle EAC$, (§80, Theorem 10. If two straight lines intersect each other, the vertical angles are equal.) Draw the lines CE and BD. $\angle DEC=\angle DBC$. (§169, Theorem 57. An angle inscribed in a circle is measured by one-half its intercepted arc.) Thus $\angle DEC$ and $\angle DBC$ are each measured by one-half the arc DC. In the same way $\angle BDE=\angle BCE$. Hence the two triangles AEC and BAD are similar. (§186, Theorem 64. If two triangles have the angles of one respectively equal to the angles of the other, the triangles are similar.) By definition of similar triangles,

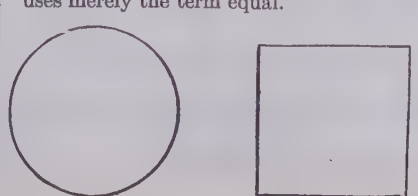
$\frac{AE}{AB}=\frac{AC}{AD}$ or $(AE)(AD)=(AB)(AC)$.

196. Theorem 74.—

If through a point outside a circle a tangent and a secant are drawn, the tangent is the mean proportional between the whole secant and its external segment.



Hint. Show that the triangles ATB and ACT are similar. How is an angle formed by a tangent and a chord measured? See §171. Hence $\frac{AC}{AT}=\frac{AT}{AB}$ or $(AC)(AB)=(AT)^2$.

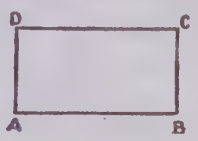


AREAS OF POLYGONS.

We now come to another fundamental concept of geometry, the area of a closed figure.

197. Equal Areas. Equivalence.—Two figures which can be made to coincide are identical and have the same area. But it may be possible in the case of two figures which do not coincide to cut one area up in such a manner that on rearranging its parts it coincides with the second figure. Evidently in this case we must also say that the areas are equal.

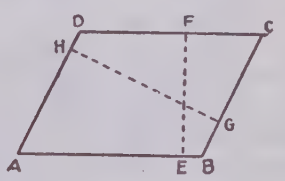
Thus figures I and II, which will not coincide as they stand, can be made to coincide by cutting off the triangle along the dotted line in figure I and moving it to the position indicated in figure II. In these circumstances the areas are called equivalent, symbol $\fallingdotseq$. However one ordinarily uses merely the term equal.



The circle and the square above may have the same area but it is not possible by a finite number of operations to divide the square into pieces so that they will coincide with the circle. We here encounter the same kind of difficulty that occurred in the case of the incommensurable quantities discussed in §177.

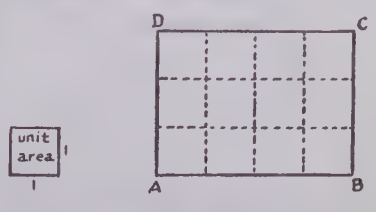
One of the famous problems of geometry is to "square the circle," i.e. to construct a square whose area is equal to the area of a given circle. In the process of cutting up the circle to form a square an infinite number of steps would be required, which can not actually be performed.

198. Unit of Area.—The unit of area which is most convenient is the area of a square whose side is one unit in length. This square is called the unit square. If we are measuring the length of straight lines in feet it is convenient to measure the area in terms of a square of side one foot.



199. Area.—The area of a plane figure is its ratio to the unit square.

200. Base and Altitude of a Rectangle.—



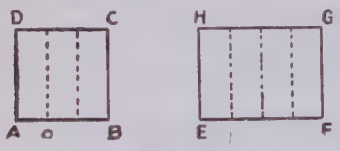
Either one of two adjacent sides of a rectangle can be considered its base. An altitude of a rectangle is a line drawn from any point in one base perpendicular to the other side. If AB is chosen as base, then AD is an altitude. If AD is chosen as base then AB is an altitude. If AB is chosen for the lower base, then DC is the upper base.

201. Base and Altitude of a Parallelogram.—

Either pair of parallel sides can be chosen for the bases, thus if BC is called the lower base then AD is the upper base. The corresponding altitude is the perpendicular distance between the bases. If AB and DC are the bases then EF is the altitude.

202. Area of a Rectangle.—

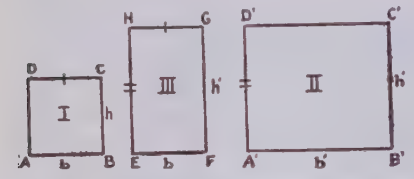
When the lengths of the two sides are commensurable with the side of the unit square there is no difficulty in proving that the area is the product of the base and the altitude. The rectangle above has its base AB, 4 units long, and its altitude



BC, 3 units long. It is evident that it can be cut into $4\times3=12$ squares, each congruent with the unit square. When AB and BC are not commensurable with the side of the unit square we encounter a difficulty which we mentioned before in §197. We pass over the proof of this incommensurable case and assume the truth in all cases of the following theorem:

203. Theorem 75.—

The area of a rectangle is equal to the product of its base and its altitude.



204. Theorem 76.—

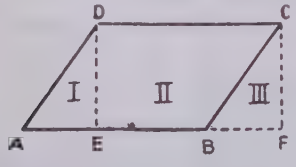
The areas of two rectangles having equal altitudes are to each other as their bases.

Hint. If AB and EF are commensurable so that it is possible to find a length as AO which is contained in both AB and EF an integral number of time, the theorem is evident. $\frac{ABCD}{EFGH}=\frac{AB}{EF}=\frac{3}{4}$

205.—The areas of two rectangles are to each other as the product of their bases and altitudes.

Hyp. Given the rectangles ABCD and $A^1B^1C^1D^1$, with the bases b and b^1, and with the altitudes h and h^1 respectively.

Con. $\frac{ABCD}{A^1B^1C^1D^1}=\frac{bh}{b^1h^1}$.

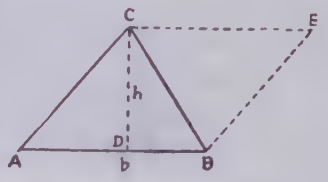


Hint. Construct the rectangle EFGH with the base $EF=b$ and the altitude $FG=h^1$. Rectangles I and III have equal altitudes, b, when BC and FG are considered the bases. Hence by the previous theorem $\frac{I}{III}=\frac{h}{h^1}$. In the same way $\frac{III}{II}=\frac{b}{b^1}$

Take the product of these two equations,

$$\frac{I}{III}\cdot\frac{III}{II}=\frac{I}{II}=\frac{hb}{h^1b^1}.$$

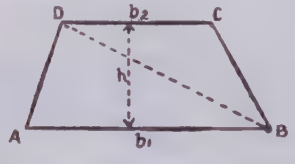
206. Theorem 78.—



The area of a parallelogram is equal to the product of its base and its altitude.

Hint. Drop the perpendiculars from D and C on AB, meeting it in E and F. Show that triangle I is congruent to triangle III. The parallelogram ABCD is composed of I+II. The rectangle EFCD is composed of II+III. Since I=III, I+II=II+III. Hence the parallelogram is equivalent to the rectangle. The area of the rectangle is (DC)(DE). (§203, Theorem 75. The area of a rectangle is equal to the product of its base and its altitude.) Hence the area of the parallelogram is also (DC)(DE) = (base) (altitude); where DC is considered the base of the parallelogram and DE the altitude of the parallelogram.

207. Theorem 79.—

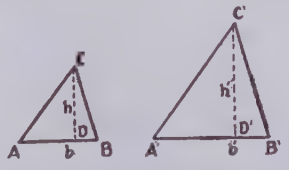


The area of a triangle is equal to half the product of its base and altitude.

Hint. Complete the triangle ABC into the parallelogram ABEC. Show that triangle BEC is congruent to the triangle ABC, hence ABC is one-half the area of the parallelogram. By the previous theorem the area of the parallelogram is bh, hence the area of the triangle is $\frac{1}{2}bh$. AB=b is the base of the triangle and CD=h, the perpendicular distance from C on AB is the altitude.

208. Theorem 80.—

The area of a trapezoid is equal to one-half the product of its altitude and the sum of its bases.

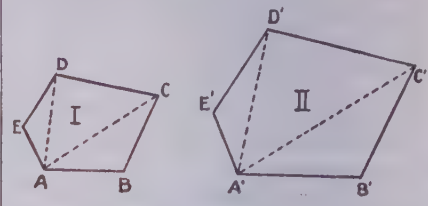


Hint. Draw the diagonal BD dividing the trapezoid ABCD into the two triangles ABD and BDC. $ABD=\frac{1}{2}b_1h$ and $BCD=\frac{1}{2}b_2h$. Therefore

$$ABCD=\frac{1}{2}b_1h+\frac{1}{2}b_2h=\frac{1}{2}(b_1+b_2)h.$$

Definition. The two parallel sides of a trapezoid are called the bases and the altitude is the perpendicular distance between the bases.

209. Theorem 81.—



The areas of two similar triangles are to each other as the squares of any two corresponding sides.

Hint. Show that the triangles ACD and $A^1C^1D^1$ are similar. (§187, Theorem 65. If two triangles have two angles of one respectively equal to two angles of the other, the triangles are similar.) Hence $\frac{h}{h^1}=\frac{AC}{A^1C^1}$ but $\frac{AC}{A^1C^1}=\frac{AB}{A^1B^1}$ therefore $\frac{h}{h^1}=\frac{AB}{A^1B^1}=\frac{b}{b^1}$. Area $ABC=\frac{1}{2}bh$, area $A^1B^1C^1=\frac{1}{2}b^1h^1$. Thus $\frac{ABC}{A^1B^1C^1}=\frac{\frac{1}{2}bh}{\frac{1}{2}b^1h^1}$, replacing $\frac{h}{h^1}$ by its equal $\frac{b}{b^1}$, $\frac{ABC}{A^1B^1C^1}=\frac{b}{b^1}$.

210. Theorem 82.—

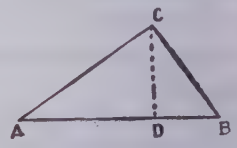
The area of two similar polygons are to each other as the squares of any two corresponding sides; and also as the squares of their perimeters.

Hint. §192, Theorem 70. If two polygons are similar, they can be resolved into the same number of triangles, similar each to each and similarly placed. Resolve ABCDE into triangles ABC, ACD, and ADE, which are similar to the triangles $A^1B^1C^1$, $A^1C^1D^1$, and $A^1D^1E^1$, respectively, into which $A^1B^1C^1D^1E^1$ is resolved.

Then $\frac{ABC}{A^1B^1C^1}=\frac{(AB)^2}{(A^1B^1)^2}$, $\frac{ACD}{A^1C^1D^1}=\frac{(CD)^2}{(C^1D^1)^2}$, and $\frac{ADE}{A^1D^1E^1}=\frac{(DE)^2}{(D^1E^1)^2}$ (§209, Theorem 81. The areas of two similar triangles are to each other as the squares of any two corresponding sides.)

From the definition of similar polygons we have $\frac{AB}{A^1B^1}=\frac{CD}{C^1D^1}=\frac{DE}{D^1E^1}$. Therefore $\frac{(AB)^2}{(A^1B^1)^2}=\frac{(CD)^2}{(C^1D^1)^2}=\frac{(DE)^2}{(D^1E^1)^2}$. (§43, Axiom. Like powers of equals are equal.) Hence $\frac{ABC}{A^1B^1C^1}=\frac{ACD}{A^1C^1D^1}=\frac{ADE}{A^1D^1E^1}=\frac{(AB)^2}{(A^1B^1)^2}$ Applying the properties of a proportion §180, III to this expression gives

$$\frac{ABC+ACD+ADE}{A^1B^1C^1+A^1C^1D^1+A^1D^1E^1}=\frac{(AB)^2}{(A^1B^1)^2},\text{ or}$$



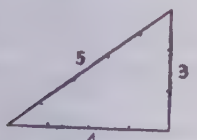
$$\frac{ABCDE}{A^1B^1C^1D^1E^1}=\frac{(AB)^2}{(A^1B^1)^2}.$$

The second part of the theorem follows from §193, Theorem 71. The perimeters of two similar polygons are in the same ratio as any two corresponding sides. Hence $\frac{\text{Perimeter of I}}{\text{Perimeter of II}}=\frac{AB}{A^1B^1}$, thus $\frac{(\text{Perimeter of I})^2}{(\text{Perimeter of II})^2}=\frac{(AB)^2}{(A^1B^1)^2}$. Therefore

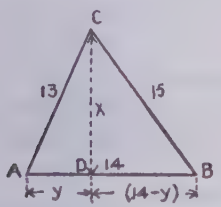
$$\frac{ABCDE}{A^1B^1C^1D^1E^1}=\frac{(\text{Perimeter of I})^2}{(\text{Perimeter of II})^2}.$$

211. Theorem 83.—

The square of the hypotenuse of a right triangle is equal to the sum of the squares of the other two sides.



Hyp. Given the triangle ABC with a right angle at C.



Con. $(AB)^2=(AC)^2+(BC)^2$.

Hint. Draw the perpendicular from C on AB, meeting it in D. Then $(AC)^2=(AB)(AD)$ and $(BC)^2=(AB)(DB)$. (§194, Theorem 72. Each leg of a right triangle is the mean proportional between the hypotenuse and the segment adjacent to

that leg.) Adding these two equalities, $(AC)^2+(BC)^2=(AB)(AD)+(AB)(DB)$ · $AB(AD+DB)=(AB)(AB)=(AB)^2$. This theorem is one of the most important of the theorems of plane geometry and is called the theorem of Pythagoras, a very celebrated Greek geometer (580-500 B. C.). The 3, 4, 5 right triangle was known to the Egyptians, who used a rope 12 units long with knots in it at the proper points to stake out a triangle whose sides should be 3, 4, and 5 units respectively, thus giving them a right angle opposite the side of 5 units.

212. Area of Any Triangle When the Three Sides are Given.—As an application of the theorem of Pythagoras we will find the area of a triangle whose three sides are 13, 14, and 15 inches.

Let ABC be the triangle with the given sides so that AB=14, BC=15, and CA=13. Drop the perpendicular from C on AB, meeting it in D. Let CD=x, and AD=y, then DB=14—y. Applying the theorem of Pythagoras to the two right triangles ADC and CDB gives

(1) $x^2+y^2=(13)^2$,
(2) $x^2+(14-y)^2=(15)^2$.

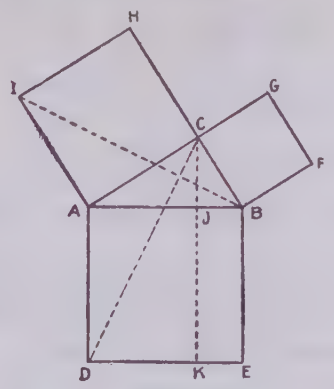
Square out (2) gives (3) $x^2+196-28y+y^2=225$.

Subtract (1) from (3) gives (4) $196-28y=56$,
or (5) $28y=140$,
or (6) $y=5$.

Substituting $y=5$ in (1) gives (7) $x^2+(5)^2=(13)^2$,
or (8) $x^2=144$,
or (9) $x=12$.

The area equals one half the base times the altitude $=\frac{1}{2}(14)(12)=84$ square inches. §207, Theorem 79.

By the same method a general formula can be obtained for the area of a triangle of sides a, b, c. The area is $\sqrt{s(s-a)(s-b)(s-c)}$, where $s=\frac{1}{2}(a+b+c)$. We will apply this formula to the example above.



$a=15$
$b=13$
$c=14$

$2s=a+b+c=42$.
$\therefore s=21$.
$s-a=6$,
$s-b=8$,
$s-c=7$,

$\triangle=\sqrt{s(s-a)(s-b)(s-c)}=\sqrt{(21)(6)(8)(7)}=\sqrt{7056}=84$ square inches.

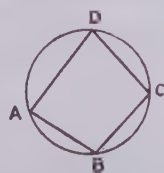
213.—The theorem of Pythagoras has a score of proofs. Its importance justifies the outline of a second proof. We will also change the wording

The square on the hypotenuse of a right triangle is equivalent to the sum of the squares on the other two sides.

Hyp. Given the triangle ABC with C a right angle. On AB erect the square DEBA, on BC the square FGCB, on AC the square HIAC.

Con. DEBA=FGCB+HIAC.

Draw CJ perpendicular to AB through C, meeting AB in J and DE in K. Draw CD and IB. Prove $\triangle IAB=\triangle CAD$, hence $2(\triangle IAB)=2(\triangle CAD)$. But $2(\triangle IAB)=$ HIAC and $2(\triangle CAD)=$ ADKJ. Hence square HIAC equals rectangle ADKJ. By drawing AF and CE, in just the same way, square FGCB=rectangle JKEB. Adding these equalities, square FGCB+square HIAC=rectangle ADKJ+rectangle JKEB =square ADEB.



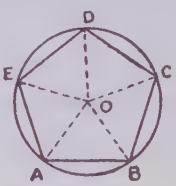
REGULAR POLYGONS AND THE MEASURE OF THE CIRCLE

214.—Equilateral Polygon.—A polygon all of whose sides are equal is an equilateral polygon.

215. Equiangular Polygon.—A polygon all of whose interior angles are equal is an equiangular polygon.

216. Regular Polygon.—A regular polygon is a polygon all of whose angles and all of whose sides are equal. It is both equilateral and equiangular.

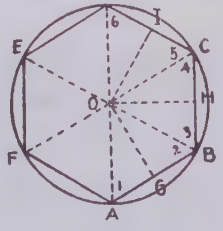
217. Inscribed Polygon.—A polygon is inscribed in a circle when all its vertices lie on the circumference, as ABCD. The circle is said to circumscribe the polygon.



218. Circumscribed Polygon.—A polygon is circumscribed about a circle when all its sides are tangent to the circle, as EFGH. The circle is said to be inscribed in the polygon.

219. Apothem.—The apothem of a regular polygon is the perpendicular from the center of its circumscribed or inscribed circle to any side of the polygon.

220. Theorem 84.—
An equilateral polygon inscribed in a circle is a regular polygon.



Hyp. The sides of the polygon ABCDE inscribed in the circle are equal, AB=BC=CD=DE=EA.

Con. The polygon is a regular polygon.

Hint. A regular polygon has all of its sides and all of its angles equal, §216. Since the sides are equal by hypothesis it remains to prove that the angles are equal. Angle A is measured by ½ arc BCDE, which is 3/5 of a circumference. (§169, Theorem 57. An angle inscribed in a circle is measured by one-half of its intercepted arc.) In the same way angle B is measured by ½ of the arc AEDC, which is 3/5 of a circumference. Hence $\angle A=\angle B=\angle C=\angle D=\angle E$.

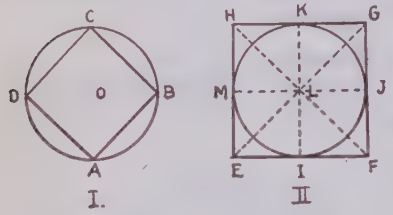
A second method of proof is to draw the radii OA, OB, OC, OD, OE, and show that all the triangles OAB, ODC, OCD,. . . . , are congruent.

221. Theorem 85.—
A circle may be circumscribed about any regular polygon, and a circle may also be inscribed in it.

Hyp. Given the regular polygon ABCDEF.

Con. A circle may be circumscribed about ABCDEF, and a circle may be inscribed in ABCDEF.

Hint. Draw the circle through the three points A, B, and C. Let the center of this circle be O. (§147, Theorem 39. Through three points not lying in a straight line one circle, and only one, can be drawn.) Draw the radii OA, OB, OC and the line OD, which we do not know to be a radius of the circle, through A, B, C until we prove that it is. Consider the triangles OAB and OCD, OB=OC, AB=CD, $\angle 2+\angle 3=\angle 4+\angle 5$ but $\angle 3=\angle 4$, subtraction of equals from equals gives $\angle 2=\angle 5$. Hence the triangles OAB and OCD are congruent. (§64, Theorem 1. If two triangles have two sides and the included angle of one equal to two sides and the included angle of the other, the triangles are congruent.) Hence OA=OD, being corresponding sides of congruent triangles. Therefore OD is a radius of the circle.



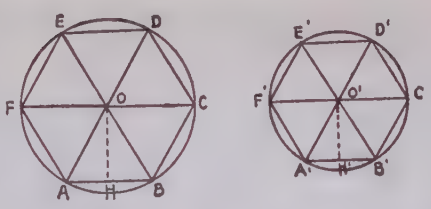
To prove that a circle can be inscribed. Draw all the perpendiculars from O to the sides of the polygon, as OG, OH, OI, ... and prove these all equal. Then a circle with O as center and OG for radius will pass through G, H, I...and this circle will be tangent to the sides AB, BC, CD,... (§161, Theorem 53. A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact.) Hence the centers of the inscribed and circumscribed circle coincide.

222. Center of a Regular Polygon.—The center of a regular polygon is the common center of its circumscribed and inscribed circles, as the point O of §221.

223. Radius of a Regular Polygon.—The radius of a regular polygon is the radius of the circumscribing circle, as OA of §221.

224. Angle at the Center of a Regular Polygon.—The angle at the center of a regular polygon is the angle subtended by a side of the polygon considered as a chord of its circumscribed circle, as angle AOB of §221.

225. Theorem 86.—
If a circle be divided into any number of equal parts, the chords joining the successive points of division form a regular polygon inscribed in the circle; and the tangents drawn at the points of division form a regular polygon circumscribed about the circle



I. II.

See figure I. Hint. The sides AB, CB,... are equal, for the arcs AB, CB,... are equal by hypothesis. (§150, Theorem 42.) The angles A, B,..., are equal, for they are measured by equal arcs. (§169, Theorem 57.) See figure II. Hint. Triangles LJF and LIF are congruent. (§87, Theorem 15.) Hence IF = FJ = JG = ..., therefore the sides are equal, or FG = GH = HE .... Also ∠IFL = ∠LFJ = ∠LGJ = ..., hence the angles are equal, or ∠F = ∠G = = ∠H = ...

226. Theorem 87.—
Regular polygons of the same number of sides are similar.

Hint. We must prove their angles are equal and their sides are in proportion. They can be inscribed in circles. (§221, Theorem 85.) Their angles are equal, for they are measured by one half of the same fractional part of a circumference. Since all the sides of each polygon are equal, the ratio of a side of the first to a side of the second is constant, hence the corresponding sides are in proportion.

227. Theorem 88.—
The perimeters of regular polygons of the same number of sides are to each other as the radii of the circumscribed circles, or as the radii of the inscribed circles; and their areas are to each other as the squares of the radii.

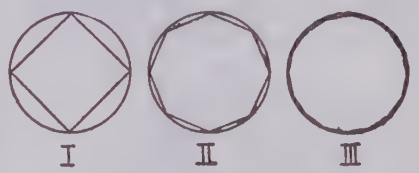
Hint. $\frac{AB + BC + CD + DE + EF,}{A^1B^1 + B^1C^1 + C^1D^1 + D^1E^1 + E^1F^1} = \frac{6(AB)}{6(A^1B^1)} = \frac{AB}{A^1B^1} = \frac{OB}{O^1B^1}$, since triangles OAB and $O^1A^1B^1$ are similar. Also let OH and O^1H^1 be the perpendiculars upon AB and A^1B^1 from the centers O and O^1 respectively, then the triangles OHB and $O^1H^1B^1$ are similar and $\frac{OB}{O^1B^1} = \frac{OH}{O^1H^1}$. Thus

$$\frac{\text{perimeter of ABCDEF}}{\text{perimeter of } A^1B^1C^1D^1E^1F^1} = \frac{OB}{O^1B^1} = \frac{OH.}{O^1H^1}$$

$$\frac{\text{Area of ABCDEF}}{\text{Area of } A^1B^1C^1D^1E^1F^1} = \frac{(AB)^2}{(A^1B^1)^2} =$$

$$\frac{(\text{perimeter of ABCDEF})^2}{(\text{perimeter of } A^1B^1C^1D^1E^1F^1)^2}.$$

(§210, Theorem 82.) Since $\frac{AB}{A^1B^1} = \frac{OB}{O^1B^1} = \frac{OH}{O^1H^1}$, then $\frac{(AB)^2}{(A^1B^1)^2} = \frac{(OB)^2}{(O^1B^1)^2} = \frac{(OH)^2}{(O^1H^1)^2}$.



(§43, Axiom.) Therefore

$$\frac{\text{area of ABCDEF}}{\text{area of } A^1B^1C^1D^1E^1F^1} = \frac{(OB)^2}{(O^1B^1)^2} = \frac{(OH)^2}{(O^1H^1)^2}.$$

228. Theorem 89.—
The area of a regular polygon is equal to one-half the product of its perimeter and its apothem.

Hint. Use the figure of the previous theorem, area ABCDEF = 6(area ABO) = 6(½) (AB) (OH) = ½(6AB) (OH) = ½(perimeter of ABCDEF) (apothem). (§219. Definition).

229. Relation of the Regular Polygons to the Circle.—While the theorems on regular polygons have in themselves interest and use, they have been developed chiefly in order that they may be applied to the circle. We must look upon the circle as a regular polygon of an infinite number of sides.

I II III

Take a series of equal circles. In the first circle inscribe a regular polygon of 4 sides (a square), in the second inscribe a regular polygon of 8 sides, in the third inscribe a regular polygon of 16 sides, in the fourth inscribe a regular polygon of 32 sides.
As this process continues each time the area of the polygon more nearly approaches the area of the circle, the perimeter of the polygon more nearly approaches the circumference of the circle, and the apothem of the polygon more nearly approaches the radius of the circle. If we were able to continue this process an infinite number of times the polygon would coincide with the circle. We shall now restate our theorems for the regular polygons in such a manner that they apply to the circle.

230. Theorem 90.

The circumferences of two circles are to each other as the radii.

This follows from §227, replacing perimeter by circumference.

231. Theorem 91.—

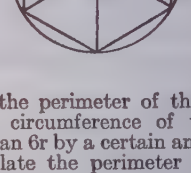
The ratio of the circumference of any circle to its diameter is a constant.

Hint. Given two circles with the radii r and r_1, with the corresponding diameters d and d_1, and with the circumferences C and C_1, then $\frac{C}{C_1} = \frac{r}{r_1} = \frac{2r}{2r_1} = \frac{d.}{d_1}$. (§230, theorem 90.) Since $\frac{C}{C_1} = \frac{d}{d_1}$, $\frac{C}{d} = \frac{C^2.}{d^2}$ (§180, I).

Since $\frac{C}{d}$ or the ratio of the circumference to the diameter is the same for any two circles it must be a constant. This constant is always designated by π. Hence $\frac{C}{d} = \pi$ or $C = \pi d$.

232. Theorem 92.—

The areas of two circles are to each other as the squares of the radii.

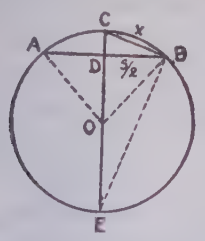


Hint. This follows from §227.

233. Theorem 93.—

The area of a circle is equal to half of the product of its circumference and its radius; or the product of the square of the radius and the constant number π.

Hint. From §228, Theorem 89, the area of a regular polygon = ½ (perimeter) (apothem), considering the circle as a regular polygon of an infinite number of sides, we must replace perimeter by circumference and apothem by radius. Therefore S = area of a circle = ½Cr = ½(2πr)(r) = πr², replacing C by its value 2πr from §231.



234. Computation of π. In §257 we will show that a regular hexagon can be inscribed in a circle and that its side is equal to the radius of the circumscribing circle.

Hence the perimeter of the hexagon is 6r. The circumference of the circle is greater than 6r by a certain amount. If we can calculate the perimeter of a regular polygon of 12 sides this will give us a value nearer to the circumference of the circle. (§229). Instead of calculating the side of a regular polygon of 12 sides in terms of r we will solve the more general problem below.

If s is the side of a regular inscribed polygon, x the side of a regular inscribed polygon having twice as many sides as the first, and r the radius of the circumscribing circle of both, find x in terms of s and r.

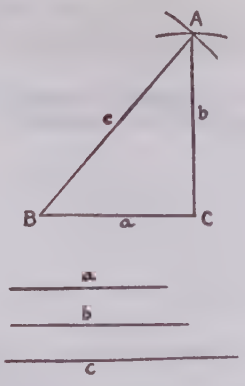
Hyp. Given a circle, center O and radius r. Let s = AB be the side of a regular inscribed polygon and x = CB be the side of a regular inscribed polygon of double the number of sides.

Required. To find the value of x in terms of s and r.

Hint. Draw the diameter CE, and the lines OB and BE. Since chord AC = chord CB, CO is perpendicular to AB and meets it in a point D. Triangle CBE is a right triangle, and $(CB)^2 = x^2 = (CD)(CE)$. (§194, Theorem 72c.) Hence $x = \sqrt{(CD)(CE)} = \sqrt{(CD)(2r)}$. But CD = CO—DO = r—DO and $DO = \sqrt{(OB)^2 - (DB)^2} = \sqrt{r^2 - \frac{(s)^2}{(2)}}$. (§211, Theorem 83.) Hence $CD = r - \sqrt{r^2 - \frac{(s)^2}{(2)}}$, replacing CD by this value in $x = \sqrt{2r(CD)}$ we have the formula desired

$$x = \sqrt{2r^2 - 2r\sqrt{r^2 - \frac{(s)^2}{(2)}}}.$$

If we now put s = r in this equation we will find the length of the side of a regular polygon of 12 sides.



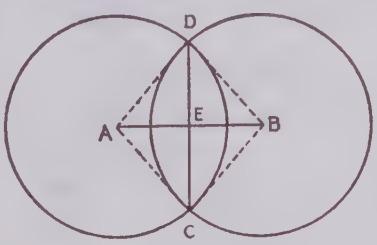
$$x = \sqrt{2r^2 - 2r\sqrt{r^2 - \frac{r^2}{4}}} = r\sqrt{2 - \sqrt{3}}.$$

Multiply this by 12 gives the perimeter of a regular polygon of 12 sides, the value is 6.211657r. It is possible to continue the calculations for regular polygons of, 24, 48, 96,... sides. When the value is calculated for a regular polygon of 1,536 sides, the perimeter of the polygon is 6.28318r, dividing by 2r gives the value of $\pi = 3.14159$, correct to 5 decimal places. In advanced mathematics other and easier methods have been developed for the calculation of this most important constant.

PROBLEMS OF CONSTRUCTION.

235. Constructions by ruler and compasses.—Because I can define an object does not prove that it exists. We define a secant line as a line which cuts a circle in two points. I might define a hypersecant as a straight line which cuts a circle in three points, but it is impossible to draw such a line; in fact it is possible to prove it does not exist. Having defined a geometrical object, the mathematician proceeds, if possible, to prove that it exists. For instance in §69 we made use of the bisector of an angle; we did not at that time tell how to obtain the bisector, we merely assumed that it was possible to obtain it in some as yet unknown manner. Again and again we have drawn lines which we assumed were perpendicular to each other. We will now proceed to show how to carry out these constructions with the use of the ruler and compasses. Note. The constructions are not always given in full, it being assumed that the methods of a previous construction need not be indicated in full in a drawing.

236. To construct a triangle, when the three sides are given.—

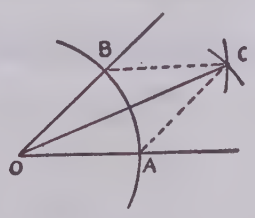


Given the three sides of a triangle a, b, and c.

Required to construct the triangle with these segments for sides.

By use of the compasses mark off BC equal to a. With B as center draw a circle of radius c, with C as center draw a circle of radius b, let these two circles intersect in A. Triangle ABC is the required triangle.

237. To bisect a given line.—

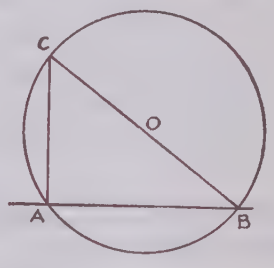


Given the line AB.

Required to construct the midpoint of AB.

Choosing a convenient radius, draw two circles with A and B as centers. Let these two circles intersect in C and D and let CD intersect AB in E. The required midpoint of AB is E. (§91. Theorem 17. The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.) Since AD = BD = AC = BC, C and D are two points equidistant from both A and B, thus they determine the perpendicular bisector.

238. To bisect a given angle.—

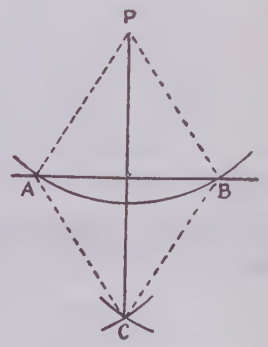


Given the angle AOB.

Required to construct the line bisecting the given angle.

Choosing a convenient radius, draw a circle intersecting the sides of the angle in A and B. Draw two circles with A and B as centers, both circles having the same radius, and let C be the point of intersection of these circles. Draw OC. Consider the triangles OAC and OBC, OA = OB—radii of the same circle; AC = BC—radii of two equal circles; OC is common. Therefore the triangles are congruent. (§77. Theorem 9. If two triangles have the three sides of one respectively equal to the three sides of the other, the triangles are congruent.) Angles AOC and BOC are equal, and AC is the bisector required.

239. At a given point in a straight line to erect a perpendicular to the line.—

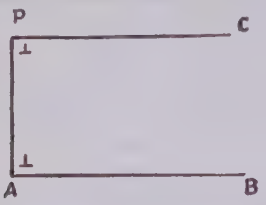


Given a line AB and a point A on it.

Required to construct the line through the point A perpendicular to the given line.

Choose a convenient point as O, and with a radius OA draw a circle cutting AB in A and a second point B. Draw the diameter of the circle BC and the line AC. Angle BAC is measured by one-half of a semicircle, and thus is a right angle. (§170, Theorem 58. An angle inscribed in a semicircle is a right angle.) Therefore AC is the required line.

240. From a given point to let fall a perpendicular upon a given line.—

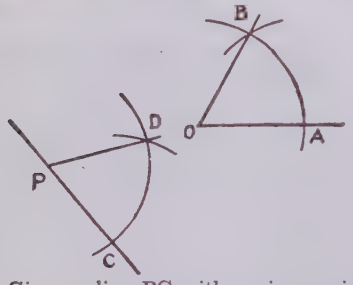


Given a line AB and a point P outside the line.

Required to construct the line through P perpendicular to AB.

Draw a circle with P as center cutting the given line in any two points as A and B. Draw two circles with A and B as centers and having the same radius. Let these two circles intersect in C. Then AP = PB—radii of the same circle; CA = CB—radii of equal circles. Therefore P and C are each equidistant from A and B. Hence PC is the required perpendicular. (§89, Theorem 16. The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.)

241. Through a given point to draw a parallel to a given line.—

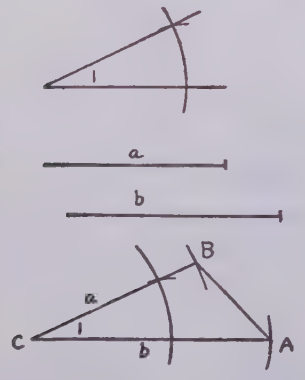


Given a line AB and a point P outside the line.

Required to construct the line through the point P parallel to the line.

From P draw the perpendicular to the line AB; let this line be PA. At P draw the perpendicular PC to the line PA. Then PC is the required parallel to AB. (§93, Theorem 18. Two straight lines perpendicular to the same straight line are parallel.)

242. Through a given point on a straight line, to draw a line making a given angle with the given line.—

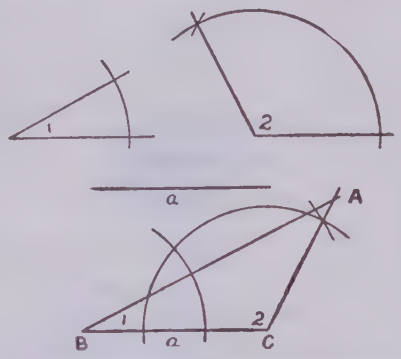


Given a line PC with a given point P upon it, let angle AOB be the given angle.

Required to draw the line through P forming with PC an angle equal to the given angle.

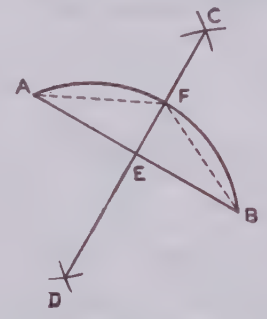
Draw a circle with O for center, cutting the sides of the given angle in the points A and B. With the same radius draw a circle with P for center. Draw a circle with C for center having AB for radius; let D be the point of intersection of the two arcs having P and C for centers. Angle CPD is the required angle. (§149, Theorem 41. If in the same circle, or in equal circles—two arcs are equal, the angles which they subtend are equal.)

243. To construct a triangle, when two sides and the included angle are given.—



Given the angle 1 and the segments a and b.

Required to construct the triangle, which has a and b for two sides, including the given angle 1.

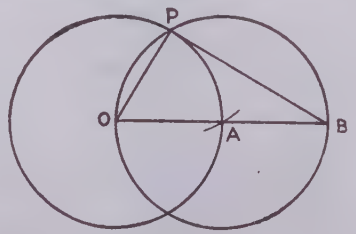


By the method of §242 construct the angle ACB equal to the given angle 1. Mark off CB equal to the segment a, and CA equal to the segment b. Draw AB. ABC is the required triangle.

244. To construct a triangle when two angles and the included side are given.—

The method is the same as the previous construction.

245. To bisect a given circular arc.—

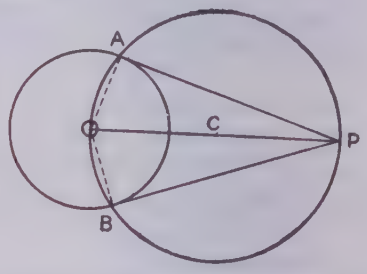


Given the circular arc AB.

Required to construct the mid-point of the arc.

Draw the chord AB and its perpendicular bisector CD. Let the line CD meet the chord AB in E and the arc AB in F. Draw AF and FB. Chord AF = Chord FB. (§89. Theorem 16, The locus of points equidistant from two given points is the perpendicular bisector of the line joining them.) Therefore arc AF = arc FB and F is the required mid-point. (§151, Theorem 43. If in the same circle, or in equal circles, two chords are equal, the arcs subtended by them are equal.)

246. At a given point on a given circle, to draw a tangent to the circle.—

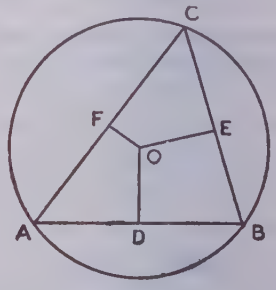


Given a circle of radius r with the center O and the fixed point P on it.

Required to construct the tangent to the given circle at the point P.

One method is to draw the radius OP and construct the line perpendicular to OP at the point P by method of §239. A second method is as follows. With P as center and with a radius equal to r, draw an arc cutting the given circle in A. With A for center draw a circle of radius r. This circle will pass through O and P. Draw OAB the diameter of the circle with the center A, and then draw the chord PB. Angle OPB is a right angle. (§170. Theorem 58. An angle inscribed in a semicircle is a right angle.) Therefore PB is the required tangent. (§161, Theorem 53. A straight line tangent to a circle is perpendicular to the radius drawn to the point of contact.) (18. Axiom. From a given point in a given line, one perpendicular and only one, can be drawn to the line.)

247. Through a given point outside a given circle to draw tangents to the circle.—

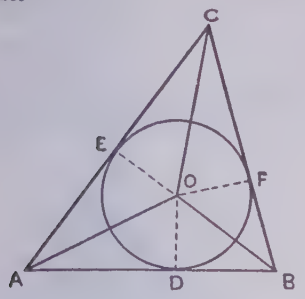


Given the circle with its center at O and the point P outside the circle.

Required to construct the tangents from P to the circle.

Draw the line OP, find the mid-point of this line C, and draw the circle with the center C and the radius OC. Let this circle intersect the given circle in the two points A and B. Draw the lines, OA, OB, AP, and BP. Angles OAP and OBP are right angles. (§170, Theorem 58. An angle inscribed in a semicircle is a right angle.) Therefore AP and BP are the required tangents. As in the previous construction, the tangent is perpendicular to the radius at its extremity.

248. To circumscribe a circle about a given triangle.—



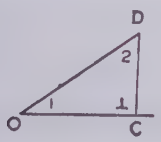
Given the triangle ABC.

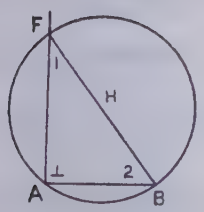
Required to circumscribe a circle about ABC.

Draw the perpendicular bisectors of the sides AB and BC, let O be their point of intersection. Designate the perpendicular bisector of AB by DO and the perpendicular bisector of BC by EO. Point O, lying in OD, is equidistant from A and B, lying in OE; it is also equidistant from B and C or OA = OB = OC. Hence the perpendicular bisector of AC also passes through FO. (§89. Theorem 16. The locus of points

equidistant from two given points is the perpendicular bisector of the line joining them.) Since O is equidistant from A, B, and C it is the center of the required circle.

249. To inscribe a circle in a given triangle.—



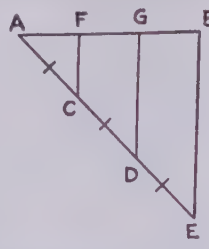


Given the triangle ABC.

Required to inscribe a circle in the triangle ABC.

Let the bisectors of the angles A and B meet in the point O. Then OA and OB are the bisectors of the angles A and B respectively. Draw the perpendiculars from O to AB, BC, and CA, let these be OD, OF, and OE respectively. Every point in AO is equidistant from AC and AB, hence OE=OD. Every point in OB is equidistant from BA and BC, hence OD=OF. We might observe that the bisector of angle C must also pass through the point O. (§91, Theorem 17. The locus of points equidistant from the sides of an angle is the bisector of the angle.) Therefore O is the center of the required circle and the radius =OD=OF=OE.

250. On a given straight line as a base, to construct a circular segment in which a given angle can be inscribed.—

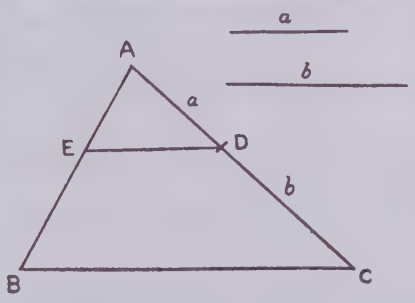


Given the angle COD and the straight line AB.

Required to construct the circular segment in which the given angle can be inscribed.

Take any point D on the side OD of the given angle and drop the perpendicular upon the side OC, meeting it in C. At the point A draw the perpendicular AF to AB; at the point B construct the angle ABF equal to the angle ODC. The triangles ABF and OCD are similar, and angle AFB equals the given angle COD. (§ 187, Theorem, 65. If two triangles have two angles of one respectively equal to two angles of the other, the triangles are similar.) Therefore the circular segment AFB is the segment required, for any angle APB with its vertex P on this segment has the same measure, i. e., one half of the arc AB, as the angle AFB. (§169, Theorem 57. An angle inscribed in a circle is measured by one half its intercepted arc.

251. To divide a given straight line into any number of equal parts.—



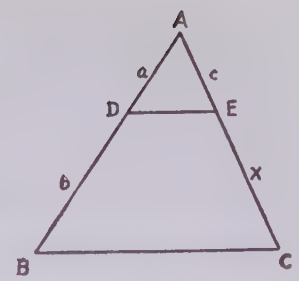
Given the straight line AB.

Required to divide AB into a certain number of equal parts, say three.

Upon any line through A, as AF, lay off by repeated use of the compasses the equal line segments, AC, CD, and DE. Draw the line BE, and the lines through C and D parallel to EB, meeting AB in the points F and G respectively. F and G are the required points to trisection. (§117, Theorem 37. If a series of parallel lines cut off equal segments on one transversal, they cut off equal segments on any other transversal.)

252. To divide a given straight line into parts proportional to two given lines.—

Given the straight line AB and two other given lines a and b.



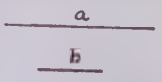
Required to divide the line AB in the ratio of a to b, or to find the point E on AB so that $\frac{AE}{EB} = \frac{a}{b}$

Draw a line through A and on it mark off AD, equal to a, and DC, equal to b.

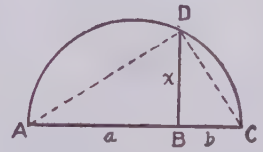
Draw BC and ED parallel to BC through the point D, meeting AB in E. The required point of division is E. (§181, Theorem 62. A straight line parallel to the base of a triangle divides the other two sides proportionally.)

253. Fourth proportional.—A fourth proportional to three numbers or magnitudes a, b, and c, is the quantity x defined by $\frac{a}{b} = \frac{c}{x}$.

254. To find the fourth proportional to three given lines.—



Given the three lines a, b, and c.

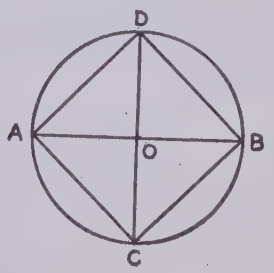


Required to construct the line which is the fourth proportional.

Draw two lines intersecting in a point A. On one of these lines lay off AD equal to a and DB equal to b, on the second line lay off AE equal to c. Draw the line DE and draw a line through B parallel to DE, meeting AE in C. Then EC=x is the fourth proportional required for $\frac{a}{b} = \frac{c}{x}$.

(§181, Theorem 62. A straight line parallel to the base of a triangle divides the other sides proportionally.)

255. To find the mean proportional between two given straight lines.—

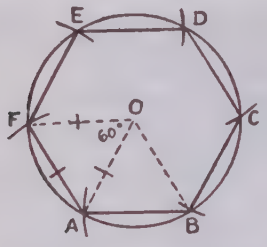


Given the two lines a and b.

Required to construct the mean proportional x between the lines a and b which is defined by the equation $x^2 = ab$.

Draw a straight line through any point A. On this line measure off AB equal to a and BC equal to b. On AC as diameter draw a semicircle. Let the perpendicular to AB at B meet the semicircle in D. BD is the required mean proportional. (194, Theorem 72. The perpendicular is the mean proportional between the segments of the hypotenuse.)

256. To inscribe a square in a given circle.—

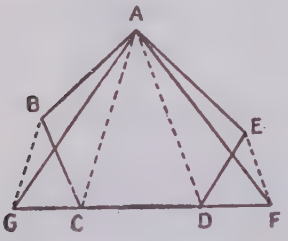


Give the circle O.

Required to inscribe a square in the given circle.

Draw any diameter as AB and draw the diameter CD, which is perpendicular to AB at O the center. Draw AC, CB, BD, DA, which are the sides of the required square. (§148, Theorem 40. If in the same circle, or in equal circles, two angles at the center are equal, the arcs which they intersect are equal.) (§150, Theorem 42. If in the same circle, or in equal circles, two arcs are equal, the chords subtending them are equal.)

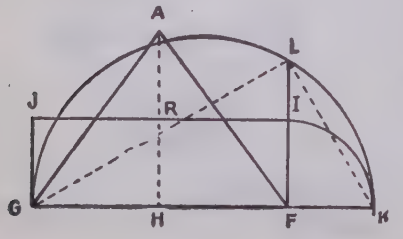
257. To inscribe a regular hexagon in a circle.—



Given a circle.

Required to construct a regular hexagon.

Using any point of the given circle as A for center and with a radius equal to the radius of the given circle draw an arc cutting the circle in F. Draw from O, the center of the given circle, the radii OA and OF. Triangle AOF has all its sides equal, hence all of its angles are equal. Thus angle AOF is one-third of two right angles, or one-sixth of a circumference. Hence AF is the side of the required hexagon.



258. To transform any convex polygon into a triangle; a square.—

Given the convex polygon ABCDE.

Required to transform ABCDE (a) into a triangle, (b) into a square.

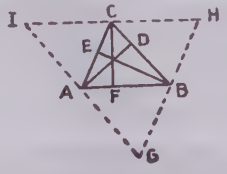
(a) Choose a vertex as A and draw the lines AC and AD. Prolong a convenient side as CD in both directions. Through B draw a line parallel to AC, to meet CD in G, and through E draw a line parallel to AD, meeting CD in F. Triangles ACB and AGC have a common base AC and equal altitudes, since parallel lines are everywhere equidistant. (§207, Theorem 79. The area of a triangle is equal to half of the product of its base and altitude.) In the same way triangles ADE and AFD are equal. Hence triangle AGF is the required triangle.

(b) Having transformed the polygon into a triangle, we will now transform it first into a rectangle and finally into a square.

Let AGF be the given triangle. Draw the perpendicular from A on GF, meeting it in H. Bisect AH. and let R be the point of bisection. Construct a rectangle which has GF for base and HR for altitude. Let GFIJ be this rectangle. The area of the rectangle equals the area of the triangle. The area of the rectangle is equal to the product (GF) (FI). If x is the side of a square of equal area then $x^2 = (GF)(FI)$. The construction of x leads back to §269. (To construct the mean proportional between two given straight lines.) Following the method of that section, we lay off FK on GF equal to FI, draw the semicircle on FK as diameter, and prolong FI until it intersects the semicircle in the point L. FL is the side of the required square whose area is equal to the area of the rectangle GFIJ, to the area of the triangle AGF, and to the area of the polygon ABCDE.

Note. If the polygon were not convex it would be necessary in the first part of the construction (a) to subtract the areas of certain of the triangles instead of adding them.

PROPOSITIONS AND EXERCISES



If when three coins are tossed they always all come heads, we know at once that the matter demands investigation. In a like manner in geometry, if three points are always on a straight line, we seek the reason. Again, if three lines are drawn at random in a plane there is small chance that they pass through a point, in general they will form a triangle.

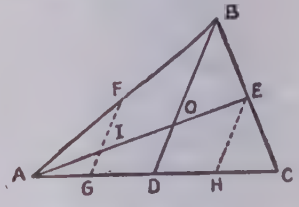
259. Concurrent Lines.—Three or more lines meeting in a common point are called concurrent lines.

We will now consider a few important cases of concurrent lines.

260. Theorem.—The perpendicular bisectors of the sides of a triangle meet in a point equidistant from the three vertices. This point is called the center of the circumscribing circle and the method of proof is given in the construction problem of §248.

261. Theorem.—The perpendiculars from the vertices of a triangle to the opposite sides meet in a point.

Hyp. Given the triangle ABC, with the perpendiculars AD, BE, and CF drawn through the vertices to the opposite sides.



Con. The lines AD, BE, and CF are concurrent.

Hint. Through each vertex of the triangle draw a line parallel to the opposite sides and let these lines intersect to form the triangle GHI. For this triangle the lines AD, BE, CF are the perpendicular bisectors, hence the proof depends upon §260.

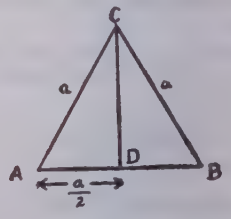
262. Theorem.—The bisectors of the angles of a triangle meet in a point equidistant from the three sides. This point is the center of the inscribed circle, and the method of proof is indicated in §249.

263. Median.—A median of a triangle is a line connecting a vertex to the midpoint of the opposite side.

264. Theorem.—The medians of a triangle meet in a point two-thirds of the distance from each vertex to the midpoint of the opposite side.

Hyp. Given the triangle ABC, with D, E, and F, the midpoints of the sides AC, CB, and BA respectively.

Con. The medians AE, BD, and CF are concurrent.



Hint. We will draw only two medians at first, AE and BD intersecting in O. We will show that AO = 2(OE) and BO = 2(OD). Draw FG and EH through F and E respectively parallel to BD to meet AC at G and H. Let FG and AE intersect in I. Then AG = GD = DH = HC. (§117, Theorem 37.) By the same theorem $AI = IO = OE$. Hence $AO = \frac{2}{3}(AE)$. In the same manner we can prove that AE and CF will intersect in a point O^1 such that $AO^1 = \frac{2}{3}(AE)$. Hence $AO = AO^1$, thus O and O^1 coincide, therefore all the medians pass through O.

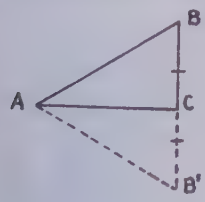
265. Equilateral Triangle.—A triangle is equilateral when all its sides are equal.

266. Equiangular Triangle.—A triangle is equiangular when all its angles are equal.

267. Scalene Triangle. — A triangle is scalene when no two sides are equal.

268. Exercise.—Find the altitude and area of an equilaterial triangle of side a.

Given the equilateral triangle ABC with the side a.



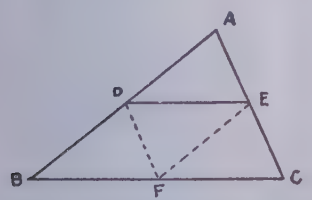
Required to find the altitude CD and the area of the triangle.

The point D is the midpoint of the base, hence AD = a/2. ADC is a right triangle, hence, $a^2 = \left(\frac{a}{2}\right)^2 + (CD)^2$, or $4(CD) = 3a^2$.

(§211, Theorem 83.) Hence $CD=\frac{a\sqrt{3}}{2}$.

The area $=\left(\frac{1}{2}\right)(a)\left(\frac{a\sqrt{3}}{2}\right)=\frac{a^2\sqrt{3}}{2}$. (§207, Theorem 79).

269. Theorem.—If one acute angle of a right triangle is double the other, the hypotenuse is double the shorter side.

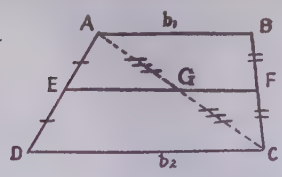


Hyp. Given the right triangle ABC with $\angle C$ the right angle and $\angle B=2\angle A$.

Con. AB is double BC.

Hint. Prolong BC through C to B^1 making CB^1 equal to BC. Draw AB^1. Triangles ABC and AB^1C are congruent. $\angle BAC+\angle B^1AC=\angle B=\angle B^1$, hence the triangle is equiangular and equilateral. Thus $AB=BB^1$, therefore $AB=2BC$.

270. Theorem.—The line which bisects two sides of a triangle is parallel to the third side and is equal to one-half of the third side.



Hyp. D and E are the midpoints of the sides AB and AC respectively of the triangle ABC.

Con. DE is parallel to BC and equal to one-half of BC.

Hint. Take F, the midpoint of BC, and draw DF and EF. DE is parallel to BC, EF is parallel to AB, and DF is parallel to AC. (§182, Theorem 63. If a straight line divides two sides of a triangle proportionally, it is parallel to the third side.) Hence both DEFB and DECF are parallelograms. Thus $DE=BF=FC$. Therefore $DE=\frac{1}{2}BC$.

271. Theorem.—If a line is parallel to one side of a triangle and bisects a second side it bisects the third side. This is a special case of §181.

272. Theorem.—The line joining the midpoints of the non-parallel sides of a trapezoid is parallel to the two bases and is equal to one-half of the sum of the bases.

Hyp. Given the trapezoid ABCD, with E and F the midpoints of the non-parallel sides AD and BC respectively. Let $AB=b_1$ and $DC=b_2$.

Con. EF is parallel to AB and DC.

$EF=\frac{1}{2}(b_1+b_2)$.

Hint. Draw AC and let G be the midpoint of AC. Draw EG, EG is parallel to DC and equal to one-half of it. (§270.) Draw FG. In the same way, FG is parallel to AB and equal to one-half of AB. GF is also parallel to DC. (§95, Theorem 19.) Hence GE and GF are parts of the same straight line. (§15, Postulate.) $EG=\frac{1}{2}b_2$,

$GF=\frac{1}{2}b_1$, thus $EG+GF=EF=\frac{1}{2}(b_1+b_2)$.

273 Theorem.—Two triangles which have their sides respectively parallel or perpendicular are similar. Hint. Prove the angles of one triangle equal the angles of the other and apply §186.

274. Lemma.—A lemma is a preparatory proposition laid down to shorten the demonstration of the main proposition which follows it.

275. Corollary.—A corollary is a consequence drawn immediately from a proposition. In the text books on geometry many theorems are followed by the statement of a particular case as a corollary.

276. Concyclic Points.—Three or more points which lie on a circle are called concylic points. In general four points chosen at random will not lie on a circle. When we do have four points on a circle there are many relations existing among the lines and angles which are determined by the four points. The consideration of such relations is beyond an elementary discussion of geometry.

277. Conclusion.—The reader who is interested in geometry will never need to grieve for more worlds to conquer, as did Alexander the Great. After the study of plane geometry, naturally comes the study of solid, or three dimensional geometry. In the developments of modern physics it is also convenient, and also almost necessary, to study the geometry of four, five and of any number of dimensions. This is carried out with the assistance of the methods of algebra in what is known as analytical geometry. Geometry also becomes involved in still greater difficulties, for in order that the laws of physics may assume simple forms under all conditions it appears necessary that so called non-euclidean geometries should be developed. Every surface has a geometry of its own. If one is walking in a mountainous country, the shortest distance between two points for a person constrained to walk always on the ground will no longer be a straight line but will be a curve. Three points on the ground will determine three of these shortest distances, bounding an area which we may call a triangle. However two triangles may have their sides equal without being either congruent or equal in area. The curve corresponding to a circle becomes a complicated curve. The reader may investigate a geometry of this kind by stretching strings on the surface of any solid, a taut string in contact with a smooth surface giving the shortest distance between two points. The plane geometry we have studied becomes a special case of this geometry when the surface on which the strings are stretched is a plane.

FORMULAS

278. Symbols.—

a,b,c = sides of a triangle ABC.
p = perimeter.
r = radius.
c = circumference of a circle.
d = diameter of a circle.
h = altitude.
$s=\frac{1}{2}(a+b+c)$.
K = area.
b = base of a triangle, parallelogram.
π = 3.14159..., $\frac{22}{7}$ approximately.

279. Length of Lines.—

Right triangle $a^2+b^2=c^2$. §211, Theorem 83.

Circle $c=\pi d=2\pi r$. §231, Theorem 91.

Equilateral triangle $h=\frac{1}{2}a\sqrt{3}$. §268.

Diagonal of a square $d=b\sqrt{2}$. §211, Theorem 83.

Altitude on side c $=h_c=\frac{2}{c}\sqrt{s(s-a)(s-b)(s-c)}$.

Meridian on side $c=m_c=\frac{1}{2}\sqrt{2(a^2+b^2)-c^2}$.

Bisector of the angle opposite $c=t_c=\frac{2}{a+b}\sqrt{abs(s-c)}$.

An arc $=\frac{\text{central angle}}{180^\circ}(r\pi)$.

280. Areas of Plane Figures.—

Rectangle bh. §203, Theorem 75.

Square b^2. §203, Theorem 75.

Parallelogram bh. §206, Theorem 78.

Triangle $\frac{1}{2}bh$. §207, Theorem 79.

Triangle $\sqrt{s(s-a)(s-b)(s-c)}$. §212.

Equilateral triangle $\frac{1}{4}a^2\sqrt{3}$. §268.

Trapezoid $\frac{1}{2}h(b_1+b_2)$. §208, Theorem 80.

Regular polygon $\frac{1}{2}p$(apothem). §228, Theorem 89.

Circle $\frac{1}{2}rc=\pi r^2$. §223, Theorem 93.

Sector of a circle $\frac{1}{2}r$(arc).

BOOK XI

SCIENCE

PURE science is a product of research, questioning nature in order to understand. To explain any phenomenon is to state its relationships to other known phenomena. The relationships most commonly sought are those of quantity, order and cause, existing or acting in time and space. A cause is any determining factor. The cause of any given phenomenon is the sum of all antecedent conditions necessary to bring about the given condition. If this definition is accepted, it becomes evident that the cause of any experience can never be stated in full, for, in a sense, everything is the cause of anything. Explanations, therefore, seek the nearest causes, or those which have been noticeably potent in bringing about the condition observed.

Pure science discovers and explains. Applied science puts the discoveries and the theories of research into practical use, through mechanical inventions. The first production of radium, for example, was a triumph of pure research; but it was promptly followed by mechanical applications resulting in such a commercial demand for radium as seriously to hamper further research in the important field of radioactivity.

Science as such always proceeds by observation of the phenomena to be explained. Experiment is the process of observing phenomena under such control as to permit repetition and variation at the will of the observer. Scientific laws, or laws of nature, are the summaries of observation and experiment approved by competent authorities at any given time.

The order of procedure in formulating natural law through experiment is: (1) recognition of the problem; (2) control of the situation; (3) observation of all possible combinations of the variables involved; (4) comparison of the records thus secured; (5) rejection of the irrelevant; (6) synthesis of the relevant; (7) testing of the hypothesis thus formed, by applying it to new cases.

By sufficiently tested evidence, hypotheses may be confirmed into theories, and theories may become laws.

Classification of the Sciences. Science (from the Latin *scire*, to know) is human experience, tested and set in order. It differs from creed (that which one believes), resting on bases other than human experience; it differs from philosophy (our generalization as to that which transcends or lies beyond human experience); it differs from mere fact or record not set in order; it differs from history in dealing properly with causes and effects shown in proper relations. It differs also from art, which is essentially action based on human knowledge. In common language, however, the art and the science on which it rests may often receive the same name, as in the case of agriculture, which word implies a science, or group of sciences, relating to the rearing of crops, and also the use of this classified knowledge, or science, in actual practice.

In the language of modern Europe, the names of most of the sciences are derived from Greek roots, the second element in each being λόγος, *logos*, a discourse. Thus osteology (ὀστέον, *osteon*, bone) is a discourse on bones; ornithology (ὄρνις, *ornis*, bird) a discourse on birds. More exactly we may say that osteology is the science of bones. Again as each science is to the individual man an object of study, osteology becomes pedagogically the study of bones. By the addition of *logy* to a Greek root, an indefinite number of additional words can be framed, and will be framed in the future as the need for expression shall arise. For example, we may have rhodology, the science or the study of roses; orchidology, the science or the study of orchids; cynology, the science or study of dogs.

Other names applied to sciences conventionally end in the termination *ics*, which forms in many cases a euphonic ending. Thus optics, the science of vision (ὤψ, *op*, eye); ceramics (κέραμος, *keramos*, a pitcher), the science of pottery. Other words of this sort might be readily devised, as rhodics, the study of roses. Still other terms end in English in *graphy* (γράφω, *grapho*, write), indicating that the science is accompanied by writings or drawings; thus geography, description of the earth, as distinguished from geology, the study or science of the earth (γῆ, *ge*, earth). Still other recognized names of science spring from various roots, mainly from the Greek.

Beginning with inorganic nature, we may make the following classification of those branches of science which have recognized names in the English language.

OUTLINE OF THE SCIENCES

Concerning the Heavens.

Astronomy; science or study of the stars.
- Cosmology; science of the universe.
- Uranography; science (mapping) of the heavens.

Concerning the Earth.

Geology; science of the earth.
- Anemology; science of winds.
- Climatology; science of climates.
- Crystallography; science of crystals.
- Epigene Geology; science of forces molding earth from without.
- Geodesy; science of the earth's surface.
- Geognosy; science of the materials of the earth.
- Geography; science of the earth and its life.
- Hydrography; science of the waters of the earth.
- Hypogene Geology; (Plutonics) science of forces molding earth from within.
- Lithology; science of rocks.
- Metallography; science of metals and alloys.
- Metallurgy; science of preparing metals from their ores.
- Meteorology; science of weather phenomena.
- Mineralogy; science of minerals.
- Oceanography; science of the oceans and their phenomena.
- Orography; science of the study of mountains, particularly their structure.
- Petrography; science of rock classification.
- Physiography; science of the physical features on the earth's surface (also called physical geography).
- Seismography; science of recording earth tremors.
- Seismology; science of earthquakes.
- Stratigraphy; science of earth strata.

Concerning Mass and Force.

Physics; science of inanimate matter, not involving chemical changes.
- Acoustics; science of sound.
- Astrophysics; the science of physical constitution of the heavenly bodies.
- Calorifics; science of heat.
- Dynamics; science of motion of bodies, and action of forces.
- Electricity; the science of the phenomena and laws of electricity.
- Galvanism; the science of current electricity.
- Geophysics; science of agencies which modify the earth.
- Hydraulics, science of water in motion.
- Hydrodynamics; science of the relation of liquids and power.
- Hydromechanics; science of the mechanics of fluids.
- Hydrostatics; science of pressure and equilibrium of water.
- Magnetism; science of magnetic phenomena.
- Mechanics; science of action of forces on bodies.
- Optics; science of light and vision.
- Pneumatics; science of relations of gases to force or power.
- Thermodynamics; science of mechanical action or relations of heat.

Concerning the Molecules and Lesser Divisions of Matter.

Chemistry; science of the intimate composition and transformation of matter.
- Alchemy; science (and art) of the alleged transformation of baser metals into gold.
- Biochemistry; science of the chemistry of living organisms.
- Inorganic Chemistry; science of chemistry, excepting organic chemistry.
- Organic Chemistry; science of compounds produced in plants or animals and of various carbon compounds of artificial origin.
- Physical Chemistry; science of the relations between chemical and physical properties and phenomena.
- Physiological Chemistry; science of chemical processes within the bodies of animals.
- Spectroscopy; science of the spectra and the use of the spectroscope.

Concerning Living Organisms.

Biology; science of life and of living organisms (animals and plants).
- Analogy; science or study of resemblance in organs or parts of different structure or origin.
- Anatomy; science of the structure of living organisms.
- Bionomics; science of relationships of organisms to their environment.
- Comparative Anatomy; science of the relationships of forms of animals to each other and to man.
- Cytology; science of the structure and functions of the cells in living organisms.
- Dietetics; science of diet.
- Ecology; science of the adjustment or behavior toward environment of living organisms (used chiefly in reference to plants).
- Embryology; science of the development of the fertilized germ cell through different stages; the science of embryos.
- Environment; science of the effects of the results of external conditions in the development of individuals or species.*
- Heredity; science of continuity of type, from generation to generation (the name also applied to the law or fact of such continuity).*
- Histology; science of the minute structure of organic tissues.
- Homology; science of underlying resemblances in man or lower organisms, the supposed impress of common heredity.
- Hygiene; science of the methods of maintaining health (used chiefly in reference to man).
- Isolation; science of the results of the separation of individuals from the mass of the species.*
- Morphology; science of form and structure in living organisms.
- Ontogeny; science of the life history of the individual.
- Organic Evolution; science of orderly change in life forms from generation to generation (the name more often applied to the fact or process than to the science).
- Pathology; science of disease in organisms.

Phylogeny; science of the racial history or development of an organism.
Physiology; science of the functions of the living organs or organism.
Sanitation; science of the processes of maintaining healthful conditions for organisms (usually referring to man).
Selection; science of the results of the survival of one class of individuals as compared with others, from generation to generation.*
Taxonomy; science of the orderly arrangement of living beings according to their structure or according to their supposed origin or development. Classification is the general name for the processes of taxonomy.
Teleology; science of real or supposed purpose or adaptation in structures of men or lower organisms.
Teratology; science of monstrosities and their causes among men or other organisms.
Variation; science of individuality and the tendencies to divergence from generation to generation.*

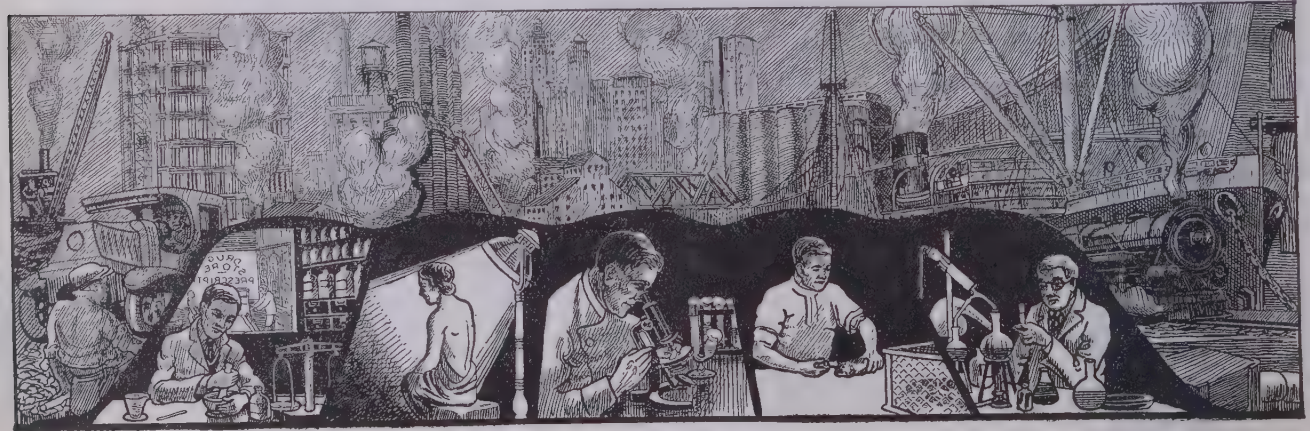
Sciences Chiefly or Wholly Related to Plants.

Botany; science of plants.
Abiogensis; science of (alleged) spontaneous generation of organisms.
Agriculture; science (and art) of cultivation of the ground, including the harvesting of crops and animal husbandry.
Agrostology; science of grasses.
Algology; science of algæ or seaweeds.
Arboriculture; science (and art) of shrub and tree culture.
Bacteriology; science of bacteria.
Bryology; science of mosses.
Dendrology; science of shrubs and trees.
Diatomology; science of diatoms, minute one-celled plants.
Forestry; science (and art) or care and culture of forests.
Horticulture; science (and art) of garden and orchard culture.
Lichenology; science of lichens.
Limnology; science of or study of fresh waters, as ponds and lakes, especially their biologic conditions.
Mycology; science of fungi.
Paleobotany; science of extinct vegetation.
Phytogeography; science of the geographical distribution of plants.
Pteridology; science of ferns.
Xerophytology; science of desert vegetation.

Sciences Primarily Concerning the Lower Animals or Concerning Man as an Organism.

Zoölogy; science of animals.
Androgyny; science of hermaphroditism.†
Animal Psychology; science of comparative psychology applied to animals.
Carcinology; science of crustaceans (crabs, lobsters, etc.).
Conchology; science of shells or molluscs.
Craniology; science of skulls.
Dermatology; science of the skin, its functions and diseases.†
Entomology; science of insects.
Gastrology; science of the stomach.
Gynecology; science of female diseases.
Helminthology; science of worms.
Herpetology; science of reptiles.
Ichthyology; science of fishes.
Laryngology; science of the throat and its diseases.
Mammalogy; science of mammals.
Myology; science of muscles.
Neurology; science of nerves.
Obstetrics; science of the process of birth.†
Odontology; science of the teeth.
Oölogy; science of eggs.
Ophthalmology; science of the eye, its structure, functions and diseases.
Organology; science of the organs.†
Ornithology; science of birds.
Osteology; science of bones.
Otology; science of the ear and its diseases.
Paleontology; science or study of past geologic period as shown by fossils of organisms.
Paleozoölogy; science of fossil animals.
Parasitology; science of parasites.
Pisciculture; science (and art) of rearing fishes.
Protozoölogy; science of protozoans.
Rhinology; science of the nasal apparatus and its diseases.
Skeletology; science of skeletons.†
Somatology; science of comparative study of the body.
Telegony; science of (alleged) effects of the first father on the progeny of a second, by the same mother.
Therology; same as mammalogy.
Thremmatology; the science of selective breeding of domestic plants or animals.
Trichology; science of the hair.
Zoögeography; science of geographical distribution of animals.

Sciences Relating Chiefly or Exclusively to Man as a Member of Society.



Anthropology; science of the human species.
Aeronautics; science (and art) of air flight.
Æsthetics; science of beauty and of appreciation of beauty.
Anthology; science of flowers—used chiefly for flowers of expression or choice lyric verse.
Apologetics; science of defense of the divine origin and authority of Christianity.
Archæology; science of ancient works of men.
Archæsthetics; science of the supposed pervading mind preceding the existence of conscious animal life.
Assyriology; science of ancient relics of Assyrian civilization.
Astrology; science of the imaginary influences of the stars on human affairs.
Athletics; science (and art) of bodily exercise.
Biography; science of individual life records.
Demonology; science of (supposed) spirits, mostly evil.
Dialectics; science of reasoning.
Didactics; science (and art) of instruction.
Dogmatics; science of asserted truths.
Ceramics; science (and art) of making pottery and other clay products.
Chronology; science of time.
Civics; science of civil relations of man.
Cookery; science (and art) of preparing food for man with the aid of heat.
Criminology; science of crime and criminals.
Economics; science of property relations of man.
Education; science (and art) of mental development in man.
Egyptology; science of ancient Egyptian civilization.
Epistemology; science of sources of human knowledge.
Eschatology; science of "doctrines of uttermost things," more especially speculations as to a future state.
Ethics; science (and art) of moral duty.
Ethnography; descriptive science of men, races and tribes of men.
Ethnology; science of the significances of races of men.
Ethology; science of human behavior.
Etymology; science of word-derivation.
Eugenics; science of the conditions of being well born, as regards possibilities of development in the individual life through heredity.
Euthenics; science of being well bred, or race improvement through environment.
Finance; science of the management of money.
Genealogy; science of tracing and recording pedigrees.
Genesis; science of origins.
Glyptology; science of engraving as on precious stones.
Graphics; science of drawing; especially in mathematics.
Gymnastics; science (and art) of bodily exercises.
Hagiology; science of saints and writings regarded as sacred.
Harmonics; science of music and of harmony in sound.
Hellenics; science of Greek culture.
Hermeneutics; science (or art) of expounding sacred writings.
Homiletics; science (and art) of preaching.
Hymnology; science of hymns.
Jurisprudence; science (and philosophy) of law.
Linguistics; science of languages.
Logic; science of exact reasoning.
Medicine; science (and art) of prevention, healing or alleviation of disease.
Metaphysics; study of matters that transcend physical knowledge.
Military Science; science of war and of methods of human destruction.
Mythology; science of myths and legends.
Papyrology; science of papyri.
Pedagogics; science (or art) of teaching.
Pediatrics; science of hygiene and diseases of childhood.
Pedology; same as pediatrics. (Also the science of the study of soils.)
Pharmaceutics; science of preparing, using or dispensing medicines.
Pharmacology; science of drugs, including materia medica and therapeutics.
Philology; science of words and word evolution.
Philosophy; a study of general conceptions which transcend human experience.
Phonetics; science of sounds, especially speech sounds.
Phonics; science of speech sounds.
Phonology; science of speech sounds, including history and theory of sound changes.
Politics; science of relations of men as citizens and as groups of citizens; the science of government.
Psychiatrics; science of mental disorders.
Psychology; science of the mind.
Psychotherapeutics; science of healing by action on the mind.
Pugilistics; science (and art) of fist-fighting.
Sociology; a group of sciences concerning human society.
Splanchnology; science of the internal organs or viscera.
Surgery; science (and art) of healing through cutting diseased or injured tissues or organs.
Telegraphy; science (and art) of "distance-writing" by the use of the telegraph.
Telepathy; science of (alleged) transmission of knowledge without the use of sense organs.
Telephony; science (and art) of "distance-speaking" by means of the telephone.
Theology; science of deity and of divine control of the universe; also of the opinions entertained by men in regard to these matters.
Therapeutics; science of healing agencies.
Toxicology; science of poisons and their antidotes.
Veterinary Medicine; science (and art) of healing disease in domestic animals.

Exact Sciences.

Mathematics; science of the exact relations between quantities or magnitudes and operations; the science of order.
Algebra; mathematical science treating of the relations and properties of quantities by means of symbols, letters, etc.
Arithmetic; science of numbers.
Calculus; science of calculation of problems involving motion or constant variation.
Geometry; science of measurements of space.
Horology; science of measuring time or of making timepieces.
Trigonometry; science of measurement of angles.

*The terms Environment, Heredity, Isolation, Selection and Variation are used more generally in the sense of factors in organic evolution of species or types.

†The terms Androgyny, Dermatology, Gynecology, Laryngology, Obstetrics, Opthalmology, Organology, and Somatology are applied chiefly to man, constituting branches of medical science.

Science in the Service of the World

ASTRONOMY

ASTRONOMY is the science of the heavenly bodies. The term is derived from two Greek words—*astron*, a star, and *nomos*, a law. The heavenly bodies are the Sun, planets, satellites, comets, meteors, stars and nebulae.

The Solar System comprises the Sun and the bodies which hold allegiance to it. They are the planets with their attendant satellites; the asteroids; and the comets and meteors, which also revolve about the Sun, but are bodies of a nature very different from that of the planets. The Earth on which we live is one of the eight planets revolving about the Sun, and the Moon is the Earth's only satellite.

The Sidereal System, of which the Solar System is a very small part, includes the stars, the clusters and many of the nebulae. The nebulae which do not belong to the region of the stars are in themselves other sidereal systems, probably similar to our own great star system.

The science of astronomy is a study of these bodies—their positions, distances, motions, dimensions, composition, physical condition, and the dynamical and physical laws which govern their motions and development. Astronomy utilizes information gathered in the fields of mathematics, physics, chemistry, geology, and biology; and in turn it unfolds to these sciences phenomena which prevail under conditions found in the Sun, stars and nebulae, and which cannot be duplicated on the Earth.

Astronomy is the oldest of sciences, and perhaps the noblest, for its scope is the entire visible universe. Other sciences restrict themselves, almost exclusively, to some one phase of nature on the Earth which, from the point of view of size, is an insignificant part of the whole universe. Astronomy, however, unravels secrets of nature not only upon the Earth but also throughout all space within reach of the most powerful instruments.

But to suppose that astronomy has no everyday uses is a mistake. Some of the most fundamental phases of our daily life and of modern commerce depend entirely on astronomy. Only by astronomical determinations are the latitudes and longitudes of places on the Earth established; and by the same means vessels at sea and caravans on the desert are guided in their courses. The determination of time, land surveys, the establishment of boundaries, map-making, prediction of tides, the knowledge of the shape and size of the Earth—all rest on observations of the heavenly bodies.

The fundamental time unit is the rotation of the Earth, and the position of any spot on the Earth at any time with reference to the heavens determines the time of day at that particular place. Today, with the radio to transmit time signals, fewer time determinations are necessary; but the clocks from which the signals are sent give accurate time only because they have been set by means of observations of the stars made with an astronomer's transit instrument. The official time of all civilized countries is obtained from the clocks in the astronomical observatories. The United States Naval Observatory, at Washington, D. C., maintains such a service, as do all the great national observatories, and many independent ones. The month and the year—larger units of time—depend not upon the rotation of the Earth, but upon the revolution of the Moon about the Earth and of the Earth about the Sun, respectively.

In the future, astronomy may also develop a great service to mankind by establishing a correlation between the amount of heat from the Sun and temperature on the Earth. This will make possible long-range weather forecasting. We may say that at present, this is little more than a hope, but a hope, nevertheless, which may be realized in the lives of some who read these pages.

ASTRONOMICAL INSTRUMENTS

Telescopes. Most astronomical information is obtained from the use of telescopes. They are of two general types—refractors and reflectors.

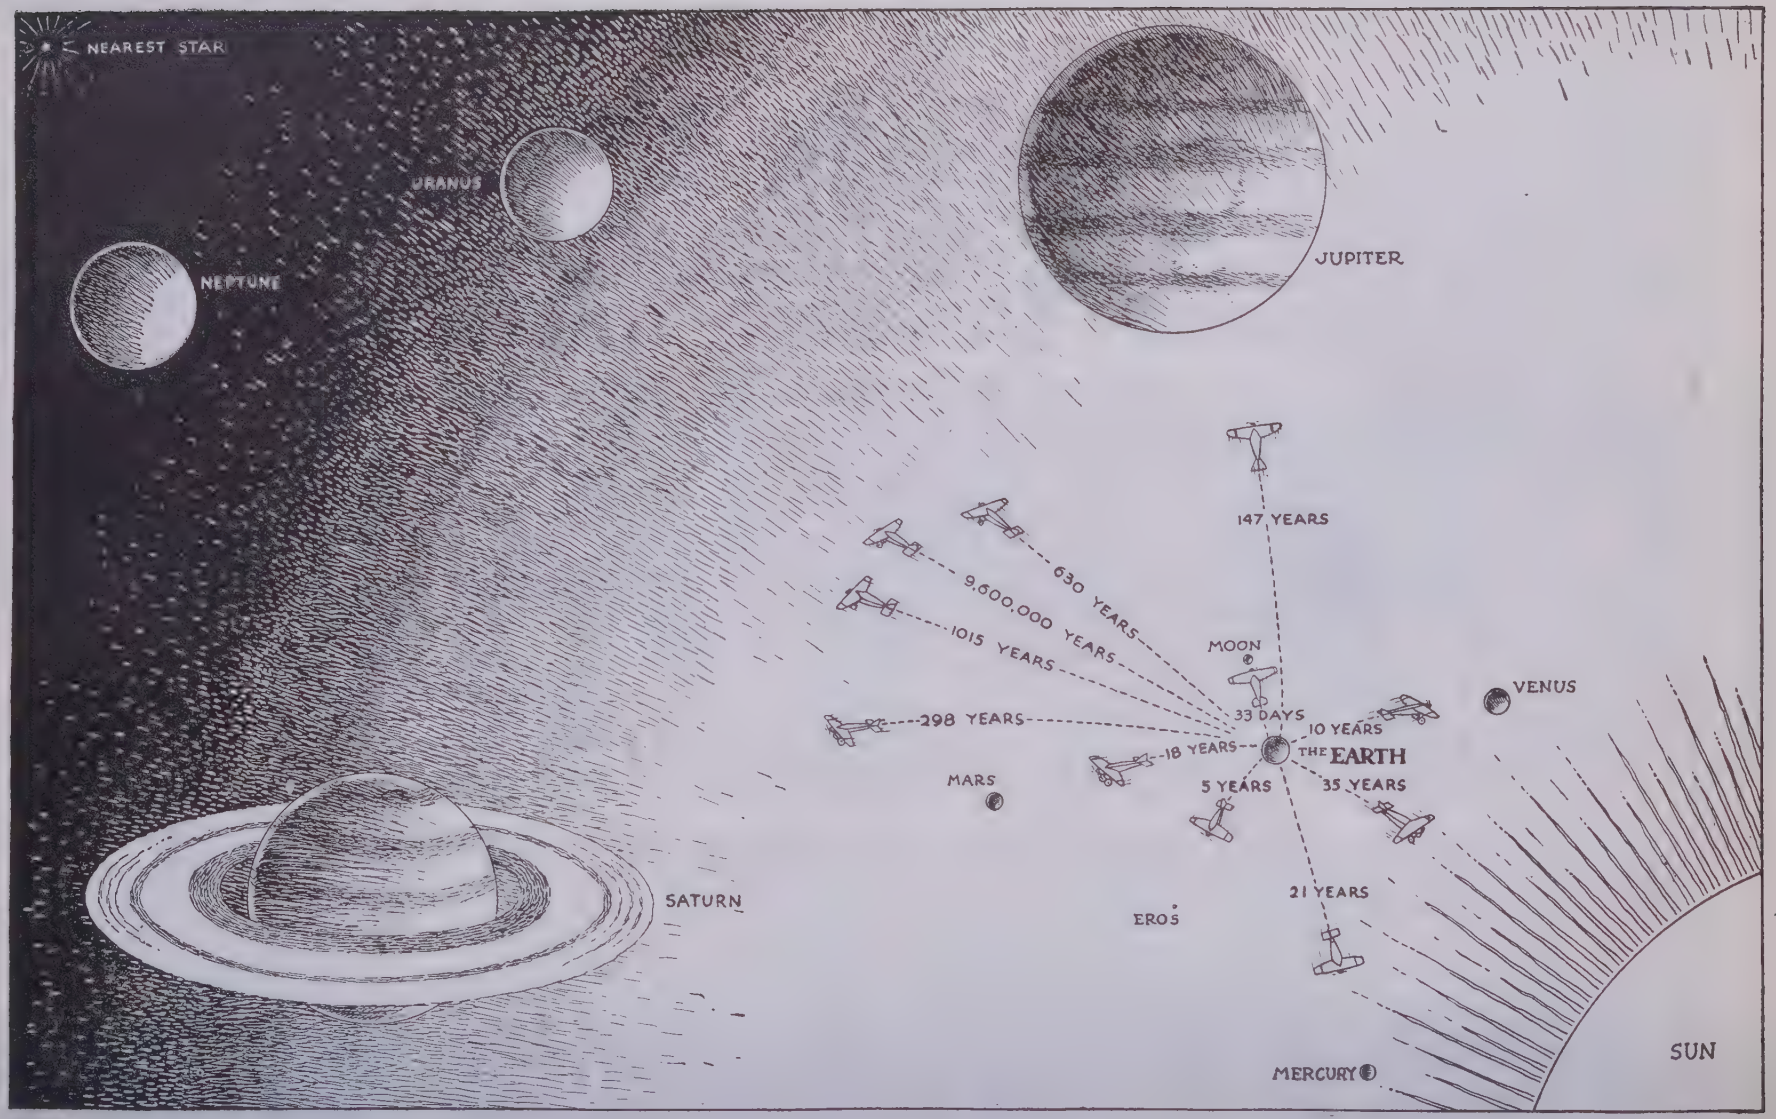
In a refractor the image is formed by a lens, the light actually passing through the glass and being bent, or refracted, to form the image in the focal plane. The lens requires optical glass of the highest quality, which must be of like density throughout and without mechanical strains. It is very difficult to produce large disks of optical glass of sufficient homogeneity for the demands of astronomical lenses. Inasmuch as it is impossible to unite all of the colors into one focal image with a single lens, the modern telescopic object glass consists of two or more lenses in combination. Such a lens system gives a well defined image of large field, free from spherical and chromatic aberration.

In a reflector, the light does not pass through the object glass. As the name implies, the light is reflected from a polished surface. With this idea in view, it is seen that it is unnecessary for the material to be optically homogeneous. It is, of course, desirable that it should be free from mechanical strains. Various materials have been used for the mirrors, but the largest ones have been made from speculum metal and from glass upon which has been deposited a silver surface. The silver surface, when burnished and free from tarnish, has a higher reflecting power than the speculum metal and is therefore to be preferred. Experiments are now being made with pyrex, quartz, stainless steel and stellite, in the hope of finding a material less susceptible to distortions due to rapid changes of temperature.

Regardless of whether it is a lens or a mirror which forms the image in a telescope, it may be mounted to permit pointing it to any region of the sky. In a fixed observatory the type of mounting universally adopted is known as the *equatorial*. Such a mounting has two axes, one parallel to the Earth's axis and known as the *polar axis*, the other perpendicular to it, known as the *declination axis*. Rotation about the declination axis produces motion in a north-and-south direction, and rotation about the polar axis produces motion in an east-and-west direction. The advantage of this form of mounting is that, once the telescope is directed toward a star, it may be made to follow it by driving the telescope with clockwork about the polar axis, thereby compensating for the rotation of the Earth.

Refractors and *reflectors* have their relative advantages and disadvantages. The refractor gives finer definition and a much larger field of fine definition. It is, however, more costly because of the necessity of using optical glass and because of the fact that four surfaces must be polished. Also, the tube must be longer (which necessitates a larger dome), because for a given aperture the *focal length* of reflectors can be made much shorter than for refractors. The refractor has these advantages, however; the surfaces, once ground and polished, are permanent; and the quality of the image is far less affected by changes of temperature. Perhaps in the 40-inch telescope of the Yerkes Observatory the limit of size for refractors has been nearly attained. Of course it is understood that the lens must be supported from the margin, and that in different positions, as it is pointed to different parts of the sky—standing on edge when pointed toward the horizon, and lying flat in its support when pointed toward the zenith—there may well be deformations which will affect the character of the image.

Reflectors have the advantage of perfect achromatism, that is, all colors are united into one focal image. Moreover, reflectors are cheaper, and they may be mounted so that there will be no sagging from changing position. They have the disadvantages of small field because of spherical aberration; distortion due to change of temperature; and non-permanence of the silver surface, necessitating frequent resilvering.



The Spectrograph. Another instrument which has wide application and is of great importance in astronomy is the spectrograph. It is generally used in connection with a telescope. The simple principles may be briefly stated:

If light from any source is passed through a prism it is spread out into a spectrum, with its constituent colors ranged in the order, red, orange, yellow, green, blue, violet, indigo. These colors represent the various wave-lengths of light, the waves of the red being about double the length of those in the violet. The location of any radiation within the spectrum defines its wave-length, and vice versa. For some luminous substances this band of color will not be continuous, but will present only isolated lines. In this phenomenon rests the possibility of spectrum analysis. The fundamental laws may be stated as follows:

(1) A gas under pressure, a liquid, or a solid when luminescent, gives a continuous spectrum, an unbroken sequence of colors from red to violet. For substances in these physical states there is no possibility of telling the spectrum of one from that of another.

(2) A gas under low pressure, when excited to luminescence, gives a discontinuous, or bright-line, spectrum; that is, only lines of certain wave-lengths appear in the spectrum, and these lines are characteristic of the gas under examination. Such a luminous source writes its own signature for its identification.

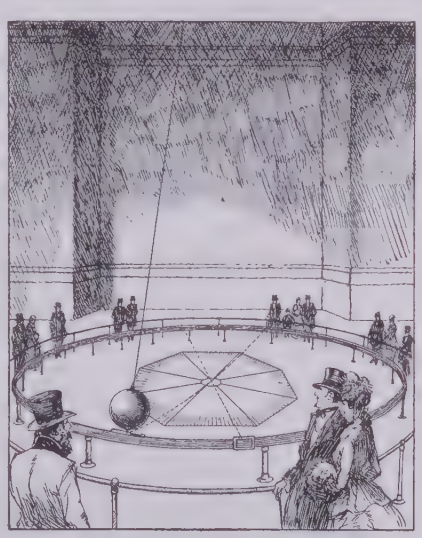
(3) If the light from the source giving the

Distances to Sun, Moon, Planets and Nearest Star

The artist has shown diagrammatically the distances to our Sun and Moon and to the planets (at nearest approach to Earth) and the nearest star. The airplanes are traveling at the rate of 300 miles an hour. The planets are shown in approximately relative sizes. Eros is the asteroid which approaches nearest to Earth.

continuous spectrum is observed through a layer of cooler gases under low pressure, this layer of gas will absorb from the spectrum just those lines which it would itself emit if it were isolated and luminescent. The result is a dark-line, or absorption spectrum.

Two additional principles of spectroscopy which have a wide application should be stated. The lines of the spectrum of the various elements occupy definite and fixed places in the spectrum under fixed conditions. But if the observer and light source are relatively approaching each other, the lines are shifted toward the violet; if receding, they are shifted toward the red. The amount of the shift is dependent upon the relative velocity. Application of this principle provides the possibility of determining the velocity of the stars toward or from the Earth and may also, as noted subsequently, be used to determine the velocity of the Earth in its orbit. A further principle states that the location of the most intense part of the spectrum is dependent upon the temperature of the light source. If the temperature is low, this maximum intensity of radiation will be in the red. As the temperature increases, the maximum intensity shifts toward the blue. This principle furnishes a direct means of determining the temperature of the Sun and stars.



THE SOLAR SYSTEM

It is necessary first to learn something about the Earth since all we know about any of the heavenly bodies depends upon observations made at its surface.

The Earth is a great ball, approximately spherical, with an average diameter of 7,918 miles. It is flattened slightly at the poles, the polar diameter being 7,900 miles and the equatorial 7,927 miles. It is 5.53 times as heavy as the same volume of water would be, and weighs six thousand millions of millions of millions of tons: the figure is written six with twenty-one ciphers. This great globe spins on its axis once in twenty-four hours. It makes its journey eastward around the Sun in a year at a rate of eighteen and one-half miles a second, or nearly 100,000 feet per second—about twenty times as fast as the swiftest modern projectiles.

When Magellan's ships actually sailed around the Earth in 1519-'22, the fact was established that the Earth is spherical. Two or three other familiar proofs of approximate sphericity were known even before that time. If an observer, anywhere on the Earth, increases his elevation, the visible horizon becomes more and more depressed below the true horizon. Also, as a ship goes out to sea, the highest portions remain longest in view and the tops of the smoke stacks and masts disappear last, showing that the surface is convex. Another proof is observable at times of lunar eclipse. The Moon must come into the Earth's shadow in order to be eclipsed so if we note the shape of the edge of that shadow on the Moon, we will know the shape of the body casting the shadow. It is always seen to be the arc of a circle.

To determine the size and shape of the Earth it is necessary to measure the length, in miles, of one degree at different parts of the Earth's surface. Two stations are selected hundreds of miles apart. The latitudes have been determined independently, which gives the distance in degrees. Then, to find the equivalent distance in miles, measurement is necessary. This measurement can not be done directly by chaining; but a process called *triangulation* must be employed. A short base line is measured with very high precision, and a system of triangles is built up on this base line, angles being measured at the two ends of one base in each triangle. The chain of triangles finally connects the two stations whose separation in miles is desired. The accuracy is such that the error is not greater than one inch in twenty miles. From these determinations, one degree of latitude at the equator equals 68.71 miles; at forty-five degrees latitude it equals 69.06 miles; at the poles, 69.41 miles. Arcs of longitude at any particular latitude are found to be of uniform length in miles.

Proof of Rotation of Earth

Foucault's famous experiment in the Pantheon, Paris, in 1851. The plane of the free swinging pendulum appeared to deviate slowly to the right. A similar Foucault pendulum is exhibited in the National Academy of Sciences, Washington.

No scale has weighed, directly, the entire Earth. But its mass has been determined by very delicate and accurate experiments which are based upon the Law of Universal Gravitation: ANY TWO PARTICLES OF MATTER ATTRACT EACH OTHER WITH A FORCE PROPORTIONAL TO THEIR MASSES AND INVERSELY PROPORTIONAL TO THE SQUARE OF THE DISTANCE BETWEEN THEM. The attraction of the Earth for a small body of known mass is compared with the mutual attraction of two such bodies. The description of these experiments is beyond the scope of this book.

Knowing the volume and mass, the average density of the Earth is derived from the relation: density equals mass divided by volume. The density of the Earth's surface rocks is found directly to be 2.75 times that of water. Since the mean density is 5.53 times that of water, we deduce that the central core of the Earth has a density of 10, and must be made of very heavy elements, probably largely of iron.

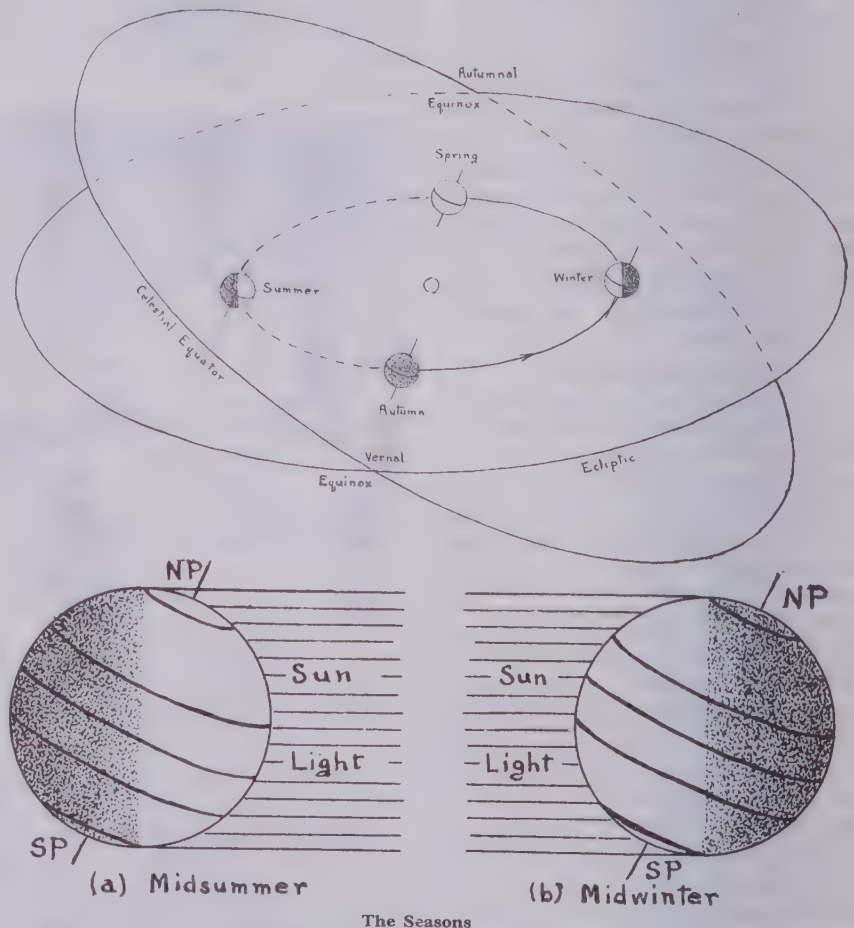
If we watch the stars for only a few hours we see that, with relation one to another, they remain unchanged; but their places in the sky are changing, moving slowly westward. The ancients believed the stars to be attached to a material sphere which turned on pivots. Either this is the case, or the Earth itself rotates on an axis. After the invention of the telescope it was seen that many of the planets are rotating globes, and it was natural to assume that the Earth, also, rotates. But now we have physical proofs that the Earth rotates, and these proofs are not dependent upon observations of any other heavenly body.

We shall consider just one of them, the experiment first performed by the French physicist, Foucault, in 1851. He hung a heavy iron ball, about a foot in diameter, by a wire more than 200 feet long from the dome of the Pantheon, in Paris. With great care the pendulum was started, equally free to swing in any plane; and as it swung, a pin fastened in the bottom of the ball cut a path in a ridge of sand. The plane of the swing turned slowly to the right, in the direction of the hands of a watch, at such a rate that it would have been carried completely around in thirty-two hours if it had not first come to rest. The floor was turning under the pendulum; the Earth was rotating. It will be seen that at the poles, the Earth would turn around under such a pendulum once in twenty-four hours; with decreasing latitude the time of rotation of the plane would increase, up to infinity at the equator, where there would be no shift at all. At the South Pole, the rotation would appear to be reversed. At the pole, the pendulum would deviate fifteen degrees an hour. The Foucault pendulum, in the National Academy of Sciences in Washington, D.C., deviates a little less than nine and one-half degrees an hour.

As the heavens are seen to rotate daily, so the Sun is seen to have an annual motion north and south of the equator and eastward among the stars. In spring, certain constellations are left in the sky after sunset; in summer, certain others; and so on throughout the year, winter nine o'clock skies being entirely different from the summer ones at the same hour. As far as the apparent motion goes, it could as well be due to the Sun going around the Earth as the Earth about the Sun. When the Earth was considered to be fixed at the center of the universe, the Sun was supposed to do the moving. Ptolemy (100-170 A.D.) worked out a very complete explanation of the apparent motions of all the members of the solar system on this basis. The Copernican system, announced thirteen centuries later, showed that the apparent motions could be explained more reasonably and simply by assuming the Earth to be one of the planets going about the Sun. By using telescopes and other astronomical instruments, and by employing modern methods, exact measurements have been made possible which have led to the discovery of three independent phenomena which demonstrate that it is the Earth, and not the Sun, that moves in a great orbit.

The first definite proof that the Earth revolves about the Sun was discovered by the English astronomer, Bradley, in 1726. It depends upon the phenomenon, *aberration of light.* For a description of this proof the reader is referred to any college textbook on astronomy. It will be seen that the velocity of the Earth in its orbit is obtained directly

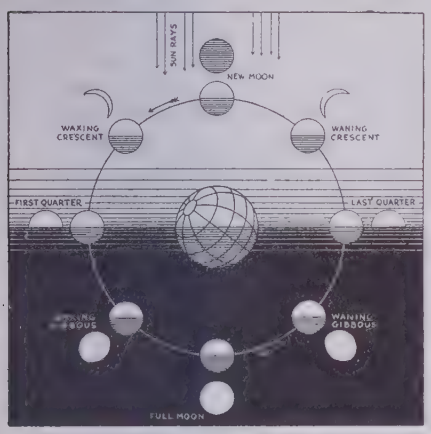
when the velocity of light is known. Then, knowing the time it takes to make one complete revolution, the distance around is determined; and from that, the radius of the orbit, or the mean distance of the Earth from the Sun—92,900,000 miles—is ascertained. This distance is called the *astronomical unit.*



The two other phenomena which constitute direct proofs of the Earth's orbital motion are the regular annual *shift of the lines* in the spectra of stars, and the annual *parallactic displacement* of the stars. The basis for the first proof is indicated under spectrum analysis. Like the aberration of light, it also provides a means of determining the distance to the Sun if the velocity of light is known. The second proof is explained under the subject of methods for finding stellar distances.

Seasons. If it happened that the equator were in the plane of the great path of the Earth about the Sun, there could be no change of seasons such as we have now, and days and nights would always be equal in length. But since the equator makes an angle of twenty-three and one-half degrees with the *ecliptic*, which is the apparent path of the Sun among the stars, and since it faces (except for the slow precessional motion) always in the same direction, there are only two times in the year, March 21 and September 21, when the Sun shines perpendicularly on the equator. These are indicated as the spring and autumn positions of the Earth, respectively, in the accompanying diagram of the seasons. At the summer solstice, June 21, the Sun shines twenty-three and one-half degrees beyond the North Pole, and falls short of shining on the South Pole by the same amount. Six months later, the opposite circumstance prevails. It is then winter in the Northern Hemisphere; summer, in the Southern.

It will be clearly seen from the lower shaded diagrams that any point in the Northern Hemisphere has sunlight for a longer time than it is without sunlight on all the days between March 21 and September 21, the greatest difference coming on June 21, when the Sun is highest in the sky at noon. During the other half of the year the reverse condition is true, the duration of sunlight being the shortest on December 21, at which time it is only about seven and one-half hours in the latitude of Chicago and New York. In summer, more heat is received from the Sun every twenty-four hours than is radiated away; as a result, the temperature continues to rise until the amount of heat lost in twenty-four hours equals that received. In our latitude this occurs about August first and not on June twenty-first as one might suppose from the fact that the most heat is received in twenty-four hours on that date. For similar reasons the minimum temperature of winter occurs about February first, and not on December twenty-first, when the daylight is shortest. Of course, elevation, winds and ocean currents affect the local temperature at any one place. The other factor that enters into the higher temperature of summer is the elevation of the Sun above the horizon. A beam of sun rays of given cross-section falls on a smaller area when it strikes the Earth's surface perpendicularly than when it strikes obliquely. Therefore, under high elevation, it will deliver more heat to a unit surface. This is also apparent from Figures *a* and *b* of the diagram of the seasons. A high sun, however, may furnish less heat during a short day than would a low sun shining through a long day. And so, in midsummer a region at the North Pole actually receives twenty-five per cent more heat from the Sun in twenty-four hours than does the same area at the equator. Summers at the North Pole would be hot if the heat were not used up in melting the great accumulation of ice.



The Moon. The Earth has one satellite, the Moon, which goes with it around the Sun. The Moon appears to us as large as the Sun, and next to the Sun its influence on human affairs is greatest of all the heavenly bodies. If the Moon were destroyed, maritime interests would be seriously affected, because the tides would be far smaller. The high water which tides provide for entrance to ports, and the natural dredging effect of the flow of tides, would be lessened. The Moon is conspicuous and important only because it is near; it is really small when compared with the planets, and insignificant when compared with the stars. The planet Mercury is one-half again as big, and Mars has twice the diameter; yet in considering the planets, we shall see that these two are the smallest. However, the phases of the Moon (the apparent changes in shape shown in a month); its movement among the stars, change of position with relation to the Sun; and its surface markings—all have engaged the attention of man ever since he could think.

Hold a new golf ball between the thumb and forefinger at arm's length, in line between your eyes and a lighted lamp, in an otherwise darkened room. If you are seated in a revolving chair, turn once completely around; or if standing, turn on your heel slowly, all the while watching the golf ball. You will have reproduced the effect of the phases of the Moon and demonstrated that they are due to the fact that the Moon is spherical in shape, that it shines only by reflected sunlight, and that it travels around the Earth in an orbit. In the first position the golf ball showed only its unilluminated side to you, and therefore appeared completely dark. In the corresponding position—Earth, Moon, Sun—we have *new moon*, and the Moon is said to be in *conjunction*. The next day, a very thin crescent hangs in the western sky after sunset. Each day the crescent increases in size and in distance east of the Sun until it is seen as a *half moon* on the meridian at sunset. This is *first quarter*, and the Moon is said to be in *east quadrature*. The phase continues to grow as the Moon moves eastward, more and more gibbous, until the illuminated face is turned full toward the Earth and we have

The Seasons
These diagrams are for the Northern Hemisphere.

full moon, and the Moon is in *opposition*. Then we have a waning gibbous Moon until it appears as a semicircle again. This is *third quarter*, or *last quarter*, and the Moon is said to be in *west quadrature*. Then it becomes a crescent again, narrowing until it disappears as a new Moon. It is this waning crescent which the fewest people see, for it rises later and later each night, from midnight to dawn.

Phases of the Moon
The sunlit side of the moon is presented differently to earth dwellers in different portions of its orbit.

Half of the Moon's sphere is always illuminated by the Sun; it is the portion, varying from none to all, of this illuminated hemisphere turned toward the Earth that causes the Moon's phases. The line which separates the sunlit portion which we see from the dark portion is called the *terminator*. In the two configurations—conjunction and opposition—the Moon is said to be in *syzygy*.

To determine the distance to the Moon is not a difficult astronomical problem. Two observers at stations situated on the same meridian, but widely separated in latitude, observe the Moon and measure its distance from the zenith. Then it is but a matter of the solution of three triangles to determine the distance to the Moon, which is found to be sixty times the radius of the Earth, or 239,000 miles.

The Moon's diameter, 2,160 miles, is a little more than a quarter that of the Earth. These 2,000 miles across the Moon, at its distance of 239,000 miles, appears as great to us (that is, subtend approximately the same angle) as does the 866,000-mile diameter of the Sun at 92,900,000 miles.

The Moon's mass is 1/81.5 that of the Earth, and accordingly it is not as dense, being only 3.39 times the density of water. Objects would weigh only one-sixth as much on the Moon as they do on the Earth; a man could jump six times as high on the Moon.

The Moon rotates on its axis once in twenty-seven and one-third days, and in exactly the same period of time goes once around the Earth, so that we see the same face turned toward the Earth at all times, except for small variations in motion, known as *librations*. Forty-one per cent of the Moon's surface is never visible to the Earth. The Moon's period of revolution is called a *sidereal month*. The time from a given phase, to the recurrence of it is twenty-nine and one-half days, and is called the *synodic month*. This forms the approximate basis for the unit of time known as our *calendar month*. The Moon's orbit is not exactly circular and it is inclined to the ecliptic at an angle of five degrees, roughly. The points where the two orbits cross are called the *nodes—ascending* when going from south to north, and *descending* when going from north to south.

When we look at the Moon through a telescope and thus magnify its surface features, we see the areas which are dark to the naked eye as smooth plains. Early astronomers thought they were seas and so called them *maria*, a name which persists in spite of the fact that there is no water on the Moon. What we see as bright areas are, in general, the rough features—mountains, craters and rills. The Moon's surface has been carefully mapped and all the features named. The most prominent *mountain ranges* are the Alps, Apennines and Caucasus.

Heights of mountains on the Moon are determined from the length of their shadows and by knowing how high above the lunar horizon the Sun would appear at that point; or from the distance of mountain peaks from the terminator, when the sunlight first strikes their summits. The highest lunar mountains are 25,000 feet or more.

Many thousands of *craters* are visible on photographs of the Moon which have been made with modern telescopes. These craters range in size from a few hundred feet across, to dimensions greater than some of our smaller states. The curvature of the Moon is such that to a person standing in the center of the giant craters the rim, unless exceptionally high, would be quite invisible. In the large craters, numerous smaller ones, as well as mountains are seen.

Over a thousand *rills* have been mapped. These are narrow crevices (ditches or furrows) less than two miles wide, and inconspicuous because they are so narrow. In length they are from ten to a hundred or more miles.

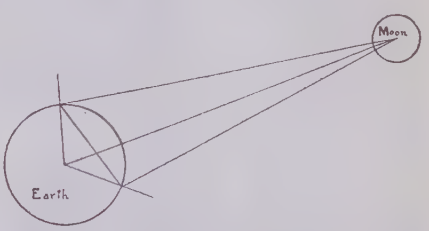
When the mountains, craters or rills on the Moon's surface are near the terminator, they are in the best position for observing.

From some of the prominent craters, especially Tycho, Kepler and Copernicus, narrow streaks are seen to radiate outward; these are called *rays*. When the Moon is full, these ray systems can be seen best.

The Moon is known to be without air and water; neither animal nor vegetable life can exist on it.

The Sun. To most persons the Sun is just a large orb that appears to cross our sky from east to west, giving light when it is visible, and regarded as responsible for the varying temperatures at any one place on the Earth and for the difference in climate at various places on the Earth.

Actually, the Sun is a star, so near to us that its brightness obscures the other stars except when we are on the side of the Earth turned away from it, which condition we call "night." The Sun appears to cross our sky because the Earth turns on its axis, now presenting one-half of its spherical surface to the Sun's rays, and twelve hours later presenting the opposite half.



The Sun's attraction keeps the Earth, the seven other planets, and the comets and meteors in their orbits about it; it also influences the motions of the satellites. It is not impossible that other stars have systems of planets revolving about them, like our own, but we have nothing to prove this.

Our Sun is but an average star, medium in size and temperature. Yet, compared with the Earth and the other planets which circle about it, it is enormous and exceedingly hot. At the Sun's surface a shell of ice thirty-nine feet thick would melt in one minute. The Earth could not endure the Sun's great heat except for the distance which separates it from us—92,900,000 miles.

Knowing the distance to the Sun, we can readily determine how large it must be to appear the size it does. Its diameter is found to be 866,000 miles. If the Earth were placed at the center of the Sun, our Moon, at its present distance, would be only a little over half the distance to the surface of the Sun. And when we come to consider the volume of this huge ball, we find that more than a million Earths could be contained within its dimensions.

Its mass is 333,000 times the mass of the Earth, and from this we can see that a unit volume of it is only about one-fourth as heavy as the same volume of the Earth; or, it is only about one and one-half times as dense as water. But the entire mass is so great that an average man would weigh more than two tons at the surface of the Sun. Ninety-nine and six-sevenths per cent of all the mass in the solar system is contained in the Sun.

We cannot turn a telescope toward the Sun and proceed to examine its surface as we did in the case of the Moon, for the intense heat would destroy the observer's eye. An image of the Sun may be projected upon a white cardboard, and thus several persons can see it at one time and observe the rotation by the motion of the spots. They are seen to move faster at the equator than in higher latitudes, once around in twenty-five days at the Sun's equator, and in solar latitude forty-five degrees, once in twenty-seven and one-half days. So, because its parts move past one another, we know that the Sun cannot be solid; it is gaseous throughout, extremely hot at the center, with temperature about 10,000 degrees Fahrenheit at the surface.

Distance to the Moon
This diagram illustrates the method of determining the distance to the moon.

One can look at the Sun through a smoked glass or by putting a dark glass on a telescope. Also, a helioscope may be attached to the telescope for visual observations of the Sun. This latter device diverts most of the light to one side.

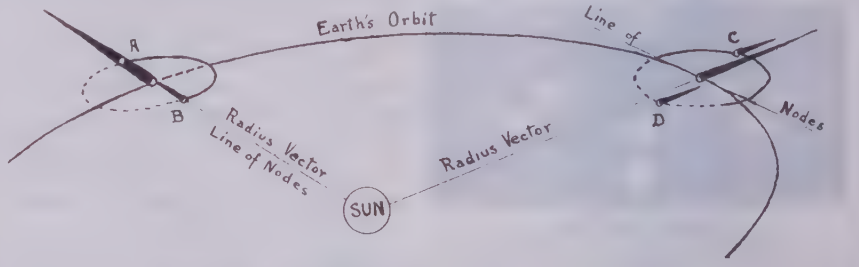
Photographs may be taken with a special camera and focal-plane shutter attached to a

telescope, and the details of the surface then studied at leisure. A very minute fraction of a second is required for a photograph, because the Sun is so bright.

A view of the Sun by any of the means above mentioned or a photograph of it, presents a brilliant circular disk, brighter at the center and darkening toward the edges, with a mottled, granular surface which we call the *photosphere*. On the photosphere are the dark sun spots. These vary greatly in size and shape, the larger ones stretching over more than 100,000 miles of the Sun's surface. Each spot has a dark center called the *umbra*, and a less dark region about it, called the *penumbra*. Sun spots start as small points, develop rapidly, last for a few hours, a few weeks, or a few months, and then break up and disappear. But the Sun seems not to become immune to spottedness: it passes through one cycle, lasting about eleven years, and even before that is over another begins. The spots of the new cycle are first seen in latitudes thirty to forty degrees north and south. As the period progresses, others break out at lesser and lesser latitudes until the solar equator is approached. The greatest number are present when the spot regions are at latitudes sixteen degrees. This is called a *sun spot maximum*. The most recent maximum was spread over the years 1927 and 1928. The time from a maximum to a minimum is longer than from a minimum to a maximum, 6.5 years and 4.6 years, respectively.

Besides the dark spots, there are bright areas visible on a direct photograph of the Sun. These are called *faculae* and are usually seen only near the limb because the background is darker there. When pictures of the Sun are taken in a single element, such as hydrogen or calcium, they are called *spectroheliograms*; and on such pictures the bright areas are called *flocculi*.

Above the Sun's surface, the photosphere, is a layer of permanent gases, called the *chromosphere*. The lower part of it is sometimes called the *reversing layer*. The origin of this name will be understood after the discussion of the solar spectrum below.



From the chromosphere rise vast, flame-like eruptions, called *prominences*. These vary in height, some having been known to rise 500,000 miles. They sometimes take on rapidly changing fantastic shapes, and at other times lie quiescent like clouds in the atmosphere.

The outermost layer of the Sun's atmosphere, the *corona*, can be seen only at times of total eclipse of the Sun, as a vast halo extending 300,000 miles all about it. Its shape varies with a period of approximately eleven years, corresponding to the sun spot cycle. It is controlled by the magnetic field of the Sun.

When the solar spectrum is observed with a suitable spectroscope, it is seen to have hundreds of dark lines. According to the third law of spectrum analysis, stated above, these are interpreted as being due to the absorption of an atmosphere of cooler gases overlying the photosphere. That this is the case has been amply demonstrated by observations made at time of solar eclipse. At the moment when the Moon has completely covered the photosphere and the atmosphere of permanent gases on the Sun alone are exposed to view, there suddenly appears a complex, bright-line spectrum and these bright lines are the exact counterparts of the dark lines of the ordinary solar spectrum. For obvious reasons it is called the *flash spectrum*.

Fifty-seven of the ninety terrestrial chemical elements have been detected in the Sun from a comparison of the lines of the solar spectrum with those of the various elements. It is reasonable to suppose that others may also be there but that we do not see their lines in the solar spectrum because of peculiar conditions of radiation due to temperature, pressure and so forth.

We have considered the dependence of our modern world upon astronomy for supplying it with time, directions, positions on the Earth and all resulting conditions; but when we come to consider the most important to us of all the heavenly bodies, our Sun, we readily recognize that except for it there would be no form of activity on our Earth. We depend upon the Sun for all power and warmth and life on the Earth. Our food, in all its forms, has had its origin in the same source. Our light and heat is one or another form of "canned sunlight." We have our very existence because of conditions for which the Sun is responsible. It is not difficult to understand why some races have worshiped the Sun.

Conditions for Eclipses
This diagram illustrates the conditions for lunar and solar eclipses.

Eclipses, both of the Sun and Moon, occur when certain geometrical conditions of relative position of Sun, Earth and Moon are fulfilled. In the eclipse diagram it will be seen that, on the side of the Earth opposite to the Sun, there is a cone of shadow. When the Moon, in its revolution about the Earth, comes into that shadow it is darkened, and we say it is eclipsed (Position A). When it is on the side of the Earth toward the Sun and comes into such a position as will cut off all or part of the Sun's light, we say the Sun is eclipsed (Position B).

It would appear at first glance that there would be an eclipse of the Moon at every full moon and an eclipse of the Sun at every new moon. But this is not the case because the Moon's orbit is inclined to the orbit of the Earth. If the full moon is not near the ascending or descending node of its orbit, it will be so far from the plane of the ecliptic that it will pass above or below the Earth's shadow and will not be eclipsed (Position C). If the new moon is not near one of the nodes, its shadow will pass above or below the Earth and the Sun will not be eclipsed (Position D).

If the shadow of the Earth and the full Moon are near enough to one of the nodes so that the Moon passes entirely into the shadow, a *total lunar eclipse* results. If only part of the Moon enters the shadow, a *partial eclipse* occurs. Most persons have witnessed a lunar eclipse, for the phenomenon can be seen by all the people on the night side of the Earth at the same instant. In fact, an eclipse of the Moon is visible to considerably more than a hemisphere because, in the four hours which may pass from the time the Moon first touches the shadow entering until it completely leaves it, the Earth has turned on its axis sixty degrees. There are between fifteen and sixteen lunar eclipses in ten years. The eastern side of the Moon becomes darker some time before it actually reaches the shadow; then a bite is taken out of the Moon's disk and this increases in size until the whole Moon is darkened. Presently, a small bright arc is seen to emerge on the opposite side, which grows until the whole lunar surface is again in sunlight. Very successful motion pictures of eclipses of the Moon have been secured.

If the new Moon's cone-shaped shadow does not pass above or below the Earth and is long enough to reach it, a *total eclipse of the Sun* occurs. The Sun is totally obscured for those parts of the Earth which the Moon's shadow touches. But if the new Moon's shadow is in line but falls short of reaching the Earth, as it often does, a ring of sunlight shows around the disk of the Moon, and this is called an *annular eclipse*. A solar eclipse is visible as total only within the narrow shadow path. For some hundreds of miles on either side of the shadow path, the Sun may be observed in partial eclipse. The shadow travels with high speed, and for any one place on the Earth the average duration is three minutes. At any one station a total eclipse of the Sun will be visible only once in three or four hundred years, on an average. And even if one travels far to the places where total solar eclipses are to be visible, he may be disappointed by clouds obscuring them. Many astronomers, even, have never witnessed the phenomenon.

In ancient times the sudden rush of darkness in a midday cloudless sky was attended by scenes of terror. It is surprising how early the ancient astronomers developed methods of prediction. Among the earliest records are found such predictions. In prehistoric times the Chaldeans had discovered that eclipses follow an orderly sequence with recurrence at intervals of eighteen years, eleven and one-third days. They named this period the *Saros*. Astronomers paid severe penalties for failure to fore-

tell, for it is recorded in ancient Chinese annals that the astronomers Ho and Hsi were beheaded upon the occurrence of the unannounced eclipse of 2137 B.C.

The Moon gradually encroaches on the solar disk and for a brief time—at most, seven minutes and forty seconds—completely covers it, then passes off to the other side. The phenomenon presents no especially interesting features until the stage of totality approaches. The exposed crescent of the Sun becomes narrower and narrower. At this time, because the light of the Sun's edge differs from that of the center of the disk, the landscape is seen in unusual hues. Images of the Sun formed through interstices in the foliage are crescent shaped. The unnatural light causes all animals to show uneasiness; fowls go to roost. Just before the beginning of totality, the crescent becomes broken and there appears along the edge of the Moon a series of bright points, called *Bailey's beads*, due to the Sun shining between the mountains on the edge of the Moon. If one stands on an elevation he may see the Moon's shadow rushing at a terrific speed over the landscape. On bright surfaces may be seen the rippling shadow bands, due to the uneven refraction of light from the narrow source through the Earth's atmosphere. Then comes totality, and with it the most beautiful phenomenon visible to human eyes—the solar corona—stretching out its tenuous filaments about the Sun. The degree of darkness depends upon the clearness of the atmosphere and the size of the shadow. In some cases, it is easily possible to read a watch; in others, lanterns are necessary if one would move about. There is generally a marked drop in temperature; dew is sometimes deposited. The end of totality comes with the same abruptness as does the beginning. The corona fades, and suddenly the edge of the Sun appears from behind the lunar disk, and the sequence of events at the beginning of eclipse is repeated in reverse. It is noticeable that human beings show the same release from tension that the animals have exhibited. In our day, the terror is gone; but the sense of awe remains. Foretold though it is, the very fulfillment of the prediction is tremendously impressive. The observer views the most beautiful of natural wonders, with the inexorable march of the shadow, the unnatural light, the strange actions of animals, the swift descent of darkness, the beauty of the prominences and corona, the view of the stars and the realization that they are always in the heavens, invisible only because of the brilliance of the sunlight flooded air.

The Planets. The eight principal planets in order of their distances from the Sun are: Mercury, Venus, Earth, Mars, Jupiter, Saturn, Uranus and Neptune. To the naked eye they appear as stars; but they may be distinguished from stars because they do not twinkle, and because they are seen to move among the stars. When looked at through a telescope, the planets present disks, whereas the stars appear as points of light because of their much greater distances.

Mercury and Venus, having their orbits inside that of the Earth, are classed as *Inner Planets*, and the other five as *Outer Planets*. Mercury, Venus, the Earth and Mars are more often grouped as *minor* or *terrestrial* planets; and Jupiter, Saturn, Uranus and Neptune, as *major planets*, or *giant planets*, because they are very much larger.

All the planets move about the Sun continuously from west to east, the innermost travelling at the highest speed. As we watch their changing positions, however, we note that they appear to move eastward for a time and then, at regular intervals, loop backward for a short distance before they proceed in the direct motion. This is due to the combination of motions of the Earth and planets. The orbits are all nearly circular and lie in nearly the same plane. They are all contained within a narrow belt of the sky, sixteen degrees wide, known as the *Zodiac*, the ecliptic passing through the middle of it.

Early in the seventeenth century Kepler announced three fundamental laws of planetary motion, as follows:

(1) The orbit of every planet is an ellipse with the Sun at one focus.

(2) The radius vector (the line connecting the Sun and the planet) sweeps over equal areas in equal times.

(3) The cubes of the mean distances of the planets from the Sun are proportional to the squares of their sidereal periods.

Now we shall consider the planets individually and comparatively. *Mercury* is the smallest of the planets. It travels at the highest speed in its orbit, which is inclined at the greatest angle to the Earth's orbit. It goes about the Sun once in eighty-eight days. Because of its comparatively small orbit, it is never seen far from the Sun. When it is at greatest elongation from the Sun, twenty-eight degrees, it is never very high above the horizon at sunset. For this reason it is difficult to observe. Consequently few people, comparatively speaking, have ever seen Mercury. Some astronomers have observed markings on its surface, but the markings are hazy and ill-defined.

Because their orbits are inside that of the Earth, Mercury and Venus show phases such as that of our Moon, from new to crescent, through half, gibbous, to full. Also, they are the only ones that can be seen to transit, that is, to cross the face of the Sun.

Venus is the planet most like the Earth in size and mass. It goes around the Sun once in 225 days. It is the most brilliant of the planets, being the only one which can be seen at midday. The brightness of Venus surpasses that of the brightest star, Sirius, nearly ten times. It approaches nearest to the Earth of any of the planets, and the difference in distance at nearest approach and when farthest away causes a six-fold difference in apparent diameter. Venus has a very abundant atmosphere; Mercury has none. Owing to Venus' cloud covered surface, it has not been possible to determine the length of its day by observing surface markings. As far as we know, neither Mercury nor Venus has a satellite. It is probable that both Mercury and Venus keep the same face continuously toward the Sun, as the Moon keeps the same face toward the Earth.

Mars appears like a very red star, bright and conspicuous. It resembles the star Antares, which was so named because of its similarity to Mars, Antares meaning "Rival of Mars." In the telescope, Mars shows the gibbous phase when at quadrature. Much popular interest centers in Mars, due to speculation concerning the possibility of life thereon. Telescopes have certainly revealed that Mars has polar caps which increase and diminish with the seasons, and that certain fine markings and even extensive regions on the planet undergo seasonal changes in color and conspicuousness. This phenomenon favors the idea of advance and decline of vegetation. In other words, it seems quite certain from this evidence that there is plant life on Mars. The presence of water vapor in the atmosphere of Mars, and temperatures on the planet, recently determined, increase the possibility. Where plant life exists, there is likely to be some form of animal life. The principal argument for intelligent life rests on the artificial appearance of the so-called canals.

The day on Mars is about forty minutes longer than our day. The Martian year is 687 days; so the seasons are almost twice as long as ours. The diameter of Mars is 4,230 miles, and its distance from the Sun is one and one-half astronomical units. Although only a little more than half as large as the Earth, Mars has two moons—Deimos and Phobos. But they are tiny moons, probably less than twenty miles in diameter, whereas our Moon is 2,160 miles in diameter. They can be seen only in a large telescope.

Asteroids. Between the orbit of Mars and that of the next major planet, Jupiter, is a gap in space in which are found a thousand and more little planets, called asteroids. Most of them are tiny objects when seen in the telescope, and can be distinguished from faint stars only by their motions. The brightest one, Vesta, when nearest the Earth, is sometimes visible to the naked eye. Two are larger than Vesta, though not so bright—Ceres, 488 miles in diameter, and Pallas, 304 miles in diameter. The asteroid Eros approaches the Earth as near as 13,000,000 miles, nearer than any heavenly body except the Moon. Observations made on this little planet at such times of close approach furnish the basis for the most accurate determinations we have of the distance of the Sun from the Earth.

Jupiter is the greatest planet in dimensions and in mass. Its diameter is 88,700 miles, eleven times that of the Earth; and in volume it is greater than all the other planets combined. It weighs 317 times as much as the Earth. At a distance of 5.2 astronomical units, it revolves about the Sun once in a little less than twelve years. It travels slowly and majestically through about thirty degrees, or one sign of the Zodiac, each year. Jupiter's day, however, is short—only about ten hours. To the naked eye Jupiter appears as a star five or six times as bright as Sirius, though not so bright as Venus. Its light is yellowish, whereas that of Venus is white. In any telescope an equatorial bulge on Jupiter is noticeable; and light and dark belts, parallel to its equator, are conspicuous. The oblateness is caused by the planet's rapid spinning on its axis. With a large telescope and with good seeing, the bands reveal delicate, beautiful structure with colors in red and brown. The most prominent persistent marking is the great red spot. Jupiter has nine satellites, five of which are very small. The four large ones—Io, Europa,

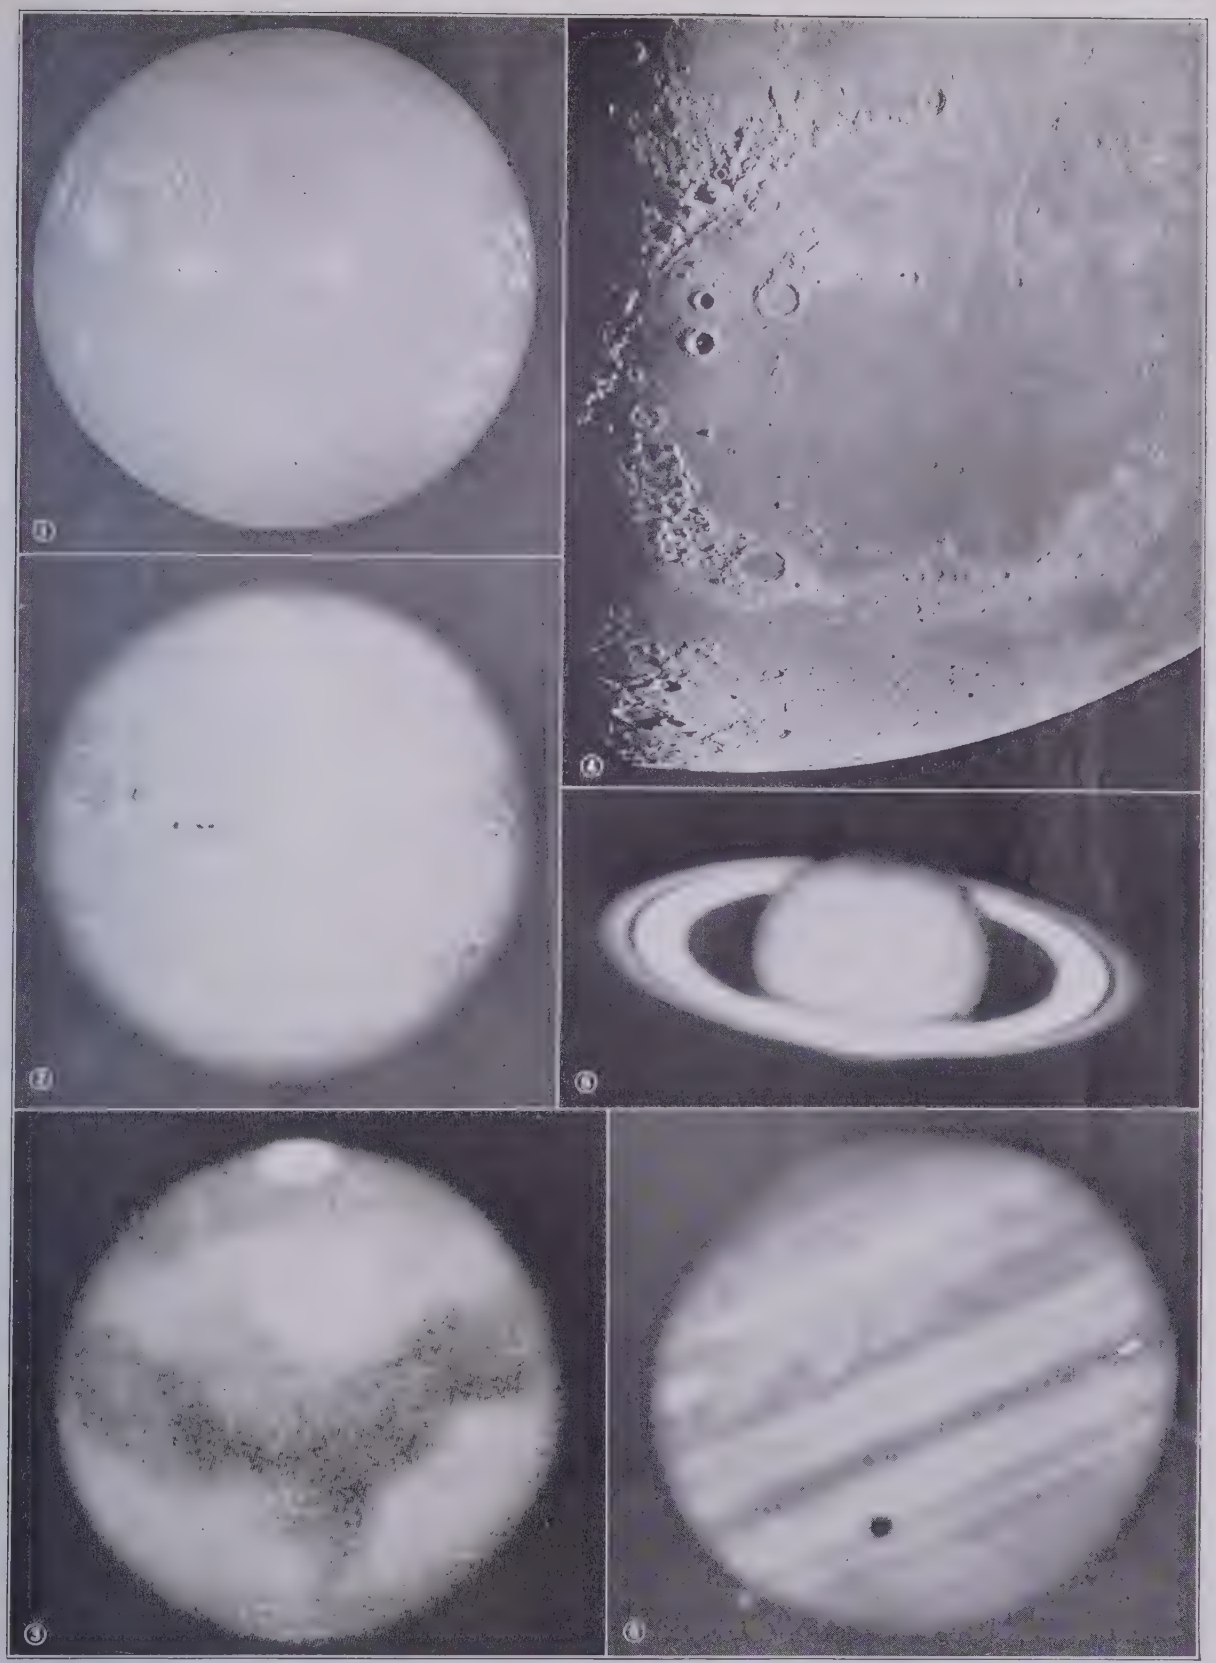
Ganymede and Callisto—are known as the *Galilean satellites* (discovered by Galileo in 1610). They were the first heavenly bodies discovered by means of the telescope, and their discovery constituted the first evidence that the Earth was not the center of the solar system. They are so bright as to be visible in the smallest telescope. These four satellites of Jupiter present a beautiful sight, and afford interesting phenomena for astronomical observation as they revolve about the planet, when the moons themselves and their shadows can be seen to cross the disk of Jupiter, and when the moons are occulted by the planet or eclipsed by its shadow. Observations of the eclipses of the Galilean satellites led to the first determination of the velocity of light.

Saturn, to the unaided eye, is most nearly like Mars of any of the planets, though not so ruddy nor so brilliant. It resembles the star Spica. Viewed in a telescope, Saturn is probably the most beautiful sight in the heavens. It presents a picture different from all other bodies in the universe—a globe encircled by a shining ring. The ball is striped with delicate bands, much fainter than those on Jupiter, and at times polar caps blue as a robin's egg are seen. The ring system is composed of two bright rings separated by *Cassini's Division*, and of one dusky, semi-transparent ring within them, nearest the ball, called the *crepe ring*. Saturn makes its trip around the Sun in nearly thirty years. Twice during this period the rings are presented edgewise to the Sun. At those times, and also when the Earth is in the plane of the rings, or when the Sun and Earth are on opposite sides of the rings, they can be seen only with difficulty or else they entirely disappear. Seven and one-half years later, the Earth and Sun look down on the rings from an elevation of about twenty-six degrees, and then they appear as an ellipse nearly half as wide as it is long. At this time the rings cast a shadow on the ball, and the ball casts a shadow on the rings. The rings are made up of small bodies, giving the appearance of a solid ring. The demonstration of the meteoric constitution of the rings is one of the triumphs of the application of the spectroscope to astronomy. Saturn is next largest to Jupiter, having a diameter of 75,000 miles. The distance between the outer limits of the ring system is more than twice this distance. Saturn's day, too, is short—about twenty minutes longer than that of Jupiter. The ball being less dense than Jupiter, this rapid spinning makes for even greater flattening at its poles. The bulging at its equator is easily visible in a telescopic view of the planet and on photographs of it. Saturn's density is less than that of water. The planet has nine moons, as has Jupiter; but only one of them, Titan, is as large as the Galilean satellites.

Uranus was discovered in 1781 by Sir William Herschel. The first six planets had been known always, hence the discovery of a planet was a thing unheard of, and the occasion of great excitement. Uranus can be seen with the naked eye on a moonless night if one knows just where to look for it. In a telescope it presents a light greenish disk, too small and too faint to reveal surface markings clearly, if there are any. Consequently it has not been possible to determine its rotation period by the usual method. Other determinations, spectroscopic and radiometric, indicate a period of between ten and eleven hours. Uranus has four tiny moons with beautiful names—Ariel, Umbriel, Titania and Oberon. These encircle it in periods varying from two and one-half days to thirteen days. Their orbits, and the equator of Uranus as well, are nearly perpendicular to the ecliptic. The planet itself goes around the Sun at a distance of nineteen astronomical units once in eighty-four years.

Neptune was discovered because Uranus was seen to deviate from the orbit computed for it from observations of its position made in the years immediately following its discovery, even though allowance had been made for the disturbing effect of all known planets. It was thought that some unknown body, near enough and of great mass, must be perturbing Uranus. In 1846, therefore, search for such a disturbing body in a position indicated by computations by Leverrier and Adams, revealed a planet beyond Uranus. This was a magnificent triumph for mathematical astronomy. The planet was named Neptune. It is the eighth planet to be discovered. It is not visible to the naked eye. In the telescope its appearance is not unlike that of Uranus—a pale greenish disk with markings, vague at best. Although its one satellite has a diameter almost equal to that of our Moon, its great distance from us makes it difficult to see. Neptune's period of rotation is unknown. It goes about the Sun once in 165 years at a distance of thirty astronomical units. In size, it almost equals Uranus.

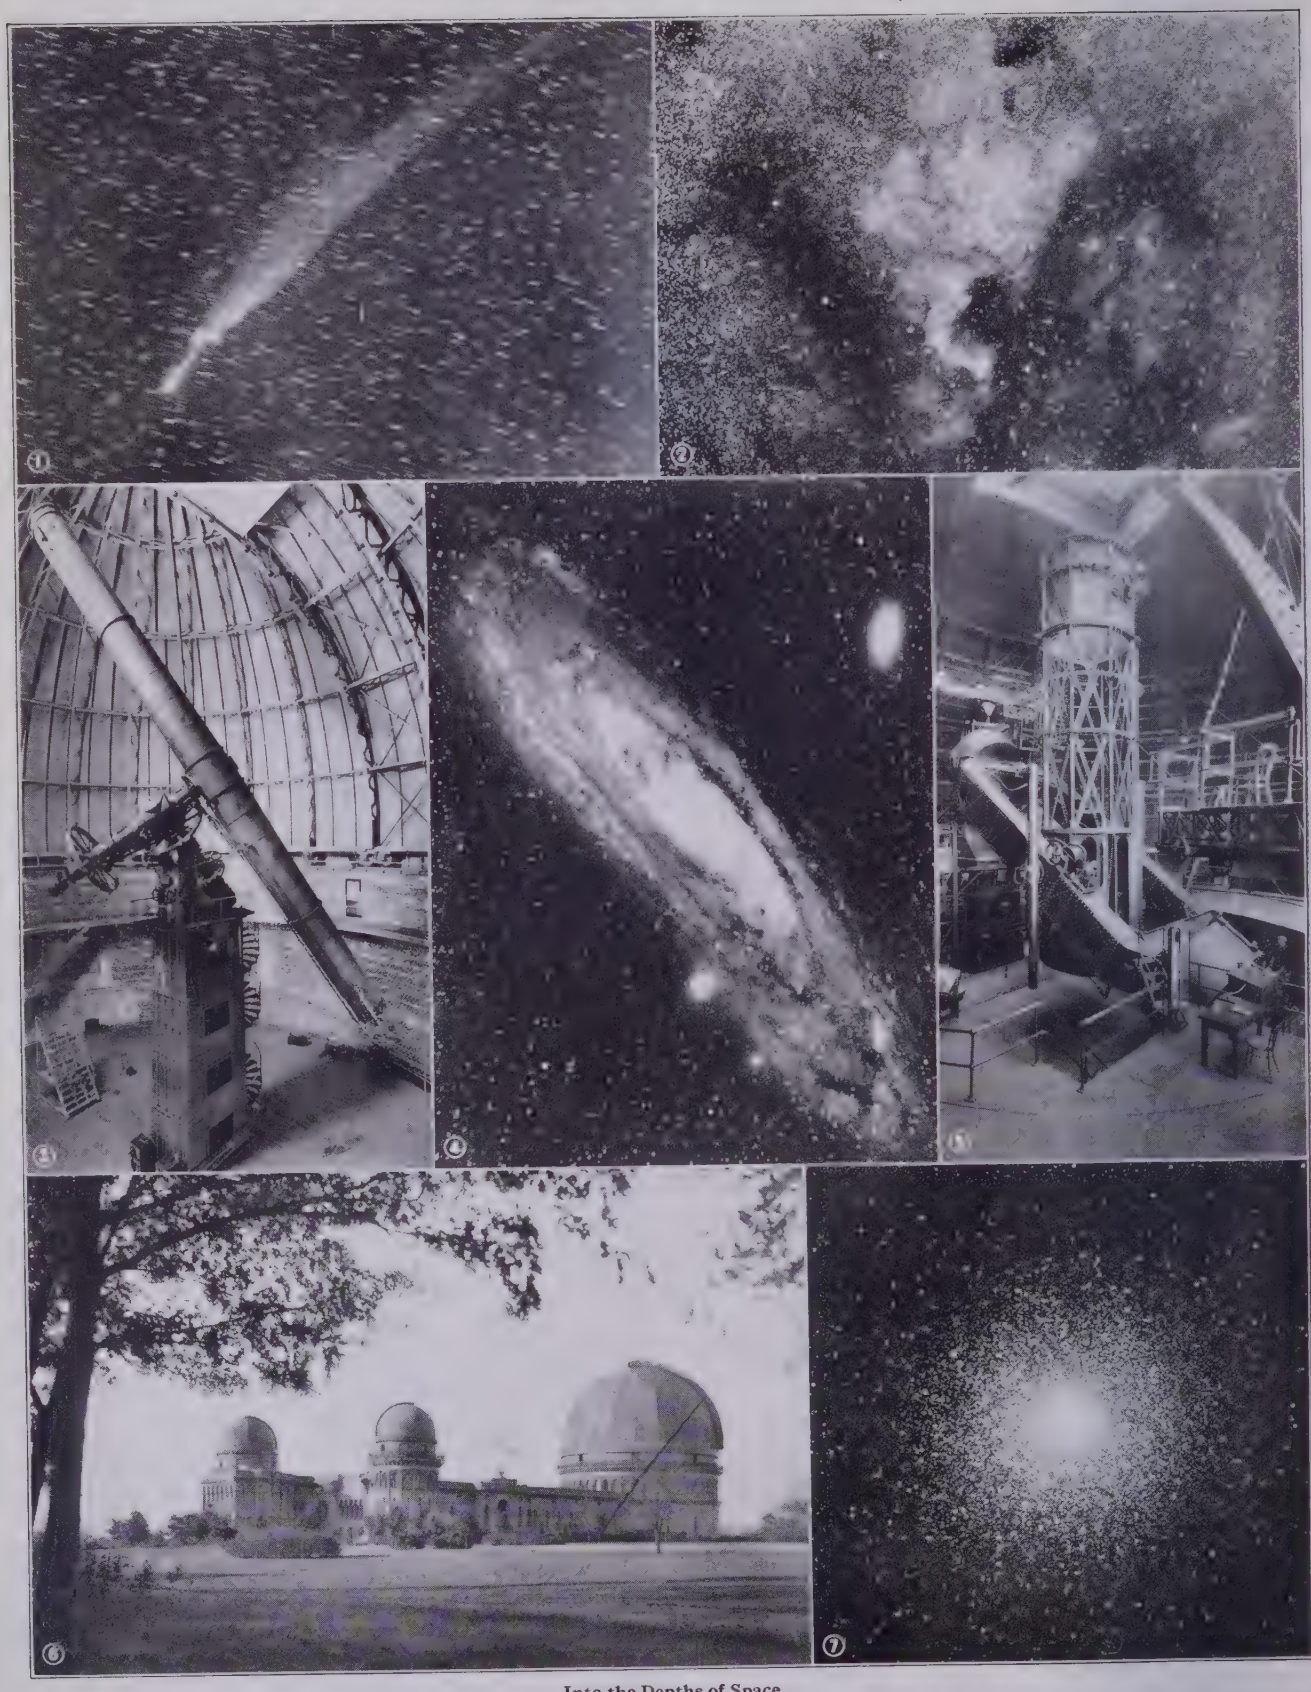
Early in 1930 a still more distant planet was discovered by the astronomers at the Lowell Observatory, Flagstaff, Arizona. The circumstances leading to this discovery are not unlike those which lead to the discovery of Neptune. A keen analysis (*Lowell Observatory Memoirs*, Vol. I, No. 1, "A Trans-Neptunian Planet" [1914]) by the late Professor Percival Lowell of the unaccounted for discrepancies in the motion of Uranus, pointed the way to an unknown planet at a distance about thirty-nine astronomical units, with mass 1/50,000 that of the Sun, in longitude which would put it, in July 1914, if it were near the ecliptic, in one of two alternative positions, either in the eastern edge of the constellation of Taurus, or about 180 degrees from this. The Flagstaff observers had begun the search for this planet before the publication mentioned above and have carried it on until the discovery in January, 1930. Great credit is due to Percival Lowell for his masterful mathematical treatment and to the staff of astronomers at the Lowell Observatory, principally C. O. Lampland, V. M. and E. C. Slipher for their persistent, ingenious, confident observing. C. W. Tombaugh, assistant on the staff, was the first person to note on the photographic plate the object which appears to be a new planet. It has been named Pluto.



Comets and Meteors. Besides the planets with their satellites, and the asteroids, the Sun holds under its gravitational control great numbers of comets and meteors. *Comets* are bodies usually of great size but very small mass, which revolve about the Sun in elliptic or parabolic orbits and, as they move, change shape and dimensions. They shine partly by light reflected from the Sun, and partly by their own light. Most of them are faint objects, visible only with a telescope. When a comet is bright enough to be seen with the naked eye, it looks like a bright star surrounded by a hazy light which may or may not stretch out into a tail. Rare comets —of brightness equal to or surpassing Venus, and visible by day — have been known. Halley's comet, in its 1910 appearance, was a brilliant spectacle. This comet has a period of 75.5 years, and is due to return next in 1985 or 1986. It is the first comet for which an elliptic orbit was computed. Of the comets whose periods have thus far been determined, the intervals between successive returns range from 3.3 to over 1000 years.

The swiftly moving points or streaks of light which on any clear evening may be seen to shine for a second or two and then vanish, and which we call *shooting stars*, are really not stars at all. They are tiny bodies of stone or metal. They move through space with extremely high velocities, and when they strike our atmosphere the energy of their rapid motion is converted into heat and they shine until consumed. One can see several of these *meteors* in an hour on any clear night by merely watching some part of the sky. They are of different colors—white, bluish, green, yellow, and reddish—and sometimes are as bright as the full Moon. Most meteors are very small in size and mass, but occasionally one is large enough and massive enough to fall to the ground before it is consumed. Meteors which get through to the Earth's surface are called *meteorites*. Collections of them may be seen in museums. The largest one known, weighing thirty-six tons, was brought from Greenland by Captain Peary, and is now on exhibition in the Museum of Natural History in New York City. Meteors

The Essential Facts About the Planets



NAME	SYMBOL	DISTANCE FROM SUN (A.U.)	PERIOD OF REVOLUTION	DIAMETER IN MILES	MASS	ROTATION PERIOD	DENSITY	NUMBER OF SATELLITES
Mercury	☿	0.39	88 days	3,000	0.05	88 days*	4.5	None

Sun, Moon and Planets

1. Sun, showing distribution of calcium in solar atmosphere. 2. Sun, showing hydrogen. Both 1 and 2 photographed at Mt. Wilson Observatory, July 22, 1906. 3. Mars, photographed at Yerkes Observatory. 4. The Moon, northern portion at last quarter, photographed at Mt. Wilson with one-hundred-inch reflector, September 15, 1919. 5. Saturn, photographed at Mt. Wilson with sixty-inch reflector. 6. Jupiter, photographed at Mt. Wilson with one-hundred-inch reflector; Ganymede, a satellite, is seen at lower left of planet, and its shadow is seen on the disk.

Into the Depths of Space

1. Morehouse Comet (photographed at Yerkes Observatory, October 15, 1909). During the long exposure the telescope is guided to follow the comet and the star images appear as "trails." 2. North American Nebula (Yerkes) in the Milky Way. 3. Yerkes forty-inch refracting telescope. 4. Andromeda Nebula (Yerkes), a great island universe. 5. Mt. Wilson Observatory, one-hundred-inch reflecting telescope. 6. Yerkes Observatory. 7. Great Star Cluster in Hercules, photographed at Mt. Wilson with sixty-inch reflector, exposure eleven hours.

are probably the remains of disintegrated comets; for many of them are known to travel about the Sun in orbits previously followed by a comet. If the meteors are well scattered along the orbit, we see a meteor shower each year when the Earth, in its orbit, crosses their orbit. Such swarms account for the fact that on certain dates of the year there are sure to be meteor showers from certain constellations. If, however, the meteors are bunched in the orbit, showers will occur only in such years as the Earth and clustered meteors arrive at the orbital intersections together.

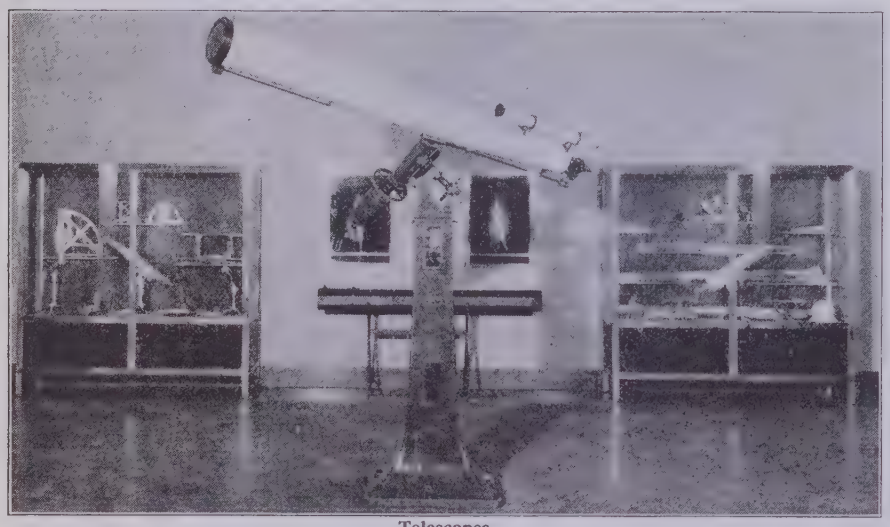
Cosmogony. Various ideas have been advanced from age to age in the endeavor to account for the origin of the solar system. An acceptable theory must account for such facts as these: that the planets all revolve about the Sun in the same direction, in orbits that are nearly circular and in nearly the same plane; and that the Sun and the planets, so far as is definitely indicated, rotate on their axes in the same direction. The satellites, for the most part, revolve about their primaries in the same direction as the planets revolve about the Sun. In this explanation, the *nebular hypothesis* of Laplace held the field for a full century, but now it has been greatly modified or wholly abandoned. It assumed that at one time a large, slowly rotating, nebulous mass, in cooling, gradually contracted. A law of mechanics requires that if a rotating body contracts, it must spin faster. The process of contraction and more rapid spinning continued until the centrifugal force equalled the gravitational attraction, and a ring of material was left behind. This process was repeated until there were several revolving rings. The material comprising each ring somehow collected into a single body, a planet; and the central mass condensed to form the Sun. Modern theories assume the approach of another star to our Sun, with resulting partial disruption and the strewing of debris in the plane of the star's motion as it and the Sun swung about each other. Some of this material fell back into the parent body. The remainder took up orbital motion in the direction of the motion of the other star. Naturally, there would be condensations in this material and these formed the nuclei about which the aggregations took place which ultimately became the planets. A somewhat similar process, secondary in character, would account for the satellites. This explanation, first enunciated by Chamberlin and Moulton, and called the *planetesimal hypothesis*, accounts in a satisfactory way for the items of regularity which demand orderly development of the planetary system according to law.

THE SIDEREAL SYSTEM

Stars. If it were physically possible for an airplane to travel indefinitely into space, it would take one going at a speed of 100 miles per hour, 106 years to reach the Sun, our star. At the same speed, 29,000,000 years would be required to reach the next nearest star. Seen from that star, our Sun would look like one of the brighter stars; but no telescope yet constructed would be able to show the Earth, nor even the giant planet Jupiter. More than half the stars which we see are a hundred times as far away as this nearest one, and the farther ones which telescopes reveal are thousands of times as remote. Only comets and meteors occupy the vast space which surrounds our planetary system.

It is only when we consider the enormous distances of the stars that we can think of these glittering points of light as bodies of the same nature as our Sun. Many of them are larger and hotter than our Sun; some are smaller and cooler. Within the last one hundred years, by use of the spectroscope, a great deal has been learned about the constitution of the stars, their temperatures, and the speeds at which they are moving toward or from us. Indeed, as early as the seventeenth century, Newton had established this fact by another means. From the theory of gravitation he showed that the stars must be hundreds of times as far away as Saturn, for otherwise they would either fall into the Sun or describe orbits about it. At such great distances they could not shine by reflected sunlight, as do the planets.

The stars vary in color, according to their spectra. They are red, yellow, blue or white. The red stars are either young giants or old dwarfs. Yellow stars are either youthful or middle-aged. The blue and white stars are the hottest, and average twice the size of our Sun, which is a middle-aged yellow star, past its prime. It will be smaller when it becomes a dwarf red star, and after that it will perhaps cease to shine at all. But this will be countless ages hence. Giant red stars, like Betelgeuse, Antares and Aldebaran, are 200 to 300 times as large as our Sun. It will be seen that astronomers regard the stars as in a process of evolution, and place them in sequence according to their spectral characteristics. The various steps in the sequence correspond with stages of development. Of course the process is too slow to permit any view of the transitions; but, as one may judge of the development of human beings from studying the characteristics of children, young people and elderly ones, so from the detailed study of stellar spectra arises the idea of the evolution of stars.



When we look up at the stars they seem to be fixed at random on the inside of a large hemisphere. Although their distances have very great range, yet in describing the position of one star with respect to another, we say they are near together if they appear in about the same direction, and far apart if their directions are quite divergent. Therefore, since their separation is only a matter of direction, it must be given in angle—degrees, minutes and seconds. A ten-cent piece held at arm's length is a rough measure for one degree. The Sun and the Moon are each about a half degree in angular diameter. It is well, also, to know angular distances between certain bright stars, to use as yardsticks in the sky; thus, the distance between Alpha and Beta Ursae Majoris, the Pointers, is five degrees.

If we give thought to the arrangement of the stars, the brighter ones naturally fall into outlines and groupings that make up star pictures. We do not all see the same pictures, just as we do not see the same pictures in cloud formations. In olden times the shepherds, while guarding their flocks at night, traced out star pictures of animals and monsters, giants and heroes. They gave names to them and made up tales about them. Most of these names are drawn from Greek or Roman mythology. Some go back even farther. Forty-eight such star groups, or *constellations*, were included in Ptolemy's *Almagest* of the second century. These include practically all that can be seen in north latitude about forty degrees. Since 1600 A.D., forty more constellations have been named; most of these are seen only in the southern skies or are made up of the less conspicuous stars. So now, eighty-eight constellations map out the entire sky that can be seen in any latitude at any time on any night. The boundaries between them are imaginary lines, just as are some of the boundaries of countries. The early constellation names, and the legends connected with them, have come down to us through the centuries. Realization of their antiquity adds to the interest in learning them. The naked-eye stars are designated by the letters of the Greek alphabet coupled with the constellation name, usually in order of brightness, though there are some exceptions. If there are more stars in a constellation than there are letters in the Greek alphabet, Roman letters are used; numbers afford an alternative method. About sixty of the brighter stars have proper names, too. For example, the brightest star in the constellation Taurus is Aldebaran, and it is Alpha of Taurus, written Alpha Tauri (the genitive case of the constellation name is always used).

To one living at the North Pole, the Pole Star (Polaris, or Alpha Ursae Minoris) would always be directly overhead. His horizon would coincide with the equator, and as the Earth rotates on its axis from west to east, the stars would appear to travel from east to west in paths parallel to the horizon. Half of the stars would always be above the horizon for him; half of them he would never see. At the South Pole the same conditions would prevail, except that the two hemispheres would be reversed. To one living on the equator the stars rise and set at right angles to the horizon, and all stars are visible in the evening at some time of the year. For those living in latitudes between zero degrees and ninety degrees north or south, some stars are never seen, others are always above the horizon, and the rest rise in the east and set in the west obliquely to the horizon. Since the Earth travels once around the Sun in a year, the Sun appears to us to have made the complete circuit of the heavens with relation to the stars. It moves eastward about a degree a day, or thirty degrees a month, that is, through one sign of the Zodiac. For this reason we do not see the same constellations in the same part of the sky at the same hour the whole year around. There is a gradual shifting, so that one set of constellations is left in the sky at sunset at one time of the year, and six months later those of the opposite part will have replaced them. It will be clear that by the Earth's rotation on its axis once in twenty-four hours, our position with relation to the stars is changed as much in two hours on any one night as it is changed for the same hour of night by a month's revolution about the Sun. So the star pictures that one sees depend upon the

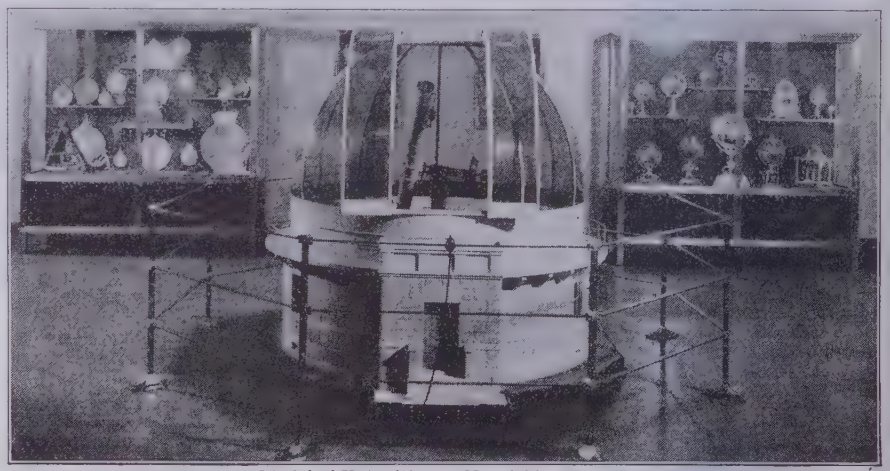
latitude in which he is viewing the heavens, the time of year, and the time of night.

At a glance we will be able to pick out a dozen or more stars that are outstandingly brighter than the others, and we will note that there are fainter ones all the way down the scale to those which we can barely see.

Telescopes

In the foreground, mounted on a pedestal, is a modern eight-inch refractor. Behind it is an ancient telescope of Sir William Herschel. Above are two transparencies (photographs) of celestial objects. In the two cases are numerous early types of telescopes and other ancient astronomical apparatus. The view is in the Museum of the Adler Planetarium, Chicago.

The brightness of a star is called its *magnitude*, and depends upon three things—its size, distance and temperature. Stars just visible to the naked eye are of the sixth magnitude. Fifth magnitude stars are two and one-half times as bright; fourth magnitude stars, six times as bright; third magnitude, sixteen times; second magnitude, forty times; first magnitude, one hundred times. This magnitude scale is continued upward to zero and minus magnitudes, and downward to the faintest stars visible in the largest telescope, the greater magnitude numerically indicating the fainter star; and any two stars which differ by five magnitudes differ a hundredfold in brightness. There are only twelve first magnitude stars in the whole sky; there are twenty of magnitude 1.5 or brighter; forty of the second magnitude; 200 of the third magnitude; 500 of the fourth; 1,500 of the fifth; and 5,000 to 6,000 of the sixth or brighter.



So the stars are by no means numberless, as we are likely to think. Subtracting from the 5,000 naked-eye stars those that are below the horizon and those that are invisible because of the haze near the horizon, only about 2,000 to 2,500 are visible at any one time. With a field glass, 50,000 can be seen; with a two-inch telescope, about 300,000; with the 18½-inch refractor of the Dearborn Observatory, 40,000,000; with the 40-inch of the Yerkes Observatory, 140,000,000; and with the 100-inch reflector of the Mt. Wilson Observatory, about 1,000,000,000. The total number of stars in our sidereal system is from 30,000,000,000 to 40,000,000,000. This limit is derived by determining the number of stars of successively fainter magnitudes visible on photographs of long exposure.

A casual view of the sky shows that the stars are not uniformly distributed, that there are regions with few stars, and others with many. More careful examination shows that the number of stars in any unit of area in the sky increases as approach is made to that broad hazy belt of misty light around the sky, known as the *Milky Way*.

If the Milky Way is examined with the telescope, or better, photographed with a portrait lens, it is shown to be made up of myriads of stars. We conceive our sidereal system to be roughly the shape of a grindstone or a thin watch, with the solar system somewhere near the center. If we look toward the edge of the system we see many stars and this produces in the sky the appearance which we call the Milky Way. If we look toward the faces we see comparatively few stars. Research indicates a diameter for our galaxy of between 200,000 and 300,000 light years, while the thickness is about one-tenth of this figure.

It is possible to gain an idea of the shape of our sidereal system, and of the distribution of the stars within it from counts of the stars in the different regions, without having any knowledge of the dimensions of the system. In order to know the scale of it, it is necessary that we be able to solve the fundamental problem of the determination of stellar distances. Only the direct, trigonometric method is explained here. There are other indirect, and perhaps less restricted, methods.

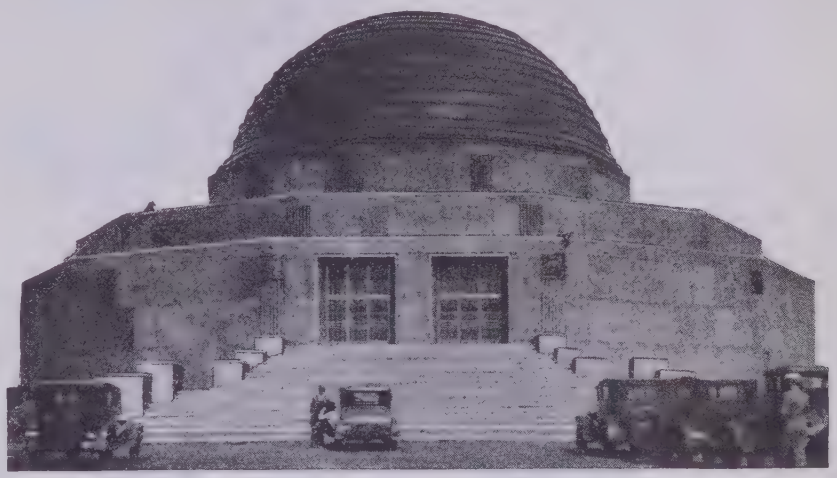
If one sways back and forth from right to left, looking at some nearby object the while, it will be seen that, as the body sways to the right, the nearby object will appear to move to the left when compared with distant objects in the background; and when the body sways to the left, the opposite will be the case. This apparent displacement of the nearby object is called *parallax*, and the principle is employed in determining the distances of the nearer stars. Instead of the body moving back and forth, we have the Earth moving about its yearly orbit. When the Earth is on one side of the orbit, a star will appear in a certain direction with respect to the more distant stars in the background. Six months later the nearer star will appear slightly displaced from the original position. The nearer the star the greater will be its parallax. For the nearest star, Alpha Centauri, the parallax is 0.″75. The angular value of this displacement, coupled with the known diameter of the Earth's orbit, furnishes the means for determining the distance to the star in much the same way that one determines the distance to an inaccessible object on the Earth by laying down a carefully measured base line and measuring the angular position of the distant object from the two ends of it. The presence of this parallactic displacement has been cited as a proof of the Earth's orbital motion. The problem of determination of stellar parallax (although simple enough in conception), on account of the minuteness of the displacement, is one of the most difficult problems of practical astronomy.

Model of United States Naval Observatory

This view in the Museum of the Adler Planetarium, Chicago, shows a model of the United States Naval Observatory in Washington. Like the original, the model has a movable dome, movable floor and movable telescope. In the case at the left are astrolabes, ancient astronomical instruments. In the case at the right is a collection of armillary spheres.

The remoteness of the stars makes it necessary to use a unit of distance larger

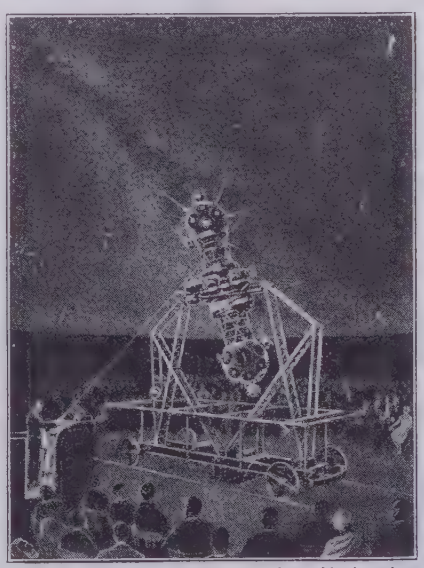
even than the astronomical unit, in order to avoid extremely large figures. The *light year* is the distance light travels in a year, at a speed of 186,000 miles a second. The star nearest to our solar system (Alpha Centauri) is 4.3 light years away. It should be noted that our Sun is eight light minutes distant. The average distance of a first magnitude star is 36.5 light years; of a second magnitude, 58 light years; of a third magnitude, 92 light years. Of the bright stars in the northern sky, it happens that the brightest, Sirius, is also the nearest; we see the light which left it a little less than nine years ago. Altair is sixteen light years away; Vega, twenty-seven. The giant star Antares is 250 light years away. To be as bright as it is, it must, of course, be very large: the orbit of Mars could be put inside of it.



The stars appear to us to be fixed, but this is only because they are so far away. Through the centuries there has been slight change in the apparent arrangement, but actually they are moving through space in all directions at speeds much greater than cannon shot. From observations of the motions of the stars it is found that our star, the Sun, is moving through space toward a point in the constellation of Hercules at a speed of about twelve miles a second.

Some stars change in brightness from time to time. These are called *variable stars*. The outstanding naked-eye variables are Mira, or Omicron Ceti; Algol, or Beta Persei; Delta Cephei, and Betelgeuse, or Alpha Orionis. Over 5,000 variables are known at the present time, and more are being discovered each year. They are classified according to the cause or character of the variation in light, and according to the length of period. The observation of variable stars is one field in which amateur astronomers may profitably work, cooperating with the great observatories.

If one with a keen eye looks closely at some of the stars, he will see that there are two stars instead of one. Many thousands of close pairs may be seen in a telescope. Some of them appear double only because two stars are nearly in the same line, though they are really far apart in space, while others are actually close together and held by their mutual gravitation. Many of them show that they are moving along together or that they are in orbital motion about their center of mass. Stars which show orbital motion are known as *binary stars*. Only for binaries is it possible to find the mass.



Star Clusters. Searching the sky with a field glass or telescope, one sees here and there hazy patches of light. Higher optical power in some cases resolves these hazy patches into thousands of stars grouped more or less compactly into a spherical shape. They are called *globular clusters*. About a hundred such are known, the diameters of which are all approximately the same, five hundred light years. They are at enormous distances, ranging from 20,000 to 200,000 light years, on the outskirts of our star system.

Nebulae. The hazy diffuse patches in the sky which can not be resolved into stars by large telescopes are called *nebulae*. Many of them are very beautiful objects when viewed with the telescope or as shown on photographs. Nebulae are classified according to form, constitution or distribution. Under the first heading, nebulae are either irregular or chaotic, planetary, ring form or spirals. According to distribution with reference to our sidereal system, or galaxy, they are either *galactic* or *extra-galactic*. These classifications are not mutually exclusive, for the terms *spiral nebulae* and *extra-galactic nebulae* are well nigh synonymous.

The Adler Planetarium and Astronomical Museum, Chicago

The non-galactic, or the spiral nebulae, are by far the most numerous, running into the tens of thousands. The region of the North American Nebula (illustrated) shows not only the star clouds of the Milky Way but also the diffuse galactic nebulous matter involved. The Andromeda Nebula, shown here, is the most remarkable of the extra-galactic spiral nebulae. Studies of this vast system, and of others like it, have led to a new conception of our cosmos. From a study of their spectra, they appear to be stellar in character; indeed, they may be partially resolved into stars, and their distances are found to be such that they are beyond the limit of our sidereal system and therefore must be regarded as distinct stellar systems, which have come to be called *Island Universes*. We must therefore think of our galaxy, enormous as it is, as but one—though perhaps the most magnificent—of a great supergalaxy.

Projecting the Stars

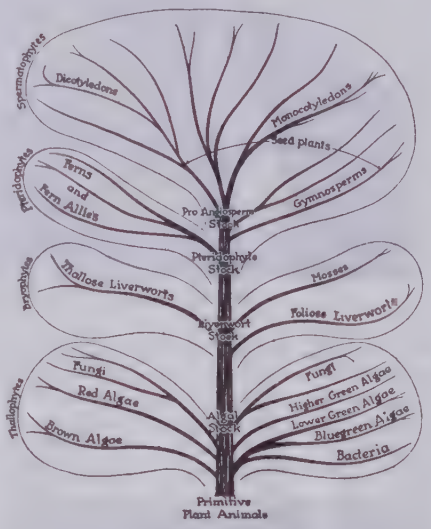
Showing the intricate projector in a planetarium throwing the stars in their motion on the dome which serves as a screen. The Sun and Moon and the planets likewise appear. The lecturer uses an arrow of light to point out the many celestial bodies.

Planetariums

In recent years there has been devised an instrument, known as a *planetarium*, which may accomplish much for popular instruction in astronomy. Several have been erected in Germany, where the instrument was devised, and outside of Germany they have now (1931) been erected in Vienna, Moscow, Rome, Milan, Chicago and Stockholm. By means of a complex projector, the representation of the entire heavens may be thrown on the interior of a large concave hemispherical dome. This artificially produced sky is startlingly real. The instrument may be set to depict the heavens of any terrestrial latitude and for any time; it may be driven to show the apparent celestial motions, such as the diurnal motion, and even the changes due to precession. The Moon, Sun and planets are shown by means of special projectors, and their apparently complex motions are faithfully reproduced. Various speeds may be used, so that the diurnal motions of the heavens, and even the annual motions, may be compressed into a few seconds. This acceleration gives a realization of the annual course of the Sun among the stars, the planetary orbits, and the intricate apparent motions of the planets in them. In no other manner can these phenomena be so interestingly seen and so easily understood.

In the building which houses the Chicago planetarium there is also an astronomical museum. In this are shown instruments and models to demonstrate the modern practice of observing; instruments to show laws of optics, spectroscopy, and dynamics; a series of astronomical photographs in the form of transparencies; and a superb collection of antique astronomical instruments.

BOTANY



OUR shade trees, lawn grasses, the flowers and shrubs of our gardens, and the crops and vegetation of the fields are recognized as plants without the exercise of imagination. When it is pointed out, however, that a bottle of souring milk, a batch of yeast-risen bread, or even a handful of rich garden earth each represents a vast population of microscopic plants, the problems of knowing the plants about us either by name, form or activity begins to assume large proportions.

Plants are not all "flowers," not all visible to the unaided eye, not all green. Moreover, taking consideration of plants that grade from the huge to the microscopic, from the complex to the very simple, and being warned that diversity of form is perhaps no less marked than the variety exhibited in their structure and living processes or products, we may be better prepared to understand how vast is the field of science that includes all phases of knowledge respecting plants. With increasing knowledge of form and activity, it becomes more difficult to frame briefly a definition of a plant. Some of the lower plants are not readily distinguished from lower animals; some are claimed by the zoölogist as well as by the botanist. This, indeed, might be expected; for many facts point to certain generalized types as primitive organisms—not necessarily either plant or animal—yet *organisms*.

It is not possible to give a definition of a plant that is concise and at the same time inclusive of all kinds of plants, without having to make many exceptions. Consequently the following is merely a practical or proximate form of a definition: A plant is a living organism (a) either simple or complex in structure, (b) generally possessing green pigment (*chlorophyll*), (c) absorbing its nutrients in solution, and (d) commonly non-motile or permanently fixed in position. It will be seen that, in general, characters (b), (c) and (d) distinguish the plant from the animal, because the latter ordinarily contains no chlorophyll, ingests its food, and is characteristically motile. Other distinguishing features might be considered in a more detailed treatment of differences.

The Cell. The simpler or lower plants, such as the pond scums, differ very greatly in appearance and size from the higher or seed plants; but all plants are composed of units, called *cells*. The simplest green water plant (an *alga*) consists of a single cell; a maple tree is an enormous complex of cells. Every cell consists of a unit mass of living substance (*protoplasm*) surrounded by a box-like cell wall. This may seem very simple, but living protoplasm is almost inconceivably complex if we think of it in terms of what it can do; that is, in terms of its activities. Protoplasm is definitely organized into parts readily visible under the microscope. Most conspicuous and important are (a) the *cytoplasm*, constituting the major part of the viscid contents, and (b) the *nucleus*, the denser spherical mass of protoplasm, always surrounded by cytoplasm and commonly exhibiting a smaller refractive mass known as the *nucleole*. In mature plant cells, the cytoplasm occupies primarily a layer just within the cell wall and there is usually a large central *vacuole* of cell sap. However, strands of protoplasm may extend from one side of the cell to the other across the vacuole. In the green cell there are differentiated in the layer of cytoplasm special protoplasmic bodies called *plastids*, and these contain the green pigment, chlorophyll. Food materials are also frequently stored in the protoplasm or in the vacuoles. Very young cells are usually richer in protoplasm, and the vacuole is of less extent.

Throughout this discussion it will be necessary to refer to the work of cells, whether in dealing with one-celled organisms or with complex organisms, whether in thinking of them as acting individually (as in the solution-absorbing root-hair cells) or as components of a mass of cells (tissue) or of an organ (a root tip, for example, boring its way through the soil).

The Botany Tree

This diagram shows relationships and development in the plant kingdom. It will be helpful to study this diagram in connection with the accompanying text.

The Subdivisions of Botanical Science. In modern times when the vastness of the field of botany or plant sciences has come to be more generally, but often still rather vaguely, understood, one frequently hears this question asked: What does botany include? Departing from a formal definition as briefly outlined in a previous paragraph, the various recognized subdivisions of the science may be noted. As a matter of fact, these are provisional divisions of knowledge, and are clearly recognized as overlapping; yet each one is suggestive of a more or less distinctive point of view in the presentation of material for academic purposes or for general information.

The following divisions are generally emphasized: classification (*taxonomy*), the grouping of related forms of organisms for purposes of systematization; description of form (*morphology*); structure, especially in the development of relationship (*anatomy*); an intimate study of tissues (*histology*); special characteristics of cells (*cytology*); the study of plant remains and relationships as exemplified through fossils in the rocks and through preserved material in soil strata (*paleobotany*); functions, behavior and the physics and chemistry of life processes (*physiology*); relationship and behavior of vegetation in respect to habitat and environment (*ecology*); the basis and facts of heredity (*genetics*); relationships of plants as to origin, in point of time (*phylogeny*); the special forms and activities of bacteria (*bacteriology*), of algae (*algology*), of fungi (*mycology*), of lichens (*lichenology*), of moss-like plants (*bryology*); the treatment of microscopic life (*microbiology*); special fermentative processes (*zymology*); the relation of plants to disease (*pathology*); the study of plants and plant products as therapeutic agents (*pharmacognosy* and *pharmaceutical botany*); and further applications in respect to such phases of general agriculture as field crops (*agronomy*), garden and flower culture (*horticulture*), tree culture and wood uses (*forestry*).

It is practicable to give further and more detailed attention to only a few of the above subdivisions.

CLASSIFICATION OR TAXONOMY

The classification of plants and animals into groups of related organisms is the function of taxonomy (from the Greek words meaning "law" and "arrangement"). Plants of diverse sorts exist; those that seem to be related because of similarities in form and structure are assigned to a definite group, and smaller groups are associated into larger divisions, still with some common characteristics. Group names are given in the efforts of scientists to systematize our knowledge. Some organisms do not fit well into any group, or perhaps they fit indifferently into several groups. In nature, all types and degrees of diversity have developed. Nature is not concerned with the maintenance of groups. Classification, then, is not fixed; men's opinions may differ as to the value of the characters used in classification, or organisms may be shifted from one group to another as our knowledge of structure and life history increases. Nevertheless, the idea of classification is to present a natural system of relationship, and, to paraphrase an expression of Asa Gray, the great American botanist of the nineteenth century: The whole should form, as it were, a great map in which the larger divisions or classes might answer to countries, the families and orders to states or provinces, and the individual species to hamlets, villages and towns.

The Thallophytes. The thallophytes, or class *Thallophyta*, are plants possessing neither stems nor leaves. They may consist of a single cell of various forms, or they may be multicellular, and of most diverse appearance. The plant body is a *thallus*. Two divisions are recognized, algae and fungi. Algae are usually "independent," possessing chlorophyll (leaf green), and accordingly able to make the organic food material required. Fungi possess no chlorophyll and are dependent upon an outside source of carbon-furnishing food, such as the carbohydrates.

Algae. Algae are primarily water plants,

BOTANY—SELECTED TYPES OF FLORAL STRUCTURE, FLOWERING SHOOTS AND FERN PROTHALLUS

1. Composites: (a) head with rays, (b) ray flower, (c) disk flower, (d) head of tubular flowers.
2. Gagea: flower.
3. Maple: (a) pistillate, (b) staminate flower, (c) fruit.
4. Clove: shoot, flower section, fruit.
5. Lamium: two-lipped flower, side and front.
6. Orobanche: flower section.
7. Pepper: flower, fruit.
8. Oenothera: flower section.
9. Aralia: flower.
10. Cornus: flower.
11. Clover: habit, (a) flower, (b) fruit, (c) seed.
12. Beech: (2) staminate, (3) pistillate flowers.
13. Sage: flower and section.
14. Oak: (2) staminate, (3) pistillate flower, (4) acorn.
15. Peach: flower section.
16. Saxifrage: flowers.
17. Ash: apetalous flowers.
18. Grape: shoot, opening of flower.
19. Gentian: flower section.
20. Cinchona: flower, fruit.
21. Carrot: shoot, flower, fruit.
22. Fern prothallus.
23. Alfalfa: shoot, (a) flower, (c) seed.

BOTANY—HABIT SKETCHES AND FLORAL ARRANGEMENTS

Showing habit sketches and floral arrangements of selected seed plants, also habit sketch of the field horsetail.

1. Cotton: shoot, boll, seed.
2. Linden: flower section.
3. Tamarix: flower section.
4. Morning glory: habit, flower section, fruit, seed.
5. Willow: (4, 5, 6, 7, 8, 9, 10) flowers, seed.
6. Dammar-pine: leaves, cone, scale.
7. Magnolia: flower section.
8. Field horsetail: plant form.
9. Arnica: flowering shoot.
10. Thistle: (a, b, c, d) habit, flowers, pappus.
11. Flax: habit, fruit, seed.
12. Monotropa: flower section.
13. Poppy: flower section.
14. Birch: flowers in catkins.
15. Melon: flower section.
16. Buttercup: flower section, pistils, stamens, ovules.

many of the fresh water forms being known as pond scums, while among the marine population are red sea weeds, kelps and others. Some species grow attached, and others constitute much of the floating life of aquatic habitats. The smaller forms especially may constitute an important factor in the food of the animal life of waters, even of the fish. Reproduction may be effected by simple fission or by non-sexual spores which may be motile or non-motile. Various types of fusion cells, or *gametes*, may occur. Four main classes require consideration.

Green Algae. Algae in which the pigment chlorophyll is conspicuous are more numerous than all others combined; about 10,000 species are recognized. The pigment is contained in an organized cell structure known as the *chromatophore* or *chloroplast*. There are several families or major divisions of the green algae, differing one from another in the form and complexity of the thallus and in their sequence of development, or life history. The more primitive forms are unicellular, and certain of these (for example, *Chlamydomonas*) possess whip-like motile organs (*cilia*) when in the active vegetative state. Gametes occur, but reproduction is primarily by simple fission—a parent cell becoming quiescent and dividing into two. In this organism, therefore, as also in such non-motile algae as *Protococcus*, death of the parent cell does not occur, so that any cell may be immortal. *Protococcus* may occur in temperate climates, on shaded sides of trees and in other moist situations. Colony forms of ciliated algae are particularly interesting, as in the free-floating *Volvox*.

Diatoms, peculiar unicellular algae with their cell walls impregnated with silica, may grow in such quantity that upon the decay of the cells a diatomaceous deposit occurs. Geologically such deposits are of practical value, constituting the well-known abrasive material, diatomaceous earth, also known by various trade names.

Filamentous forms of the green algae are numerous; these are the typical pond scums. Among these the methods of reproduction are diverse. Green algae of various types also occur in the sea. Of special interest as to form is *Ulva*, the sea lettuce, consisting of colonies of cells forming broad ribbons or leaf-like structures.

Blue Green Algae. These algae, the *Myxophyceae*, owe their common name to the occurrence of a blue pigment along with the chlorophyll of the cell. They may occur as single cells, but colony-forming species are more commonly observed. Colonial characteristics are diverse—filaments, chains and other forms. A gelatinous sheath or extensive jelly may inclose the colony. In stagnant water the decay of blue greens may give disagreeable odors. These are simple algae apparently with less organization of the cell than in any other algal group. Reproduction is by simple fission of the cell.

Brown Algae. A high degree of complexity and differentiation of structure is exhibited by many of the brown algae. They are almost exclusively marine. The rockweed is a common type. This alga grows upon rocks between high and low tide. Species of *Laminaria*, or kelp (also called "devil's apron"), occur in deeper, colder waters; and on the Pacific coast a giant kelp, *Nereocystis*, often grows to exceed one hundred feet in a season. The sea palm (*Postelsia*), properly named from its growth habit, is a proud occupant of the rocks within the tidal levels. Chlorophyll is present in these algae, but is masked by the occurrence of another pigment, golden brown in color, as seen in the plastid or chromatophore. Reproduction in the brown algae is characterized by gamete production. In *Fucus*, the gametes are strongly differentiated; relatively large egg cells are liberated from one sex organ (*oögonium*) and minute *antherozoids* from the *antherids* are set free in large numbers.

Red Algae. Members of the group *Rhodophyceae* are generally red in color and typically marine. While not the largest in size, they are the most attractive algae in color and in variety of form. They may be filamentous, more massive and highly differentiated; or they may be membranous. Here, also, the chlorophyll is masked by a plastid pigment. The reds often frequent deep waters, and in regions of extended sunshine they have been found at depths exceeding 300 feet. The red algae are not closely related to the preceding groups. Although characterized by the production of gametes, their cells are non-motile, and the mechanism effecting fusion as well as the development of spores, is peculiar to this group.

Fungi. The second great division of the thallophytes, the fungi, are commonly filamentous in the vegetative condition, and are distinguishable from the algae primarily by the absence of chlorophyll. Practically speaking, they occur wherever organic matter exists, since some one or more species may inhabit any dead or non-living material, and many species attack living tissues, especially those of seed plants. The chief classes of fungi are the *Phycomycetes*, *Ascomycetes* and *Basidiomycetes;* but broadly limited they may be said to include also the bacteria and the slime molds.

Phycomycetes. These are the algal-like fungi, in the sense that they resemble certain algae, of which they were once supposed to be degenerate forms. Other common names applied to certain groups are water molds, black molds, downy mildews. The typical filament or thread-like growth of a fungus is a *hypha*, and a greatly branched mass or colony of hyphae constitutes a *mycelium*. The filaments of these fungi are ordinarily without cross walls (*siphonaceous*), and there are many nuclei in a hypha (*coenocytic*). Some species of water molds are parasitic, one form causing a disease of fish. The black mold of bread is a common form. The downy mildews are parasitic on seed plants; thus there is a destructive disease-inducing species known as the downy mildew of grape. In general, there are non-sexual spore forms as well as gametic, or sexual, reproduction. Lower *phycomycetes*, possessing no distinct hyphae and no well differentiated cell wall, are sometimes constituted a distinct class.

Ascomycetes. The chief character distinguishing this class is the production, during reproduction, of a spore-sac, or *ascus*, typically containing eight spores. The ascus stage is called the "perfect" stage. It is commonly a sequel to a fusion process. There may be various types of subsidiary, or non-sexual, spore forms. In the major divisions of this group the asci are produced within a fruit body, the *ascocarp* (*apothecium*, *perithecium*). The mycelium possesses cross walls, and the cells have usually but one nucleus. More than 10,000 species are known. They occur in the most diverse situations. The *saprophytic* species, or those inhabiting dead material, are found abundantly upon decaying vegetation and in or on the soil. The blue and green molds of food products belong to this group, as do also a few families of fungi with large and fleshy fruit bodies, such as the edible morels, or sponge mushrooms. Parasitic species are likewise numerous. Such well-known plant diseases as apple scab and rose mildew are examples of the effects produced. The *Ascomycetes* include upward of twenty-five families.

Basidiomycetes. This class of fungi comprises orders and families very diverse both in structure and in habitat, but the different subclasses are supposed to be related through the possession of a *basidium* (a club-shaped cell or cells) which typically bears four spores. Rusts and smuts constitute the main parasitic groups, while other divisions include the vast majority of the fleshy or woody fungi such as the mushrooms of field and forest. Smut fungi are known to the casual observer chiefly through the spore stage. Thus the smut of corn is little more than a mass of spores, yet a mycelium within the tissues produced those spores. Rust fungi exhibit an exceedingly interesting and complicated life history. On the host plant they are characterized ordinarily by the occurrence of rusty spots; actually these are *sori*, or beds of the spores of the fungus. The woods and fields of almost any forested locality will yield hundreds of fungi variously known as mushrooms, fairy wands, brackets, punks, puff balls and so forth. They grow on the soil or on decaying logs and vegetation, and a considerable number cause heartwood or sapwood decays of trees and decay of timber. Among fleshy forms there are edible species and poisonous species (a few of these only); there are those soft in texture and those hard and woody; they vary in size from those that are microscopic to brackets two feet across.

Bacteria. Among the fungi there are usually included the smallest plants known, the *bacteria*. These are sometimes designated "fission fungi" because of their method of division. They seem, however, to constitute an independent group, perhaps related to some of the lower algae. They are so small that they are visible to the unaided eye only when growing in colonies of many hundreds or thousands together. If arranged end to end it would require about 500 of these bacteria of average size to reach across the head of a pin. A study of the bacteria requires a special technique, since for careful examination they must be grown in pure cultures. They are universal in occurrence and are popularly called *germs*. In human and animal diseases they play a chief rôle; likewise they make up much of the life of soil and of open waters. They are the agents of many useful fermentation processes, as in the dairy industry, in vinegar production, and in the retting of flax.

Lichens. These plants constitute another group which does not fit closely into the

scheme of classification given. A lichen consists of a fungus and an alga growing together, probably mutually helpful, to form a dual colony so closely associated that the colonial composite acts as an individual. To a degree the fungus is parasitic upon the alga and holds it captive, but the alga is thus enabled to grow in many places where it could not otherwise exist. Within the lichen the alga multiplies vegetatively, whereas the fungus, in addition, has its characteristic spore reproduction. Lichens grow commonly upon trunks and branches of trees, rocks and soil. Some are thallus-like or flattened, some are moss-like in appearance. The reindeer "moss," a lichen, is typical of the latter group. They are often gray-green in color, very resistant to extreme conditions, and some species form a considerable element in most northern or arctic climates.

The Bryophytes — Moss-like Plants. The mosses and moss-like plants (class *Bryophyta*) constitute a considerable group of green plants higher in the scale of development than the algae. As a class, however, they are much smaller and less complex than seed plants. In general, they are most familiar to us as miniature velvety or feathery growths occupying all sorts of situations—carpeting the ground in many moist or dry places, growing upon rocks, the trunks of trees, and some even in ponds or running water. The parts of the mosses usually visible have an appearance analogous to higher plants; that is, a stem-like axis having numerous leaves. There is, however, no true stem and root such as characterize seed plants. The bryophytes include the true mosses and liverworts, the latter being often flattened or thallus-like (see "Thallophytes"). Mosses propagate by buds or by continued growth (both spoken of as "vegetative" reproduction), but they are typically reproduced by means of simple (one-celled) spores produced in capsules (*sporangia*) that are ultimately raised above the leaves on simple stems called *setae*. The structure of a moss sporangium is so interesting that it will repay close examination.

The conspicuous moss plant originally grows from a bud that forms on another stage of the moss plant; this stage is filamentous and is known as the *protonema* (meaning "first thread"). This protonema develops directly from the germination of the spore, mentioned above. There is a very definite sexual generation and a non-sexual generation in mosses, the proper characterization of which would require more space and study than is practicable in this treatment.

The Pteridophytes—Ferns and Fern Allies. Among the better known groups of the class *Pteridophyta* are the true ferns, quillworts, horsetails or scouring rushes and the club mosses. Ferns are usually unrestricted as to habitat, but we think of them more particularly as growing in moist woods and along shaded streams; yet the bracken, for example, is a common fern of more exposed slopes and roadsides as well as of the borders of the woods. Several species of ferns occur on the sides of rocky cliffs. Scouring rushes are equally diverse in their home requirements—some occurring on dry railroad embankments, others on moist banks and in the shade; but the American club mosses are chiefly shade-loving plants of the forest floor. Those familiar with the decorative ferns of the home and with the ground pine (a club moss) of many northern evergreen forests will regard this class as a rather diverse one. That is true from the standpoint of grosser form (morphology), yet all these groups have much in common.

Ferns are characterized by the possession of stems, roots and leaves, those of temperate climates having stems restricted to underground growth, known as *rhizomes*. The leaves arise from this stem, and growth of the leaf (*frond*) is primarily from the tip. The mature leaf is usually large and complex. The unfolding of this incurved (circinate) tip is engagingly clear and rapid. Moreover, the fern has much in common with the seed plants in the differentiation of special supporting and woody or conducting (vascular) tissues.

While moss-like in general appearance, the club mosses are also comparable with ferns in that they possess stems, leaves and roots; but the stems are largely above ground, and the leaves are small and scale-like. Vascular tissue occurs in this group also.

All groups in this class exhibit what is known as a "sexual generation" (*gametophyte*) in which the vegetative structure is very simple and thallus-like (also called *prothallus*). It is seldom found except in the case of the fern. Here it is more conspicuous and may be found on pots or soil in the greenhouse where ferns are grown, each prothallus consisting of a membranous, heart-shaped green structure, seldom much larger than a baby's finger nail. These structures originate the sexual organs—the eggs and sperms (both gametes). These, after gametic union, produce the larger generation which is the fern or club moss proper. Such fern plants, whatever their forms, have in common the function, ultimately, of spore production; and they constitute the *sporophyte*, or *sporophytic generation*. In the ferns, the spores are borne in small cases, or sporangia, often distributed in sori as dots, rows, or larger masses on the under surfaces of the fronds. Usually these spores are all of the same size, and each consists of a single cell. These spores germinate and give rise to the prothalli.

In the quillworts the spores are of two sizes, and they are produced in sporangia at the bases of the leaves. In the ground pines and club mosses the sporangia occur on leaves (sporophylls) towards the tips of branches, often forming a loose cone. In the ground pine (*Lycopodium*) these spores are alike in appearance (homosporous), whereas in the small club mosses (*Selaginella*) the spores in the two kinds of sporangia are again different in size (heterosporous). These two spore sizes are significant, for the larger one (megaspore) produces the female prothallus (gametophyte), whereas the small spore gives rise to the male gametophyte.

Seed Plants. The complexities of the great groups of seed plants, the highest division in the plant kingdon, are too many to lend themselves readily to brief treatment. Consequently it will be necessary to consider only a few generalized characteristics of this climax group. Spores such as occur in the club mosses are no longer so conspicuous to the casual student; but they occur none the less, and the generation which bears them (sporophyte) is practically the entire plant. Another structure has arisen. This is the *seed*, and it contains an embryo plant. The production of this embryo plant is preceded, of course, by gametic union, or fertilization; but details of the gametophytes must be omitted here.

Seed plants embrace two major divisions, the gymnosperms (with seeds not enclosed) and the angiosperms (with enclosed seeds).

Gymnosperms. Familiar examples of gymnosperms are the pines, spruces and other evergreen trees or shrubs with cone-like fruits, known as the *Coniferae*. In these, the spore-bearing leaves or scales (sporophylls) do not constitute a flower. As the scales of the seed-bearing cones separate, the winged seeds may be seen, a pair under each scale.

The vast forests of the northern United States were formerly largely conifers; but so valuable were they as lumber that the more accessible ones have been cut down, and the larger part of the present lumber supply comes from the Pacific states and from the South. Vascular or woody tissues reach a high state of development in the stems and roots of conifers. To the foliage leaves of mature pines the name "needles" is applied. These needles are highly specialized in structure and are adapted to resist extremes of conditions. Morphologically they are grouped in fascicles of two, three or five needles, depending upon the species.

It has been indicated that the seed contains an embryo plant. In the pine, this embryo plant is surrounded by a considerable food storage layer called the *endosperm*, and the whole is enclosed by the seed coat, or *integument*. Maturity of the seed is accompanied by a certain amount of drying out and by a period of inactivity or dormancy. A renewal of growth is shown by the embryo when, under favorable conditions, the seed absorbs water, and thus germination or sprouting ensues. The young seedling, free of the seed coat, will be found to consist of root portion, bud or *plumule*, and a whorl of long, green seed leaves or *cotyledons*.

Angiosperms. The angiosperms, or true flowering plants, include the great majority of the familiar flowers and weeds of field and garden, as well as all the trees and shrubs except the gymnosperms, referred to above. Besides the possession of seeds and of a complex tissue system (see special discussion later) in which vascular or woody elements attain a further advanced state of differentiation, the angiosperms also exhibit the highest evolutionary development through the production of flowers. A *flower* may be regarded as a shortened branch with highly modified sporophylls, and commonly with other floral leaves often conspicuously colored. Our esthetic interest is awakened by the beauty of many flowers, but the importance of the flower to the life of the species of plant lies primarily in the possession of sporophylls, for these are concerned with the reproduction and perpetuation of the species. Color and fragrance are likewise useful, and both are factors in attracting insect visitors, so necessary for the pollination of certain species.

Parts of the Flower. It is important to know all parts of the flower, and as a representative type the apple or the wild rose may

serve. In such flowers as these there are at least four sets of structures that attract particular interest. The outer set of parts (green in these plants) constitute the *calyx*, the individual leaves of which are the *sepals*. Next there is a set of showy leaves known as the *corolla*, the individual parts of which are *petals*. Within the petals are a group of relatively small sporophylls (microsporophylls) and these are the *stamens*. The central and last structure constitutes a united set, termed a *pistil*, made up, however, of several parts or *carpels*. More immediately concerned with reproduction are the stamens and pistils. In the case of the flower under consideration, each group of carpels has an enlarged basal *ovule sac*, a terminal *stigma* and a connecting shank known as a *style*.

The terminal enlarged part of the stamen is an *anther*, and in this the dust-like *pollen* is produced. In the ovule sac there are differentiated the ovules within which the egg gametes are produced. Pollen grains distributed by insects, wind or other agencies lodge on the stigma, germinate (this is then the male gametophyte), and the germ tubes grow down the style and into the ovules, where gametic union occurs. Following this, embryonic development and seed formation proceed until the seed ripens, or matures.

The Significance of Scientific Plant Names. In speaking of the lower classes of plants, including the algae, mosses and ferns, there have been used as scientific names only the class names (for example, *Bryophyta*) and certain common or popular names. But in discussing the higher plants it is extremely useful to become better acquainted with scientific names and to learn how these are employed. It is not difficult to do so when we make the effort, and it is never necessary to make the use of scientific names a burden. It is more particularly necessary if an effort is made to get more intimate knowledge of plant relationships, or if one attempts to use the manuals or floras prepared for the identification of either wild or cultivated plants. All those interested in knowing plants will want to use these manuals sooner or later, for they can add greatly to our out-of-doors enjoyment.

There are various subdivisions of the classes of organisms that have been referred to, but for the sake of simplicity we need consider only three categories—families, genera and species. As an example of a plant family we may consider the rose family. There are perhaps 2,500 different kinds (species) of plants in this family. It includes, among many others, such groups as roses and brambles, plums and cherries, the pear and the apple, spirea and mountain ash. All such plants are included in the family *Rosaceae*. Why are these grouped into one family? The answer is that all possess a wild "rose" type of flower. It is, then, the type of flower, and not always the showy parts of the flower either, that determines relationship. The strawberry and the apple are plants of different extremes in size, but this is of little significance.

All kinds of brambles, including many sorts of blackberries, dewberries and raspberries, are placed together in a smaller group, a *genus;* in this case it is the genus *Rubus*. Members of this genus are more closely related one to another than are members of different genera. They may be related through more detailed floral characters or through other characters. Each kind of bramble, such as the high bush blackberry or the trailing blackberry, constitutes a distinct *species*, and the former is *Rubus frondosus*, the latter *Rubus trivialis*. Each of these is the true scientific name of a kind of plant. This name does not vary with locality or with language, as common names often do. The name is a binomial (two names), and generally the specific name suggests some characteristic of the particular kind of plant; thus *Rubus rosaefolius* is the rose-leaved blackberry.

In the next few paragraphs it will be helpful to mention, under the greater divisions of the flowering plants, a number of the important families. And at the close of this article, in a list of common food plants, the generic and specific names (the scientific name of each) will be included for reference. (See also the extensive "Dictionary of Plants.")

Major Divisions of Angiosperms. The angiosperms are subdivided into two groups. In one of these the venation of the leaves is parallel, as in the corn, and on germination of the seed the young plantlet exhibits a single seed leaf (cotyledon); such plants are *monocotyledons*. The second group is characterized by netted, or reticulate, venation of the leaves, as in the bean plant or in the rose. In all these there are two seed leaves in the young seedling, and it will be recalled that in the bean these are thickened, representing reserves of organic food. Plants with two seed leaves are called *dicotyledons*. There are other characters—both of floral parts and of inner structure—that are generally distinctive of the two groups, as further study will reveal.

Among the several hundred families of flowering plants known, 167 have been listed as furnishing our cultivated crops, together with other useful and ornamental trees, shrubs and annuals actually planted and cared for by man.

The Monocotyledons. From the monocotyledons there come such families as those of the grasses (*Gramineae*), furnishing cereal grains, pasture and ornamental grasses; tropical palms (*Palmaceae*), including the date and coconut palms, besides many that are cultivated in greenhouses; lilies and related plants (*Liliaceae*), affording many attractive flowers; bananas and plantains (*Musaceae*); and the highly prized orchids (*Orchidaceae*), famous alike for the delicacy and variety of the wax-like flowers and for the remarkable modifications in floral parts, the latter having come about in adjustment to insect pollination. Beginning with the grasses and closing with orchids, we see extreme differences in floral anatomy. The grass "flower" may be largely a scaly leaf or bract (chaff, husk) with long or feathery styles. The silk of an ear of corn is made up of hundreds of long, flexible styles which grow out beyond the husks and catch the pollen distributed by the wind. On the other hand, the beauty of form and color in the petals of floral leaves of lilies, irises and orchids enlist the admiration of all.

The Dicotyledons. The dicotyledons are nearly five times as numerous as are the monocotyledons, and at the same time the former group is regarded as geologically the older; it has attained far greater diversity in form, and has advanced to higher types of development. Among families exhibiting the less complex types of floral structure there are the willows and the poplars (*Salicaceae*), with simple flowers in spike-like branches called "catkins." Related to the willows are other families without showy floral parts such as the walnut-hickory nut family (*Juglandaceae*), the birch-alder (*Betulaceae*), the beech-oak family (*Fagaceae*), and the elms (*Ulmaceae*). These families of trees and shrubs are often classified as "primitive" because of the simple floral parts, but there is much to suggest that this simplicity is merely one line of development, made prominent by the emphasis on floral features.

In a varied group of families, including the pinks, sweet Williams, carnation (*Caryophyllaceae*), water lilies (*Nympheaceae*), buttercups, columbines, peonies and clematis (*Ranunculaceae*), there are included many attractive wild and garden plants of much interest. In all these the petals are distinct (polypetalous) and the carpels either separate or united. The various kinds of magnolia, as well as the sweet bay and the tulip tree (*Magnoliaceae*), constitute an impressive though small family considered by some to qualify as a present-day representative of a primitive flower. The petals of magnolia are often very showy and they vary in number, while the carpels are usually aggregated into a cone-like structure.

In the manuals, the rose family (*Rosaceae*) and the pulse family (*Leguminosae*) are neighbors, and together they constitute a very considerable part of the separate-petal series of families. As a whole the rose family is rather heterogeneous (as indicated in a previous paragraph); but we cannot fail to note among the wild and cultivated blackberries, roses, cherries and the like several common features. Thus (a) the corolla and stamens are inserted on the calyx tube, the latter being often united with the wall of the ovule case, so that the calyx tube forms a part of the developing fruit; and (b) the stamens are rather numerous and in cycles. In the pulse family there are several thousand species, among which are the lupines, clovers, beans, peas and acacias. Generally the corolla is papilionaceous, or butterfly-like, with petals more or less like those of the sweet pea, and the fruit is characteristically a pod or legume.

Among the families of dicotyledons in which the petals are united (*gamopetalous*), a few only may be mentioned here. The mints (*Labiatae*), typified by the garden salvia, are fragrant herbs and shrubs with flowers commonly two-lipped. The nightshade family (*Solanaceae*) includes the potato, tomato, egg plant, tobacco and petunia, with prevailingly rotate flowers and fruit—a "berry" (as in tomato) or capsule (as in Jimson weed). Our table melons of various sorts are the fruit of certain members of the gourd family (*Cucurbitaceae*).

Botanists generally agree in placing at the pinnacle of development in the plant kingdom the composite family (*Compositae*). This is the family of sunflowers and goldenrods, asters and thistles, chrysanthemums

and dahlias. It has also given us lettuce, bur artichoke and salsify. It is a huge family with perhaps 12,000 species; with few exceptions they are annuals or perennial herbs, and the woody ones are not trees. The outstanding characteristic is the compact head of many flowers—some with ray flowers (as in sunflowers) and some without (as in thistles). The fruits are hard and one-seeded (*akenes*), and these are often provided with a feathery appendage, or pappus (as in dandelion), the pappus serving as an efficient adjustment to wind distribution of the seeds.

HISTOLOGY

Histology, sometimes regarded as a division of microscopical anatomy, deals with *tissues;* that is, cells more or less similar in form, constituting a specialized area of the cell body. Accordingly, tissues may be of as many kinds as there are kinds of cells. A convenient classification of tissues is as follows:

Meristematic, or young, tissue (*meristem*) consists of thin-walled cells rich in protoplasm, or living substance. They are able to divide and thus continue the growth of the organ. All other tissues are derived from meristem by differentiation or modification. *Cambium*, the layer of active growth and cell formation in stems and roots of dicotyledons, is a form of meristem.

Parenchyma, or soft tissue, consists of mature, thin-walled, usually short cells which have attained their growth, as the tissue of ripened fruits and the green tissue of leaves. The cells contain less protoplasm than the meristem.

Collenchyma, or thick-angled tissue, consists of long prismatic cells with thin walls, but with the longitudinal angles much thickened. In many stems it occurs as a strengthening tissue just beneath the epidermis.

Sclerenchyma, or stone tissue, consists of thick-walled, usually short cells, so tightly packed together that they form a hard mass, as in the shells of nuts, for example, in hickory nuts, walnuts, filberts, and in the "stones" of many fruits, as in plums and cherries.

Fibrous and *bast* tissue consists of thick-walled, elongated cells so tightly packed together that they make up the fibrous part of the wood (wood fibers) and of bark (bark or bast fibers) of the stems of most higher plants. Bast fibers are the basis of rope making and of linen manufacture.

Sieve tissue consists of elongated, usually large cells, more or less united into tubes, and having only slightly thickened walls. The name is given on account of the fact that the transverse partitions between the cells are perforated in a sieve-like pattern, and through these perforations the protoplasm connects from cell to cell. Sieve tissue occurs primarily in the young bark. It is important in conveying organic food material.

Tracheary tissue, like the preceding, is a tubular tissue, but here the continuity of the cavity is usually more complete. The walls are somewhat thickened—in rings, spirals or in more complicated ridge systems. When young, these tubes contain protoplasm; but eventually they contain water or air. Tracheary tissue occurs in the woody parts of stems and leaves. It is a greatly differentiated tissue, losing protoplasm and dying with complete development. Its true function, that of water conduction, then begins.

Milk cells and tubes (*laticiferous tissue*) occur singly or in masses in many plants, and are easily recognized by their milky contents, as in the many kinds of milkweeds. The milk (*latex*) is often very poisonous; rarely is it wholesome. In some cases it contains caoutchouc, from which India rubber is manufactured.

Epidermal tissue is usually a single layer of cubical cells, constituting the outer layer of leaves, young stems and roots.

PROCESSES GENERALLY CHARACTERISTIC OF LIVING ORGANISMS

Ordinarily it is easy to ascertain in a general way that an organism is living, because it exhibits some of those activities that are associated with life. At the same time, it is well to enumerate and analyze these characteristics. Conspicuous indications or criteria of life are: (1) the absorption of water and food materials in solution; (2) the use of food materials in building up new substance; that is, in building protoplasm or storing food products—both phases of metabolism; (3) the breaking down, or physiological combustion, of food products, with the liberation of energy required in various activities, a process called respiration; (4) growth, which may be partially defined as usually an increase in size or a differentiation in structure; (5) reproduction, involving the formation of new organisms, whether by division of the existing organism, or by the development of special cells or structures ultimately participating in the formation of a new individual; and (6) irritability, the power to respond to the influences and changes in the various factors that constitute the environment of the organism. The green plant is characterized by another process; to it has fallen the responsibility of making all organic food material required by living things (see later discussion of photosynthesis).

The characteristics enumerated are some of the important physiological processes, and some further consideration of several of these should be illuminating in respect to plant activities.

Growth. Growth is a familiar and obvious characteristic of the living organism. Favorably situated, the bean seed germinates and grows into a bean plant; a potato tuber sprouts, and as the new shoots grow the old tuber is gradually exhausted of food, as a result of which it decays or shrinks as the tissues disintegrate. Rapid growth usually presupposes a reserve of stored food material.

Several types of growth may be noted as the leaf bud of the elm, for example, unfolds in the spring. The bud swells, and with the increasing size the bud scales drop away, revealing an elongating shoot axis having miniature leaves. As shoot elongation continues, the leaves expand and differentiate, and soon a full-fledged elm shoot is the perfected product. In making such an observation we have witnessed development and differentiation. These are valuable ideas, and they are always associated with extensive growth in a complex plant.

Growth of a tissue or organ may consist of an increase in the number of cells, or in the size of cells, or both, and generally there is considerable differentiation or change in the nature of the cells. Growth rate of any plant is a function of the specific inheritance of the plant and of the favorableness of the environment. The bamboo grows with great rapidity, the oak with extreme slowness; the maximum relative growth rate of each is highest with adequate sunlight and warmth, moisture and soil nutrients. Every structure, organ or individual has not only growth characteristics peculiar to itself, but also different requirements as to growth conditions. Hence, we have plants which grow primarily in the spring, or primarily in midsummer, as well as those which grow in all seasons.

As the root of the sprouting bean emerges, cell formation is active in the region of the tip. Back of the tip, cells rapidly elongate, continually increasing the length of the root. As soon as the cells in any zone cease elongating root hair development occurs, and since these hairs greatly increase the root surface, they are efficient agents of water absorption.

Absorption and Water Relations. Active living plants contain a high percentage of water, and every growing plant must, in some way, be in contact with a water supply. The familiar plant of the garden has its roots fixed in the moist soil, while the water weeds and the immersed or floating algae are obviously more or less surrounded by free water. In a complex plant the cell walls are in close contact, and even though cells of the leaves may be many feet from the absorbing roots, the distribution of water is so perfect that we must think of indirect water contact with the soil through long chains of tissue cells, each cell in turn taking its water from some other cell or conducting vessel nearer the constant supply. Unless a plant contains a quantity of dead tissue, as in trees or shrubs, the water content is usually four-fifths or more of the fresh weight.

No living thing can grow and develop without an adequate supply of water. The water plant is in direct contact with water through much or all of its surface. The roots of the soil plant are well distributed and thus a large surface of contact with soil moisture is established. A few plants, like the Florida "moss" (which hangs from the limbs of trees), obtain their moisture by condensing the water vapor (humidity factor) of the air.

Water is constantly being absorbed by the active root, that is, the plant is exerting a pull on the soil for water. This pull could be adequately described only after such a consideration of the nature of diffusion and of the movements of water and of substances in solution through membranes (a process called *osmosis*) as would not be practicable in this connection.

The plant is provided with certain pores (*stomata*), primarily in the leaves, through which gases diffuse into and out of the tissues. Through these pores, which are quite consistently open during daylight, water vapor is given off. This water loss is called *transpiration*. Water loss is greatest when the air is driest. Under conditions of high temperature, low humidity and some wind action, any plant has, so to speak, a fight for life, since excessive wilting may mean death. To withstand desert conditions plants must be able either to conserve water or they must be

adjusted to withstand a severe water loss. Some of the water relations of plants constitute an important part of ecology.

Photosynthesis. We ourselves, and all other animals large and small, as well as fungi and bacteria, owe our existence directly or indirectly to green plants, since these alone can manufacture appreciable amounts of the necessary organic foods from the crude materials, that is from carbon dioxide of the air and from water, largely absorbed from the soil. Next to the elements of water, carbon constitutes the largest part of all living things. The source of this carbon is the extremely small percentage of carbon dioxide of the air, which is (with water) transformed into sugar (or starch) by the green leaf. Besides the food materials referred to, and the living cells, the factors important in this process are (a) the pigment chlorophyll and (b) sunlight, the source of energy for the changes involved. The process is a photosynthesis, hence the name. It is a process not yet finally understood as to chemical nature, and accordingly it cannot be imitated in the laboratory. We can say this much, at least, that the first and last steps are understood, and the chief product (sugar) and by-product (oxygen) are readily identified. Besides many valuable facts concerning the process in general and concerning the absorption of light of different wave lengths, facts also as to the chemistry of chlorophyll and theories as to the course of chemical action have been developed, and these promise future possibilities of great interest. Practically, the relation of the plant to intensity and duration of light have proved to be profitable fields of study and full of applications. For one thing, in very recent years it has been made clear that growth and fruiting of plants may be differently related to lengths of day. There are species that may be brought into flower very quickly by reducing the length of day, and there are others thus encouraged by increasing the length of day. As ordinarily grown, with the full effect of the long days of summer, the cosmos grows tall and does not flower until the shorter days of late summer or early fall. If, however, the plant is shaded for a few hours each day when it has reached no more than a foot in height, it will promptly be thrown into flower. With respect to flowering, therefore, the cosmos is a short-day plant. Considering the relations of plants in general to sunlight, it is perhaps not strange that these are characterized by such an harmonious development of the whole organism, and by so marked an adjustment of the leaves that all receive a maximum of the light that may fall upon them.

COMMON FOOD PLANTS

	Probable Early Home	Time of First Cultivation
Almond (*Prunus communis*, Fritsch),	Mediterranean countries; Western Asia	Prehistoric
Apple (*Pyrus malus*, L.),	Europe, Southwestern Asia	Prehistoric
Apricot (*Prunus armeniaca*, L.),	China	Prehistoric
Artichoke (*Cynara scolymus*, L.),	Mediterranean	Ancient
Artichoke, Jerusalem (*Helianthus tuberosus*, L.),	North America	Modern
Asparagus (*Asparagus officinalis*, L. var. *altilis*, L.),	Europe, Western Asia	Ancient
Avocado (*Persea americana*, Mill.),	Tropical America	Modern varieties
Banana (*Musa paradisiaca*, L. var. *sapientum*, Kuntze),	Southern Asia	Prehistoric
Barley (*Hordeum vulgare*, L.),	Western Asia	Prehistoric
Bean, Kidney (*Phaseolus vulgaris*, L.),	South America	Prehistoric
Bean, Lima (*Phaseolus limensis*, Macf.),	Brazil	Ancient
Beet (*Beta vulgaris*, L.),	Asia, Mediterranean countries	Ancient
Brazil Nut (*Bertholletia excelsa*, H. & B.),	Amazon Valley	Still wild
Buckwheat (*Fagopyrum esculentum*, Gaertn.),	Northern Asia	Modern
Butternut (*Juglans cinerea*, L.),	Eastern United States	Modern
Cabbage, Kale, etc. (*Brassica oleracea*, L. [vars.]),	Europe	Prehistoric
Cacao (Source of "Chocolate") (*Theobroma cacao*, L.),	Tropical America	Prehistoric
Carrot (*Daucus carota*, L. var. *sativa* D. C.),	Europe	Ancient

DICTIONARY OF PLANTS

Abaca (*Musa textilis*). This important fiber plant is native to the Philippine Islands. It belongs to the banana family but its fruit is not good to eat. The fiber, called Manila hemp, is used in the best grades of ropes and cables, where it wears well and does not easily kink or jam in pulleys. The abaca plant requires a damp, warm climate and a deep rich soil. Many attempts to introduce its culture into America have always been failures.

Acacia (*Acacia* spp.). Trees properly of the genus *Acacia* and a name sometimes given to trees of the pea family. The majority of acacias are found in warm, dry places. They usually have thorns or spines. An African species yields gum arabic. Hard lumber is obtained from the trees. In North America the acacias seldom attain any considerable size.

Agave (*Agave* spp.). A desert plant of which the best known representative is the century plant (which see).

Ageratum (*Ageratum Houstonianum*). An easily grown garden flower used for edges and borders. Though commonly blue, the blossom is sometimes white or rose-colored. Because of the general effect of a fuzz over the flower heads, the plant is also called "floss flower."

Ailanthus (*Ailanthus glandulosa*). A large-leaved tree, native to China and naturalized in America and now often found wild in our forests. The staminate flowers have a disagreeable odor. The fruits resemble twisted sheets of paper about two inches long and bear a seed in the center. A common name for the ailanthus is "tree of heaven."

Alder (*Alnus* spp.). The alders are close relatives of the birches and the hornbeams. They are small water-loving trees of rapid growth. The many species include the black, the seaside and the Oregon alders. The wood is soft and not valuable for lumber but is used in making charcoal. The bark is sometimes used in tanning.

Alfalfa (*Medicago sativa*). A valuable legume of the pea family, probably native to southwestern Asia or southeastern Europe. The name is from the Arabic which means "best fodder" and indicates the use of the plant. In some parts of our country alfalfa is called "lucerne." It has a small purple flower and seeds are produced in a twisted pod resembling a snail shell. Properly cured alfalfa hay is relished more than any forage plant by farm animals. It is an excellent pasture crop and has high feeding value when the dry hay is ground to make alfalfa meal.

Algae. A plant subkingdom including most of the pond scums and all the seaweeds and ranking lowest in the scale of plant life. The four general classes of the algae are the blue-green, green, brown and red. Most of the green forms are found in fresh water and include *Protococcus*, *Spirogyra* and *Cladophora*. The vast masses of the Sargasso Sea are brown algae. The kelps of our ocean waters are the most important species of brown-algae. Most red algae are found in very deep salt water. Irish moss is a red alga. Desmids and diatoms are interesting forms of algae.

Alligator Pear. See Avocado.

Allspice (*Pimenta officinalis*). The berry of the pimento, an evergreen tree of the myrtle family of the West Indies. The name is derived from the fact that the pungent, aromatic flavor of the berry seems to unite those of the cinnamon, clove and nutmeg. The fruits are picked unripe and cured by artificial heat. Jamaica is the principal source of supply and the spice is sometimes called "Jamaica pepper."

Almond (*Prunus communis*). A small tree of the genus *Prunus* of the rose family, grown for its nut. The almond requires a warm climate such as southern Asia, the Mediterranean region and southern California, where it is grown commercially for its fruit.

There are bitter and sweet almonds. The bitter varieties are used for flavoring extract and for their prussic acid. The sweet almonds are used in candy and desserts; they are of three classifications—hard-shelled, soft-shelled and paper-shelled. A related ornamental shrub is the flowering almond.

Aloe (*Aloe* spp.). Plants of the lily family and natives of warm countries. The juices of these plants are used for medicinal purposes. Aloes vary in height from small plants to trees of thirty feet.

Alyssum (*Alyssum* spp.). A genus of herbs originating in the Old World. Best known is the sweet alyssum, a common garden flower used for edges and borders. It produces fragrant, white clusters of bloom. The golden alyssum is a prolific small golden-yellow flower of early spring.

Amaranth (*Amarantus* spp.). The amaranth is often a troublesome weed. One species is a tumble-weed and behaves in a manner similar to the Russian thistle. The common amaranth occurs in gardens and is known as "redroot" or "pigweed." Some of the amaranths, as the species called "love-lies-bleeding," are grown as garden flowers.

Amaryllis. Bulbous plants, more properly called hippeastrums. The only true amaryllis commonly grown is the belladonna lily of California. The hippeastrums are usually grown in pots. The flowers are typically produced before the leaves and often are large and of great beauty.

Anemone (*Anemone* spp.). There are many kinds of anemones in our forests. Best known is the wood anemone with its delicate little starlike flowers of early spring. Many varieties, notably the Japanese anemone, are grown as garden flowers. The pasque flower, chosen by South Dakota as the state flower, is an anemone.

Anise (*Pimpinella anisum*). An aromatic herb grown in gardens for its seed and leaves and for the oil from the seeds. Anise is a member of the parsley family and a native of the Mediterranean shores. The seeds are used for seasoning and flavoring condiments, cheese and candy. The oil is used in medicine as a flavor. The oil and seeds are also used in soaps and perfumes. The leaves are used for garnishing and seasoning.

Apple (*Pyrus malus*). The apple tree has been cultivated for many centuries. It goes back to the wild apple of southwestern Asia. Today the common apple and the crab apple are important. There are varieties of every description from sweet to sour and ripening from early June to late fall. Japan has produced apple trees with fruit the size of cherries, cultivated entirely for their flowers. Apples are popular as an edible fruit, fresh, canned and evaporated.

Apricot (*Prunus* spp.). A garden fruit of the rose family, native to the Orient and now grown in mild temperate climates throughout the world. The fruit appears to be intermediate between the peach and the plum. Apricots require careful handling as they are easily bruised. They are used fresh, canned and evaporated.

Arbor Vitae (*Thuja* spp.). The name means "tree of life," although we commonly see this group of evergreen trees growing in cemeteries. The arbor vitae is distinguished by its small leaves pressed flat and close to the stem. The leaves are supplied with an oil which gives a pleasant fragrance to the plant.

Arbutus or **Trailing Arbutus** (*Epigaea repens*). A very early spring wild flower with fragrant, waxy-white to pink blossoms found in light sandy loam in forest areas. It has been extremely difficult to coax this dainty woodland flower to live in civilization, but recently government botanists have successfully propagated it.

Artichoke (*Cynara scolymus*). The true artichoke is a thistle-like plant with long prickly leaves and heads of white or violet-colored flowers. The base of the unopened flower bud and the thick scales around it are eaten as a food. The Jerusalem artichoke (*Helianthus tuberosus*) is a species of sunflower bearing tubers which are used for food.

Ash (*Fraxinus* spp.). The ash tree is tall and stately with smooth bark checked into small plates. It belongs to the olive family. The wood is very useful for tool handles, oars, baseball bats and other articles requiring lightness and strength. Among the species of the ash are the white, black, red, green, blue and Oregon ash.

Asparagus (*Asparagus officinalis*). This hardy member of the lily family produces tender young shoots in the spring. These shoots are eaten as a green vegetable. They were used by the Greeks and Romans in ancient times. Besides the common garden form there are other species, grown for ornamental uses.

Aster (*Aster* spp.). There are more than 200 species of asters known, most of which are found in America. In England the wild aster has been improved and is called "Michaelmas daisy." These hardy perennials bear attractive flowers ranging from white to dark purple and including pink, rose and violet shadings. Although in meadows asters may become troublesome weeds, they deserve a place in the flower garden. The China aster, a highly developed garden flower, is a member of another genus (*Callistephus*) of the same family.

Avocado (*Persea americana*). Also called "alligator pear," a tropical laurel whose fruit attains the size of a large pear. The fruit has a green or purple skin and a soft, oily pulp surrounding a large seed in the center. The fruit is cut open and eaten like a melon or used in salad. The tree grows to a height of fifty feet and with its thick green leaves is attractive for shade. (See also Laurel.)

Azalea. A genus of deciduous-leaved plants of the heath family separated by practical growers from evergreens which are put in the genus *Rhododendron*. The azaleas are natives to America, found in swamps and forests, but they do not respond readily to cultivation. The pink azalea is a beautiful shrub whose flowers resemble those of the honeysuckle. This handsome flower needs protection to prevent its extinction at the hands of thoughtless collectors.

Bacteria. Microscopic plants which live as parasites or saprophytes. Some are harmful and others are beneficial to man. Some bacteria produce fermentation, as of milk or cider. Others stimulate decay. Among the useful bacteria are those which inhabit the roots of legumes and utilize the nitrogen of the air. Pathogenic bacteria cause diseases in plants and animals. Tuberculosis, typhoid fever and lockjaw are examples of diseases of man caused by bacteria. The black rot of cabbage and the wilt of the tomato and potato are examples of plant diseases caused by bacteria.

Balm of Gilead. See Poplar.

Balsam (*Impatiens balsamina*). The garden balsam is called *Impatiens* because the seed pod irritably bursts open when touched. The double-flowered sorts are seen now most commonly. The color of the flowers shades from white to deep crimson.

Balsam Fir. See Fir.

Bamboo (*Bambusa* spp.). Plants of the grass family, sometimes attaining heights of more than 100 feet. About 200 kinds of bamboo are known. Some bloom regularly and others have never been known to bloom. Bamboos are mainly tropical plants. Only two kinds are found which are native to the United States and they grow along streams and swamps in the South and form "cane-brakes." Bamboo is very useful. It is made into furniture, floats, buckets and even houses. Paper is made from bamboo. The seeds are used to eat as are also the tender young shoots.

Banana (*Musa paradisiaca* var.) Largest of treelike, herbaceous plants. The stem attains a height of from ten to thirty feet and the leaves are from five to twenty feet in length. It is a native of tropical countries and has been raised to some extent in the southern United States. The banana is used for its fruit and also for its fiber and for ornament. The plant produces but one bunch of bananas and dies down. The stem is then replaced by suckers which spring up from around the base. The red banana is thicker and sweeter than the more commonly grown yellow variety.

Banyan Tree. See Fig.

Barberry (*Berberis* spp.). A group of shrubs with handsome foliage and fruits which persist through the winter. The three best known species are the Japanese, the purple-leaved and the common barberry. All are valuable for landscape effects. However, the common barberry should not be used in wheat-growing districts as it harbors a destructive fungus, the black stem rust of wheat. The Japanese barberry may be distinguished from the common species by the leaf edges which are smooth and by the spines which occur singly in the Japanese.

Barley (*Hordeum vulgare*). A cereal grain of which wild types are still common in Asia. Of the grains, barley most nearly resembles wheat. In the United States most of the barley is grown north and west of the regions devoted to corn. Barley is chiefly used as feed for animals. The grain has no gluten and cannot be made into a raised loaf of bread. It is used as a breakfast cereal.

Basswood or **Linden** (*Tilia* spp.). A popular rapid-growing shade tree with fragrant cream-white flowers, whose nectar bees make into excellent honey. The wood is used for furniture, woodenware, cooperage, paper pulp and charcoal.

Bean. A name applied to a large number of the legumes. The common bean consists of field and garden types and these are divided into tall climbing or pole varieties and smaller, dwarf or bush varieties. Beans are used for food green, as snap or shell, and dried shelled. Beans require a fairly warm soil and should not be planted until danger of frost is gone. In addition to the ordinary garden snap bean, the Lima is another favorite. The Limas are less hardy than the common bean.

Beech, American (*Fagus grandifolia*). A tree widely distributed throughout the eastern United States and the only species found in our country. This symmetrical tree with its silvery-gray bark marked with blotches of paler hue is beautiful and useful. Beech lumber is excellent for furniture, flooring and handles of tools. Since it is hard and resistant to water, beech is well adapted to the making of bowls and for construction work under water. Beechnuts have a rich delicate flavor that well makes up for their small size. Due to its ability to propagate rapidly from sapling growths around the trunk, beeches often take possession of areas, resulting in pure forests of the tree.

Beet (*Beta vulgaris*). The beet is a descendant of a perennial herb of southern Europe. Our beet is a biennial, producing a bulbous root one year and seed the second, although as a garden crop we purchase seed and raise the beet as an annual. Beets are grown for their edible foliage, as in Swiss chard. They are also grown for their roots, as in garden beets, sugar beets and mangel-wurzel. The beet "seed" is really a group of seeds, and when the plants come through the ground they soon need thinning.

Begonia. A large family of flowering plants divided into several groups including (1) the fibrous-rooted, (2) tuberous-rooted and (3) those with rhizomes which are cut into pieces and planted like seeds to raise new plants. The color of the flowers run from red through pink to white. Begonias are grown as house plants and outdoors in formal gardens.

Belladonna or **Deadly Nightshade** (*Atropa belladonna*). A plant grown for its leaves and roots which contain an alkaloid used in medicine. The purple berries are poisonous. Belladonna belongs to the *Solanaceae* family and is therefore a close relative of the common potato and the tomato.

Bindweed or **Morning-Glory** (*Convolvulus sepium* and *arvensis*). The bindweed is found all over the United States. It is a trailing vine growing along walls and hedges and in fields. The vines have deep-running rootstocks, spear-shaped leaves and pink to white bell-shaped flowers. As a weed it is one of the farmer's worst enemies and a close watch must be made of seed sown, especially wheat. The black bindweed, or wild buckwheat, belongs to the buckwheat family and is a lesser pest than the morning-glory. The morning-glory is a perennial, while the wild buckwheat is an annual and reproduces each year only from seed.

Birch (*Betula* spp.). Birches are widely distributed in North America, Europe and Asia. The early American Indian found the birch bark admirably adapted to the making of a light canoe and we know his favorite species today as the canoe or paper birch. The white birch of Europe is grown widely as an ornamental lawn and park tree in our country. Other species include the yellow, red and sweet or black birch.

Bittersweet, Climbing (*Celastrus scandens*). The only North American species of the staff-tree family. This is a good trellis-plant, especially desired for its berries which turn from green to yellow and then burst to expose their scarlet-coated seeds with their contrasting orange-yellow envelopes. These last all winter and make attractive clusters indoors throughout the winter.

Blackberry (*Rubus* spp.). A perennial plant grown for its edible berries. It is (with the raspberry and the dewberry) one of the group of thorny plants known as "brambles." The blackberry propagates rapidly from suckers which grow from the root, and cultivation and pruning are necessary in commercial growing of the plant. The plant is a native of our country and the largest cultivated varieties have been developed therefrom. Foreign varieties have been introduced to a certain extent also.

Bleeding Heart (*Dicentra spectabilis*). A garden flower with rosy red and pink heart-shaped flowers borne on tall, graceful light-green stems. The flowers are produced in sprays. The new shoots start each year from the roots in early spring and the flowers appear in May.

Bloodroot (*Sanguinaria canadensis*). An early-blooming woodland flower. The flower bud arises from out a papery sheath and unfolds into a white, fragile bloom. The plant has a thick rootstock which makes it easy to transplant to a rich shady corner of the garden. All parts of the plant and especially the rootstock give out a staining orange-red juice which won for the bloodroot the name of "Indian paint." Old-fashioned mothers used to drop the juice on lumps of sugar and use them for coughs and colds.

Bluebell or **Harebell** (*Campanula rotundifolia*). This bell-shaped blue flower grows drooping from hair-like stems. It prefers moist rocky uplands and is often found in lofty crevices in rocks. Its range includes the northern half of our country from New Jersey to California. In poetry the plant has been immortalized as the "bluebell of Scotland."

Blueberry. See Huckleberry.

Blue Grass (*Poa* spp.). A name applied to various species. The one commonly referred to is known as Kentucky blue grass or June grass. This was first described in the writings of the Swedish botanist, Kalin, in 1758. Blue grass grows best in humid regions and its range is quite general over the United States.

Bouncing-Bet or **Soapwort** (*Saponaria officinalis*). An attractive flower with showy white clusters of bloom found along roadsides. It becomes an undesirable weed in pasture lands. The name "soapwort" refers to the fact that the broken leaves agitated in water make a lather which was used by our Colonial ancestors for washing clothes.

Box Elder. See Maple.

Box Tree (*Buxus sempervirens*). An evergreen shrub of the box family used for hedges and borders. It is grown mainly along the eastern coast of our country. It requires considerable care to maintain the shrub in good health. The hardwood is sought for wood engraving and for use in wind instruments.

Brazil Nut (*Bertholletia excelsa*). The Brazil nut grows in Brazil on a tall tree, often exceeding 100 feet in height. The nuts are contained in a large spherical pod. The nuts have a creamy-white meat and are used for eating. Their oil is valuable for burning.

Breadfruit (*Artocarpus incisa*). A tropical tree native to the East Indies. It has long thick leaves and yields an edible fruit, globular in shape and from four to six inches in diameter. To a limited extent the breadfruit has been grown in Florida. In tropical countries the fruit is cooked and eaten as a vegetable.

Bridal Wreath. See Spirea.

Broomcorn (*Andropogon sorghum*). A sorghum,

grown since Colonial days in America for its loose, open head which is made into brooms. Two kinds are grown: the standard, which grows from ten to fourteen feet in height, and the dwarf, from four to six feet tall.

Brussels Sprouts. A variety of the cabbage species, requiring a long, cool growing season. On the stems, in the axils of the leaves, are produced buds or "sprouts" resembling miniature heads of cabbage. These are cooked and eaten as vegetables.

Buckeye (*Aesculus* spp.). A group of native American trees which together with the horse chestnut (*A. hippocastanum*) make up the genus *Aesculus*. The horse chestnut, however, comes from Europe and Asia. The brown nuts are marked with a light brown patch which suggests the partly-opened eye of a deer and is responsible for the name "buckeye." The great abundance of the Ohio buckeye has given Ohio the name "Buckeye State." Among other buckeyes are the sweet and the California species.

Buckthorn (*Rhamnus catharticus*). This relative of *Cascara sagrada* is a shrub of the buckthorn family used as a hedge. It bears small yellowish-green flowers and produces blue-black berries which are used as a pigment by painters.

Buckwheat (*Fagopyrum esculentum*). A native grain of Asia and cultivated for a thousand years by the Chinese. Buckwheat was introduced into our country from Europe. The plant has similar uses too, but is not one of the cereals. It is a close relative of the smartweed and dock as may be seen by examining the triangular fruit of this group of plants. Most of our buckwheat crop is grown in the northeastern part of our country. Buckwheat flour is used for griddle cakes. Buckwheat middlings are used for cattle food and the entire grain is fed to poultry.

Burdock (*Arctium* spp.). A biennial weed with pink flower clusters, belonging to the family *Compositae*. The sticky burrs are effective in spreading the seed. The roots are prized as food by the Japanese in California and both the roots and seeds have some medicinal value.

Buttercup or **Crowfoot** (*Ranunculus* spp.). A large group of wild flowers, usually with acrid, caustic juices. The yellow cup formed by the petals is held by children under the chin to test one's liking for butter. Included among the buttercups are the tall meadow, creeping bulbous and the swamp or marsh buttercup.

Butterfly Flower (*Schizanthus pinnatus*). Sometimes called "poor man's orchid," this delicately cut flower of many hues resembles butterflies. Although butterfly flowers are quite hardy and flourish outdoors, they respond well to greenhouse culture where they sometimes grow to a height of four or five feet.

Butterfly Weed (*Asclepias tuberosa*). With fragrant clusters of orange bloom this flower is the handsomest of all the milkweeds. When in full bloom the plant is usually surrounded by butterflies and other flying insects. Fortunately this wild flower can easily be transplanted to the home garden where it does well in full sunlight and in dry places. See Milkweed.

Buttonwood. See Sycamore.

Cabbage (*Brassica oleracea*). The wild cabbage was found growing long ago in what is now England, and from there it has spread all over the world. Today it is an important vegetable grown throughout our country. It contains three of the vitamins which are recognized as useful in foods. The leaves, which form into a compact head, are eaten. There are green, red and purple varieties, also a savoy or wrinkled leaf variety. Sauerkraut is made from shredded cabbage, salted, packed and allowed to ferment slightly. Sauerkraut juice is used as a mild tonic.

Cacao (*Theobroma cacao*). A small tropical tree grown for its seed kernels or "beans" which yield cocoa and chocolate. The flowers and seed pods grow on the trunks and larger branches instead of on the smaller branches and twigs. It is necessary to shield the trees from the hot sun. This is done by planting shade trees next the cacao trees. Trees begin to bear at five years. Although the fruits appear throughout the entire year, they are harvested at regular seasons.

Cactus. Many forms of plants found in dry and desert areas. Leaves are temporary or much reduced in size and the stems are green and fleshy with hollow interiors filled with water. Usually cacti have stiff spines, although Burbank developed spineless varieties which are excellent stock food. Cacti often bear beautiful flowers, as the night-blooming cereus.

Calendula or **Pot Marigold** (*Calendula officinalis*). An annual producing orange and yellow flowers. As an old-fashioned herb, our grandmothers used the dried flowers to flavor soup, hence the name "pot marigold." Both single and double varieties are grown.

Calla Lily (*Zantedeschia aethiopica*). A house plant and in warm climates grown outdoors. The foliage is a rich dark green and the showy spathes pure white. Similar to the calla lily except in color is the golden calla (*Z. elliottiana*) with bright yellow flowers and leaves with white spots.

Calliopsis. See Coreopsis.

Camellia (*Camellia japonica*). An old-fashioned shrub, hardy in the south and grown indoors in the north. In color the flowers range from red, through pink to white. The wild flower is red and single, although in cultivation double varieties prevail. The large, shiny, laurel-like leaves, show off the blooms to good advantage.

Camomile. Medicinal plants of two kinds—the German (*Matricaria chamomilla*) and the Roman (*Anthemis nobilis*). The dried flowers are used in making a tonic. The dog's camomile or mayweed (*A. Cotula*) is a wild plant naturalized from Europe and a prolific weed. Its flower resembles a small daisy with white florets around a conical yellow disk.

Camphor (*Cinnamomum camphora*). The camphor tree is a relative of the cinnamon plant. It is a native of the Orient and has been introduced successfully into Florida. The tree is grown as an ornamental and as a windbreak. Camphor cuttings are distilled and the oil and gum collected and refined for the use of commerce.

Canada Thistle (*Cirsium arvense*). A troublesome weed which spreads rapidly by underground rootstocks. The plant occurs in Canada and in the northern half of the United States, and typically in patches instead of singly as the bull thistle with which it is often confused.

Candytuft (*Iberis* spp.). A garden flower of the mustard family. The white species is most common, but there are also crimson, purple and lavender kinds. The evergreen candytuft, bearing snowy white blossoms, is a perennial hardy and of easy culture; the leaves are dark green.

Canna (*Canna* spp.). A tropical-looking plant with sheathing leaves and red, pink, pale yellow to white flowers. The modern improved varieties are vastly superior to the old plant which was called "Indian shot" (referring to the very hard seed which must be filed before planting). The canna was introduced into our country from South America and the West Indies.

Caraway (*Carum carvi*). This biennial herb belongs to the parsley family. It grows to a height of a foot and a half to two feet. The seeds are used to flavor breads, cakes, sauces, soups, cheese and candy. An oil distilled from the seeds is used in perfumes and soaps. The seeds do not appear until the second year.

Cardinal Flower (*Lobelia cardinalis*). Brilliant vermilion, rarely rose to white, flowers an inch long borne in spikes on long leafy stems. This striking native wild flower prefers the lowlands and is often found along a stream. Its striking appearance has caused its wanton picking and it is now hard to find. It responds to cultivation and is easily grown from seed.

Carnation (*Dianthus caryophyllus*). A florist's flower ranking next to the rose commercially, the carnation has been grown in our country for 200 years since it was imported from southern Europe. It is a perennial and with its attractive form and wide range of handsome colors is a universal favorite.

Carrot (*Daucus carota*). A market garden vegetable of the parsley family grown for its edible root which is used for the table and also as a stock food, especially for dairy cattle. The color of the root ranges from a light yellow to reddish orange. Carrots rank high in nutrition and are especially valued for their vitamins. The Germans cut and dry the root and use it as a coffee substitute.

Cascara Sagrada (*Rhamnus purshiana*). A shrub, native to the western sections of our country, useful for its bark which contains a substance known as "purshiana," a laxative. The shrub is sometimes grown as an ornamental. Buckthorn (*R. cathartica*) is a close relative and is also grown as an ornamental in our eastern districts.

Cassava (*Manihot* spp.). A tropical member of the spurge family, now grown to some extent in our southern states. Tapioca comes from the starchy roots of cassava. In the tropics cassava bread is a staple food. The roots are often used as stock feed. In our country a sweet cassava is eaten as a vegetable.

Castor Oil Plant (*Ricinus communis*). Another member of the spurge family, an annual with great tropical-looking leaves of seven or more lobes. The plants grow to a height of from four to ten feet and are of easy culture. The plant is often grown as a screen for unsightly places. A native of Asia and Africa, the plant is now grown in most of the warmer countries for its well-known oil which is used medicinally and as a lubricant for delicate machinery.

Catalpa (*Catalpa bignonioides*). A quick-growing ornamental tree preferring damp soils. In early summer with large leaves and showy sprays of bloom the tree is very attractive. When not in leaf the tree is not beautiful. Characteristic of the tree are the long fruit pods which adhere to the branches throughout the winter and then split and disperse their winged seeds in the wind.

Catnip (*Nepeta cataria*). This herb, belonging to the mint family, is also known as "catmint." Its names refer to the fact that cats like to frolic in and chew the leaves. In Colonial days the plant was imported from its native European home and was used as a tea or a tonic. Tiny heads of small white flowers develop late in the summer.

Cat-tail (*Typha latifolia*). A wet area plant with characteristic sword-like leaves and brown cylinders of pistillate flowers. Flour for bread is made from the pollen and especially from the thick rootstocks.

Cauliflower (*Brassica oleracea botrytis*). A delicately-flavored variety of the cabbage species raised for its edible head which is composed of misformed flower stems and buds. Cauliflower is rather difficult of cultivation. A perfect cauliflower head should be uniformly snowy white and solid.

Cedar. The true cedar belongs to the genus *Cedrus* and is strictly an Old World tree. The so-called "American cedars" include white cedar or arbor vitae, the red cedar, Port Orford cedar and incense cedar. These cedars are valuable for posts in the air or in water. So-called "cedar apples" are the fruiting bodies of the fungus cedar rust.

Celery (*Apium graveolens*). A valuable market garden vegetable of the parsley family. It occurs wild in southern Europe and has been grown in cultivation for many years. The plant has a fibrous root, very short stem, or crown, and a cluster of long leaves which typically are blanched and eaten as a relish or in salads or cooked.

Century Plant (*Agave americana*). This member of the aloe family is found growing in the desert but responds readily to cultivation provided the soil is not too rich and there is not too much water. One does not have to wait a century for the plant to bloom, but the time is usually twenty years or more. Flowers are borne in clusters on a high stem and are white or greenish-white in color. The plant generally dies after blooming and maturing seeds, but suckers arise from the base of the old plant.

Cherry. A tree of the genus *Prunus*, grown for its edible fruit. In the Far East the cherry is grown as an ornamental and in Japan the native species, *P. pseudo-cerasus*, has been cultivated for beauty for centuries. Cherries range in size from the diminutive sand cherry to the towering tree of the wild black cherry. Other wild species are the red cherry and the chokecherry. Two orchard cherries have been developed, the sweet and the sour.

Chess or **Cheat** (*Bromus secalinus*). A weed of the grass family, probably imported in early days from Europe. It is not a degenerate wheat or rye, but is a close relative of the brome grass. In some districts chess is grown as a hay crop under the name of "Arctic grass."

Chestnut and **Chinquapin** (*Castanea dentata* and *C. pumila*). Our native chestnut and its close relative, the chinquapin, have relatives in the sweet chestnut of Europe and the Japanese species. The American chestnut is a splendid shade tree and produces desirable nuts and valuable wood. The misfortune is that the chestnut-tree blight, caused by a fungus, has destroyed so many of these noble trees. Chinquapins are smaller trees and produce smaller, but good, nuts and wood that is used for posts and railroad ties.

Chickweed. All over the earth the common chickweed (*Stellaria media*) has made its way and the only use man has found for it is to feed caged birds. It is occasionally fed to chickens. This delicate-appearing weed is really one of the hardiest and its small star-like flowers and seeds are produced at almost any season of the year. Two other chickweeds, likewise members of the pink family, are the mouse ear chickweeds—the common and the field species (*Cerastium vulgatum* and *C. arvense*). These chickweeds are not as serious pests as the first described.

Chicory (*Cichorium intybus*). Imported from Europe, this relative of the endive and dandelion has become in our country a troublesome meadow weed. It has bright blue flowers, sometimes pinkish or white, and a long, heavy taproot. The root, dried and powdered is used as a substitute and as an adulterant for coffee. The blanched leaves are eaten, especially by the French, as a salad. French endive, or Witloof chicory, is a variety of chicory in which the leaves have been made into a solid head, which is used as a winter salad.

China Aster. See Aster.

Chrysanthemum (*Chrysanthemum hortorum*). Although the word Chrysanthemum means "golden flower," this most important of the late blooming garden flowers appears in other colors as well as yellow. The hardy garden varieties are from one-half inch to two inches in diameter, sometimes single and again semi-double or double. To raise the enormous blooms which the florist displays requires expert and special greenhouse attention. By pinching back the plants during the growing season bushy plants and many buds are produced. Among the larger greenhouse chrysanthemums are the double quilled, the double with expanded rays and the reflexed.

Cinchona (*Cinchona officinalis*). This shrub or tree is a native of the slopes of the Andes. Its so-called "Peruvian bark" yields quinine. Formerly the main source of quinine was these wild trees of South America, but today the plant is cultivated in India and other parts of the Far East and little quinine is made from wild barks. In harvesting the bark vertical strips are removed and the wounds heal allowing the taking of additional strips each year. Sometimes the plants are cut down and new bark secured from the development of sprouts at the base. The use of quinine in the treatment of fevers was made known to the early Spanish explorers in South America by the native Indians.

Cinnamon (*Cinnamomum zeylanicum*). A tree belonging to the laurel family. As the name *zeylanicum* suggests, the plant is a native of Ceylon where much of the best cinnamon is raised today. The most valuable product is the cinnamon bark, which is used as a spice in cookery and medicinally as a stimulant and cordial. In cultivation the plant is continually cut back to a stump and sprouts are allowed to develop. From these two-year-old shoots the bark is taken and dried to form the cinnamon bark of commerce. The entire plant is sometimes used for its oil.

Clematis (*Clematis* spp.). A genus of the crowfoot family, consisting of more than 150 species. Many species are climbers. The best known is the native Virgin's bower (*C. virginiana*) which bears white and greenish flowers in loose clusters. In the autumn the long, feathery plumes attached to balls of seeds reveal the reason for another name, "old man's beard." The imported Japanese white clematis (*C. paniculata*) is very popular for planting on porches. The purple *C. jackmanii* is also a popular planting species.

Clover (*Trifolium* spp.). The true clovers all belong to the genus *Trifolium*, a word meaning "three-leafed," although there are many other so-called clovers, as sweet clover, prairie clover and burr clover. There are more than 300 species of *Trifolium* known in various parts of the temperate zone. In our country four important clovers are cultivated—red, white, crimson and alsike. Clovers are used as a forage crop, especially for cattle. They are also used in rotation as a soil-improving crop. Clovers thrive in cool, moist climates and cannot withstand prolonged heat or drought.

Cloves (*Caryophyllus aromaticus*). An important spice consisting of the dried flower buds of a tropical tree belonging to the myrtle family. The name "cloves" comes from the French word *clou*, meaning "nail," and refers to the appearance of the dried bud. The clove tree attains a height of from thirty to forty feet. The buds are picked by hand, a tree yielding from five to seventy-five pounds of the spice. The cloves are rich in oil and unscrupulous growers sometimes remove the oil, thus lessening the aroma of the cloves. The oil is used in soaps, candies, perfumes and medicines.

Cockle (*Lychnis githago*). A weed which infests wheat and other grain fields, especially common in the Central and Western States. It has been called the "corn cockle," from the Old World name of wheat. The purple flowers appearing from July to September, present a striking sight in grain fields. The seeds are poisonous but modern milling methods have practically eliminated them from flours.

Cockscomb (*Celosia* spp.). A border plant grown for its showy flower heads of crimson and ranging to orange and creamy white. The flower heads grow in great clumps bearing some resemblance to a rooster's comb, hence the common name. The crested and the plumed or feathered are the two leading species grown in the flower-garden.

Coconut Palm. See Palm.

Coffee (*Coffea arabica*). Coffee growing wild is said to have been noted in Arabia in the thirteenth century. It was discovered in Abyssinia at an early date. The coffee plant is a small tree of the madder family. It produces fragrant white flowers which after about seven months, ripen into crimson cherry-like fruits which open and disclose two flat-faced coffee beans. After being properly cured these beans become the coffee of commerce, which has become one of the world's leading beverages. An alkaloid, caffeine, is the active stimulant in coffee.

Columbine (*Aquilegia* spp.). A genus of which more than twenty species occur in America. This flower bears five tubular petals ending in horn-like honey sacs which suggested to Linnaeus the talons of the eagle, hence the name *Aquilegia* from *aquila* the eagle. Bailey states that the name is derived from *aquilegus* ("water bearer") and refers to the shape of the flower. The common wild columbine is a red flower, yellow inside, blooming in rocky areas and rich woodland from April to July. The blue columbine is a native of our Western States and has been chosen as the state flower of Colorado. There are also yellow and white columbines.

Conifers. Trees or shrubs producing cones which contain seeds, hence the name which means "cone-bearers." These plants belong to the order *Coniferales* and are the main, living group of the gymnosperms and the only group native to North America. One great group of the conifers is the pine family, including besides the pines, the firs, spruces, hemlocks, cedars, larches, junipers, cypress and those oldest of all living things, the redwoods. Another group of conifers is the yew family.

Coreopsis or **Tickseed** (*Coreopsis lanceolata*). The name *Coreopsis* means "bud-like" and refers to the seed, and the name "tick-seed" is likewise fitting. The large daisy-like flowers are desired for picking and give a brilliant dash of yellow to the flower garden all through the summer. Calliopsis (*C. tinctoria*) is a showy annual with flowers ranging from red and maroon to brown and yellow.

Cork Oak (*Quercus suber*). An oak, native to the countries bordering on the Mediterranean Sea, grown for its spongy bark, the cork of commerce. The tree grows to a height of not over forty feet but attains a large diameter, sometimes of four feet. The outer bark is removed about every nine years without injury to the health of the tree. The life of the tree may be 150 years or more. Although introduced into our country, cork oaks have never been grown here on a commercial scale. The principal supply comes from Spain and Portugal.

Corn (*Zea mays*). A member of the grass family and the leading American farm product. Corn is a native of the New World, coming probably from the high tablelands of southern Mexico. Some scientists maintain that it was developed from the Mexican plant *teosinte*, which at least is a close relative. Corn was the chief source of food among the Indians. Several hundred varieties of corn are grown ranging from plants two feet tall to huge thirty-foot stalks, but there are six principal types—dent, flint, flour, sweet, pod and pop corn.

Cornflower (*Centaurea cyanus*). A garden flower with fringed trumpets of blue, pink or white. It is often called "bachelor's button," although this name is applied to various other flowers as well. This plant will seed itself and reappear year after year.

Cosmos (*Cosmos bipinnatus*). A late-blooming garden flower which grows five to ten feet high and completes most of its growth before blooming. This annual prefers not too rich ground and abundant sunshine. The flowers are red, pink or white. Both single and double varieties are grown.

Cotton (*Gossypium* spp.). Cotton includes all the plants of the genus *Gossypium*, of the mallow family, native to the tropics. The origin of cotton is unknown, but its use doubtless antedates history in China, Japan and India. Wild cotton grew to a height of fifteen feet or more, but in cultivation the plant is kept to a more convenient height for picking the fiber. The large handsome flowers are of various colors. The seeds occur in pods or bolls, which are filled with the fluffy white fiber from which the cotton of commerce is made. Oil is derived from the seeds. Many species of cotton are known but only a few are agriculturally important. There are two main groups—the American and the Asiatic. The former includes upland, sea-island and Peruvian cotton. Most of our cotton is upland. Among the Asiatic cottons are Bengal and Indian.

Cottonwood. See Poplar.

Cowpea (*Vigna sinensis*). This annual is one of the important legumes of the southern part of our country. It is a native of Asia and has been known and cultivated at least since Roman times. This close relative of the bean is extensively used as a forage plant and as a green-manure crop. For table use white-seeded and black-eyed varieties of the seed are used.

Crab Apple. See Apple.

Crab Grass (*Digitaria sanguinalis*). An annual usually classed as a weed, although it is sometimes used as a forage plant. The plant stems spread out and take frequent root, making the grass hard to eradicate. Atop the stem are from three to six spikes which bear flowers and seed which mature to a reddish or purplish color.

Cranberry (*Vaccinium macrocarpon* and *V. oxycoccus*). A water-loving trailing shrub of the heath family grown principally in northeastern sections of our country and in Canada. The small, red, acid fruit is esteemed for cooking uses. The flower and the curved stalk on which it hangs, resemble the head and neck of a crane and is said to have been responsible for the name which was altered from "crane-berry" to "cranberry." There are two leading species, the small-fruited and the large-fruited.

Cress. A group of salad plants of the mustard family. Water cress flourishes when both roots and stems are grown under water. Upland cress and garden cress, or peppergrass, are grown in gardens.

Crocus (*Crocus* spp.). Early-blooming spring flowers grown from corms planted in the autumn. The flowers are purple, lavender, white and yellow. The autumn crocus (*Colchicum autumnale*), although planted at the same time as the spring blooming flowers, does not bloom until September or October. The most common flowers are the lilac-colored.

Cucumber (*Cucumis sativus*). This trailing annual of the gourd family has a long history, extending back for at least 3,000 years to Asia where it was probably a native of India. The fleshy oblong fruit is sliced and eaten green and it is also used for pickling. The plant is tender and requires warmth and sunshine.

Currant (*Ribes* spp.). A shrub grown for its small acid fruits which occur in clusters. The most important species, the black and the red, are natives of northern Europe where they have been grown since the sixteenth century. Native American species which have been cultivated to a limited extent are the wild black, the wild swamp and the Buffalo or golden currant. On the Pacific coast an ornamental, the wild California flowering currant, is being raised for its handsome yellow flowers.

Cyclamen (*Cyclamen persicum*). A florists' plant with beautiful foliage and flowers ranging from pink to dark rose, often with a dash of another color, most frequently purple. Other forms of flowers are fringed or crested. The blossoms will last all winter. The cyclamen is a member of the primrose family.

Cypress (*Cupressus* spp.). A genus of conifers with graceful leaf-sprays and small, erect woody cones. All are ornamental and some are very valuable for their wood. The European cypress (*C. sempervirens*) is noted in literature and is often seen in cemeteries and in hedges. The Monterey, or cypress of Mexico, is native to a few miles of coast near Monterey Bay in California, where its form is gnarled and grotesque. In cultivation this species (*C. macrocarpa*) develops into a shapely tree. The bald cypress (*Taxodium distichum*) of the South is the one member of the cypress group that is deciduous. It grows in wet places and develops swellings at the base of the trunk known as "cypress knees." The wood is very valuable and under water is almost imperishable.

Daffodil. See Narcissus.

Dahlia (*Dahlia* spp.). A perennial, native to Mexico, and now grown widely as a garden flower for cutting. The wild plant has red flowers with yellow centers but the cultivated varieties are of every color except blue and scarlet. The plant is grown from tuberous roots which have eyes at the stem end. The plant grows two to six feet high.

Daisy. The common oxeye daisy (*Chrysanthemum leucanthemum*) is a native of Europe that has become so thoroughly at home in our country that it is now regarded as a weed. It is a perennial with short, thick underground stems. It is a handsome flower and has been chosen as the official floral emblem of the American Legion. There are many other daisies. In England there is the dwarf rose, pink or white garden daisy (*Bellis perennis*). The Shasta daisy is larger than the oxeye. The pink daisy (*Pyrethrum*) is red, pink or white and often doubled. Other daisies include the giant, the Paris and the Swan River. The Michaelmas daisy has already been mentioned under Asters.

Dandelion (*Taraxacum officinale*). A common lawn weed widely distributed over the northern United States and Canada. The name, meaning "tooth of the lion" is derived from the jagged edges of the leaves. Bright yellow flowers are borne on stalks which rise from a rosette of leaves. The tender young leaves are sometimes used as a salad or cooked as greens. Bees feast on the flowers in spring.

Date Palm. See Palms.

Dill (*Anethum graveolens*). A biennial herb of the parsley family, a native of southern Europe, growing from two to three feet high. It is cultivated for its seeds which are used in soups and sauces and for flavoring pickles. The seeds yield an oil which is used in soaps and medicinal preparations.

Dock (*Rumex crispus* and *R. obtusifolius*). Both of the two important docks, the narrow-leaf or yellow (*R. crispus*) and the broad-leaf (*R. obtusifolius*) are perennials common in meadows and pastures and sometimes in alfalfa fields. The narrow-leaf species may be eaten as greens. In Colombia the broad-leaf dock is used for grazing. Usually the docks are regarded as troublesome weeds and the seeds are often present as impurities in the seed of clovers, alfalfa and timothy.

Dodder (*Cuscuta gronovii*). One of its names, "strangle-weed," describes this strange plant which is a parasite without green leaves. This twining yellowish or reddish vine fastens itself to many agricultural plants, as clover or alfalfa, and by means of sharp suckers, or haustoria, penetrates the stems and extracts nourishment. Clusters of little pink flowers develop from July to September.

Dogtooth Violet or **Yellow Adder's Tongue** (*Erythronium americanum*). Not a violet at all but a member of the lily family, the young shoots of early spring do resemble a snake's tongue. This little plant with its russet yellow flowers is one of the earliest harbingers of spring in all the eastern United States, especially in moist woodlands or thickets.

Douglas Fir (*Pseudotsuga Douglasii*). Not a true fir but botanically between the firs and the hemlocks, this giant tree is also known as the Douglas spruce. The lumberman calls the lumber "Oregon pine," and it is one of the best known Western lumber trees. In the interior, where the tree grows smaller, it is called "red pine." This great conifer typically stands straight and without a limb almost 200 feet and has a top another hundred feet above the clear trunk. Such a tree has enough lumber to build a dozen houses.

Dutchman's Breeches (*Dicentra cucullaria*). A member of the fumitory family, a wild flower with delicate green foliage and dainty heart-shaped flowers of white tipped with yellow hanging tremblingly on slender stems. The plant is found in rich leafy mold in woodland areas south to Carolina and west to Nebraska.

Easter Lily. See Lily.

Ebony. Commercially, ebony is the name applied to the black heartwood of various trees native to the tropics. The trees producing ebony are frequently two or more feet in diameter. Ebony wood is hard and heavy and takes a high polish. It is used for boxes, ornaments and veneers in cabinetwork. The native American persimmon yields a fair grade of ebony wood.

Edelweiss (*Leontopodium alpinum*). A small Alpine of the aster family. In Switzerland, where it is becoming rare on account of the zealous collectors who seek the beautiful silvery-white flowers, it is now protected by law. Edelweiss is now being cultivated in our country in gardens.

Eggplant (*Solanum melongena*). A tropical annual of the nightshade family, grown extensively as a garden vegetable for its egg-shaped fruits. The plant is a native of India but is now grown in America, especially in the warmer areas. The fruits are light-colored to dark purple and black. In America the dark varieties are preferred.

Elder (*Sambuous* spp.). An ornamental shrub of the honeysuckle family, becoming in some species, as in the Mexican elder (*S. mexicana*), a tree. The common elder (*S. canadensis*) is a native of America particularly successful in wet soils. It bears clusters of white flowers and purple berries. Elderberry wine is made from the berries. The elders will grow in poor soil and offer an attractive covering for thin land. The red-berried elder (*S. racemosa*) is a native of America and with its good foliage and fine red fruits makes a favored ornamental. Elderberries are also used in medicine and in making perfumes.

Elecampane or **Horseheal** (*Inula helenium*). A tall roadside plant bearing large yellow flowers in late summer. It is a native of Europe and was brought to America for the supposed medicinal value of its

fleshy roots, which were formerly much used as a tonic and expectorant. It was also used as a medicine for horses, hence its name "horseheal."

Elm (*Ulmus* spp.). A valuable shade and lumber tree represented by a number of native species. Others are native to the Old World. The English elm (*U. campestris*) has been extensively introduced in the eastern United States. The white or American elm (*U. americana*) is a tall, graceful native species, common east of the Rocky Mountains. The slippery or red elm (*U. fulva*) has red wood and beneath the bark of the young shoots is a sweet, delectable substance that boys like to chew. The rock or cork elm (*U. Thomasi*) is a large northern species with very hard wood much sought by wheelwrights. The name "cork" refers to the corky bark of this species. The wahoo or winged elm is a southern species, small and dainty.

Endive (*Cichorium endivia*). A salad plant related to chicory, native to Europe but now grown in America. The curly, fringed or cut leaves are often tied together and blanched in the head to remove the bitter taste.

Eucalyptus (*Eucalyptus* spp.). A genus of the myrtle family including more than 300 species. The trees are native to Australia but have been planted around the world in warm areas. In southern California the blue gum (*E. globulus*), a very rapid grower, has been planted extensively as a windbreak for citrus groves. The eucalyptus grows tall and usually with a single stem. The bright leathery foliage combines to make a very graceful tree and one desirable for street planting. Eucalyptus oil is used in medicine.

Euphorbia (*Euphorbia* spp.). Any of the spurges, constituting a large genus of plants bearing attractive flower-like leaves and unusual tiny flowers and containing a milky juice. The flowering spurge (*E. corollata*) is a native of sandy areas in the eastern United States. It bears white flowers. Another species is commonly known as "snow-on-the-mountain" (*E. marginata*). It has attractive flower-like light green leaves and very small flowers.

Evening Primrose (*Oenothera biennis*). A field and roadside weed bearing fragrant, yellow flowers which open at evening. In late summer the flower stays open during the day. It is common throughout North America. The root and the tender crown leaves are edible.

Everlasting Flowers. Strawy annual flowers which are kept as decorations through the winter. Blooms should be cut before fully opened and dried by hanging upside down. Among those useful as everlastings may be included *Acroclinium*, *Helichrysum* (strawflower), *Rhodanthe* and *Xeranthemum* (immortelle).

Fennel (*Foeniculum vulgare*). A garden herb, native to southern Europe and now cultivated or found wild in many parts of the world. It is a member of the parsley family. In cultivation it is used, especially by the Italians and the French, as a seasoning and a salad, while the oil of the plant is used in soaps and perfumes. Fennel often becomes a troublesome pasture weed.

Ferns. In plant life the ferns are a group a step higher than the mosses. Ferns are the highest type of flowerless or seedless plants. There are over 6,000 ferns known, ranging from small climbing plants to tree-like plants fifty feet high. Reproduction is by means of spores instead of seeds. The leaves are properly called "fronds"; the stalks, "stipes," and the underground stems are known as "rhizomes." Ferns occur in the greatest variety and profusion in the moist soil of the tropics. Among the wild ferns are the maidenhair, Christmas, cinnamon, ostrich, royal and walking ferns. House ferns of importance are the Boston, dagger, maidenhair and holly ferns.

Fig (*Ficus* spp.). A large genus including the rubber plant (*F. elasticus*). The fig of commerce, which is grown for its edible fruit is *F. carica*, a native of Asia and now successfully imported and cultivated in southern California. The pear-shaped fruit ranges from green to blue-black and is eaten raw or dried. The banyan tree of India is another member of this genus. One of these remarkable trees with its aerial roots sometimes covers an acre or more of ground.

Fir (*Abies* spp.). This genus of evergreen trees contains pyramidal forms and needle leaves as do the spruces but differs in holding the ripe cones, which are borne near the top of the trees, erect. The firs have bark blisters which contain a resinous substance used in medicine and in the arts. The balsam fir (*A. balsamea*) is the typical Christmas tree and yields the Canada balsam of medicine. The fragrant leaves are often used to stuff pillows. Another balsam fir is *A. Fraseri*, a favored ornamental. The red fir (*A. magnifica*) of the West is a magnificent tree, often reaching a height of over 200 feet and a trunk diameter of as much as seven feet.

Flax (*Linum* spp.). A plant grown for its fiber and seed since ancient times, its origin being probably in Egypt or China. The common species (*L. usitatissimum*) is an annual which grows from one to over three feet in height, with narrow leaves and handsome flowers, usually blue, but white in some varieties. Fiber flax and seed flax are different cultivated developments of the same species. The same plant does not produce both good fiber and good seed. Linen cloth, thread and rope are manufactured from the fiber. The flat, brown seeds are commercially known as "linseed" and yield linseed oil, which is used in paint and varnish and in the manufacture of linoleum and printer's ink.

Fleur-de-lis. See Iris.

Forget-me-not (*Myosotis* spp.). A garden and wild flower of the borage family. The flowers are blue, pinkish or white with yellow eyes. A native of Europe and Asia, the forget-me-not is now found wild in the eastern United States where it prefers brooksides and low meadows. The flower has long been held as an emblem of friendship. The best known species is *M. scorpioides*.

Forsythia or **Golden Bell** (*Forsythia* spp.). A spring garden shrub which derives its name from its graceful bell-shaped flowers which appear before the leaves. The drooping forsythia (*F. suspensa*) is desirable for growing on steep terraces.

Four-o'Clock (*Mirabilis jalapa*). A garden flower imported from South America, also known as "marvel of Peru." The flowers open about four o'clock in the afternoon and stay open all night. It is a tender perennial with roots which may be stored indoors over winter. It is usually grown as an annual. The flowers are trumpet-shaped and in gay shades of red, yellow and white and striped.

Foxglove (*Digitalis* spp.). A stately garden flower three to five feet tall and bearing large, tubular ma y-colored flowers in spikes. The foxglove which grows along roadsides in England is famed in poetry.

Foxtail grass. A name applied to various northern grasses, mostly of wet soils. A cultivated species, the meadow foxtail (*Alopecurus pratensis*), is important in Europe but not in America. Two common species of weedy foxtails are found in our country, the yellow (*Setaria glauca*) and the green (*S. viridis*). These are injurious in grain fields.

Freesia (*Freesia refracta*). A winter-blooming house plant propagated from a bulb. The colors of the flowers include white, yellow, lavender and pink.

Fuchsia (*Fuchsia speciosa*). A house plant now grown principally in greenhouses. This native of South America is easily cultivated and is unexcelled for decoration. The plant has shiny leaves and brilliantly colored flowers in purples, reds, white and combinations.

Fungi. A thallophytic group of plants including the molds, rusts, smuts and mushrooms. They contain no chlorophyll and reproduce by spores. Since fungi cannot manufacture their own food, they are parasitic (living on, in or with another living organism, the "host") or saprophytic (living on dead or decaying organic matter). The fungi comprise a large number of classes, orders and families. Many of the mushrooms are edible, while others are poisonous. Many of the molds, rusts and smuts are highly injurious to their host plants. Many saprophytic fungi are beneficial.

Gaillardia or **Blanket Flower** (*Gaillardia aristata*). This native wild flower of the Western states is grown throughout the country as a garden flower. Some are annuals; others are perennials. The rather scant foliage is atoned for by the showy, daisy-like flowers of reds, yellows and browns.

Gardenia (*Gardenia* spp.). An attractive flower resembling the camillia, but more fragrant. The yellow bloom is a popular florist's flower. The cape jasmine, a hardy outdoor flower in the South and a greenhouse plant in the North, is a gardenia.

Garlic (*Allium sativum*). Native to southern Europe, garlic has been grown since ancient times and is mentioned in the Bible. The odorous bulbs are used, especially by the people of southern Europe, as a flavoring in cooking and the oil is used medicinally. In America the plant must be ranked as a troublesome weed, especially in wheatfields.

Gentian (*Gentiana* spp.). A large genus of blue, sometimes yellow-flowered wild flowers. The beautiful fringed gentian (*G. crinita*) responds to careful cultivation in the garden. It is now almost extinct wild. The yellow gentian (*G. lutea*) and the soapwort gentian (*G. saponaria*) are used medicinally for their roots. The closed or bottle gentian (*G. andrewsii*) is also cultivated in gardens. It has a peculiar mass of flowers shaped like a bottle.

Geranium. The cultivated house and garden flowering plants commonly known as geraniums, really are members of the genus *Pelargonium*. The true geranium is a wild flower. The common species (*Geranium maculatum*), also known as cranebill, is found in woods and shady roadsides and produces rose-purple flowers from April to July. The root is used medicinally. *Pelargonium* is a popular house plant, as it will grow in a warm, dry room with a minimum of attention. It should receive sunshine. The soil should not be too rich or the plant will go to foliage and produce few if any blooms. The cultivated geraniums are derived from species originally brought from South Africa.

Ginger (*Zingiber officinale*). A herbaceous plant which has been cultivated in its native land, Asia, for many hundreds of years. It is now grown extensively in the West Indies, especially in Porto Rico and Jamaica. The plant grows from an underground stem. The leaves and flowers are on different stalks. After flowering, the stalks wither and the pungent, aromatic rootstocks are dug and used, after grinding, as the ginger of commerce. Preserved ginger is made of the rhizomes while they are young and tender. The so-called "wild-ginger" (*Asarum canadense*) is an altogether different plant.

Ginkgo (*Ginkgo biloba*). A compact, erect tree, native to Japan, much used as a shade tree in cities where space is limited. The peculiar, fan-shaped deciduous leaves of the ginkgo, or maidenhair tree, are signs of identification. The fleshy fruits have an unpleasant odor. The Chinese roast and eat the kernels.

Ginseng (*Panax* spp.). A perennial plant native to China, esteemed very highly by the Chinese who use the roots as a medicine. The Chinese species (*P. ginseng*) is grown to a limited extent, but it is difficult to cultivate. The American species (*P. quinquefolium*), which grows wild in the eastern half of the United States and in Ontario and Quebec, is now being sold extensively to the Chinese. Although the root probably has some medicinal value, the Chinese mix much superstition with its use and pay fabulous prices for roots which bear resemblance to the shape of the human body.

Gladiolus (*Gladiolus* spp.). A genus of handsome garden plants of the iris family. They are propagated from corms, which are planted in the spring. The flowers vary from red to yellow to white through a range of delicate pastel shades.

Gloxinia (*Sinningia speciosa*). A handsome greenhouse plant with large, bell-shaped flowers in a variety of colors with dotted and blotched effects. Plants are propagated both from seed and tubers.

Godetia (*Godetia* spp.). A garden flower, a close relative of the evening primrose. The flowers are beautiful with large satiny petals and range in color from deep red to white. A popular godetia (*G. amoena*) is called the "farewell to spring."

Goldenrod (*Solidago* spp.). A perennial American wild flower embracing sixty species belonging to the composite family. The small heads of yellow flowers appear in autumn and brighten with a profusion of color, forests, fields and roadsides. The plant responds to cultivation and makes a good garden border. The goldenrod is often falsely accused of causing hay fever (see Ragweed).

Goldenseal (*Hydrastis canadensis*). A small herb, native to the eastern half of the United States, south of New England. It belongs to the crowfoot family and is a close relative of the larkspur. It is important for the medicinal value of its rootstocks which are used extensively both in the domestic drug trade and for export. The name is derived from the scars or "seals" on the root caused by the dying off of the stem at the end of autumn. A single greenish white flower appears in April but soon drops off. The bright red fruit resembles a raspberry. The rootstocks are yellow. The Indians formerly used the yellow juice as a war paint.

Gooseberry (*Ribes* spp.). A bush fruit of the saxifrage family and a close relative of the currant. The plant flourishes in the cooler temperate areas of our country. The gooseberry fruit is green, oval and sour until thoroughly ripe, when it turns to a light purple and becomes sweet. Both American and European varieties are cultivated in our country.

Gourd. Any of a number of plants related to pumpkins and melons, cultivated for their vines and for their fruits. The fruits often have hard shells and when dried and emptied of their pulp are sometimes used for dishes or drinking utensils.

Grape (*Vitis* spp.). An ancient vine fruit, mentioned in the Bible and cultivated as early as the Bronze Period. Grapes have been used most extensively for their juice and secondarily as fresh fruit and raisins. Grape culture in the United States embraces three types. On the Pacific slope the Old World, or vinifera varieties, rich in sugar and with easily detached seeds, are grown. This region produces half the grape crop of our country. The northern part of the country, east of the Rockies, produces the Labrusca or "slip-skin" varieties. The seeds are not easily removed from this type of grape. In the South Atlantic and Gulf states, Muscadine varieties, with large fruits and large seeds, are grown. Small seedless varieties of Old World grapes are preserved under the name "currants."

Grapefruit (*Citrus grandis*). A large fruit of a small tree of the citrus family, native of the Far East where it has been cultivated for 2,000 years. Horticulturally, the fruit is correctly known as the "pomelo." The name "grapefruit" is derived from the fact that the fruits are borne in clusters resembling bunches of grapes. In recent years the tree has been introduced and extensively grown in Florida and California, and the fruit is in high demand as a breakfast fruit and in salads. The shaddock is a tree and its fruit botanically identical with the grapefruit but horticulturally different. The fruit is coarse and practically inedible.

Grasses. A name used botanically to include the members of the *Gramineae* family, usually with hollow stems, alternate leaves and bearing fruit known as "grain." True grasses include timothy, millet, sugarcane, wheat, rye, oats, corn and barley. Inaccurately, the grasses are said to include all forage plants.

Guava (*Psidium guajava*). A tropical shrub or small tree of the myrtle family with fragrant white flowers and a yellow, mildly acid fruit about the size of a hen's egg. The color of the flesh is white to deep pink. A jelly made from the fruit is important in commerce. The fruit is also eaten fresh and in jam. The guava is native to Mexico and the country south to Peru. It has been introduced into California and Florida.

Gum. Any of various tasteless, shapeless substances exuded by plants and which are soluble or soften in water. Gum arabic is a red to straw-colored gum obtained from either of two acacias. Cherry trees and plum trees often exude a gum that is used in stiffening straw goods.

Gypsophila or **Baby's Breath** (*Gypsophila* spp.). A garden and florist's plant with numerous tiny white to light pink flowers borne on feathery stalks. Although usually grown as a perennial, there is an

annual species (*G. elegans*) which blooms within six weeks of sowing seed. The flowering sprays are principally used in bouquets.

Hackberry (*Celtis* spp.). A tropical and temperate zone tree related to the elm. Species native to North America are found east of the Rocky Mountains. They attain the greatest size in the Mississippi Valley where they often reach a height of 125 feet. The bark carries thick ridges set with little elevations or "hacks." The berries often hang on during the winter and are much sought by birds. The common hackberry (*C. occidentalis*) is an ornamental shade tree and easily transplanted. The sugarberry (*C. mississippiensis*) is a favorite street tree of the Southern States. The European nettle tree (*C. australis*) bears a sweet fruit and is said to have been the "lotus" of classical literature.

Hawkweed (*Hieracium* spp.). This wild flower which has become a troublesome weed is named after *hierax*, the hawk, because people used to think hawks swooped down to sharpen their eyesight with leaves of the plant. The orange hawkweed, or devil's paintbrush (*H. aurantiacum*), is a weed in pastures of the northeastern United States. The yellow hawkweed (*H. pratense*) is a pest in the states of Virginia, West Virginia and western North Carolina.

Hawthorn (*Crataegus* spp.). Shrubs and trees of the rose family and relatives of the apples and plums. The genus is large and most American species occur east of the Rocky Mountains. The hawthorns are usually spiny and bear clusters of white to pink flowers. The small, applelike fruits are most frequently red, sometimes yellow, blue or black. The English hawthorn (*C. oxyacantha*) has long formed hedgerows in England. The scarlet, black, and red hawthorns are prominent American species.

Hazelnut (*Corylus* spp.). A small genus of shrubs and small trees of the birch family. The hazelnut is a toothsome, rich, oily seed, commonly sold around Christmas time. The common hazelnut (*C. americana*) is found from Kansas eastward. The beaked hazelnut is found in the northern part of our country, west to Kansas. A California species, *C. californica*, is native to the Pacific coast. The filbert is the nut of the European species, *C. avellana*.

Heliotrope (*Heliotropium* spp.). Herbaceous shrubs of the borage family, used mainly as a bedding and window plant. Originally the flowers were purple but now there are shades ranging from purple to white. The more the plant is cut back, the more it blooms.

Hellebore, American (*Veratrum viride*). A poisonous plant of the lily family, widely distributed over North America. It sometimes grows to a height of seven feet and is noticeable with its large, shining plaited leaves and yellowish or whitish-green flowers in spike-like panicles. All of the plant is more or less poisonous and the roots especially so. The roots are used in medicine. Other hellebores (*Helleborus* spp.) are early blooming perennials of the buttercup family.

Hemlock (*Tsuga* spp.). A genus of evergreen trees represented in North America by four species. This graceful pyramidal conifer is often grown in damp places as an ornamental. The common hemlock (*T. canadensis*) occurs from Nova Scotia to Alabama and west to Minnesota. The wood is used for lumber, but it is splintery; the bark is valuable for its tannic acid, used in tanning leather. The western hemlock (*T. heterophylla*) of the Western States is a large tree. Its lumber is valuable and the bark is used for tanning.

Hemp (*Cannabis sativa*). A cultivated fiber plant of the mulberry family, native to Asia, dating back to the twenty-eighth century B.C. The greenish-yellow flowers are small and inconspicuous. The staminate and the pistillate flowers are borne on different plants. Hemp grows to a height of from four to twenty feet. Hemp is extensively grown in Asia and Europe. It was introduced into America by the early colonists, but in recent years its production has declined, due to the increase in competitive fibers. In the United States hemp is used for twines, cordage and coarse threads.

Henequen (*Agave fourcroydes*). A fiber plant of the amaryllis family, used in making binder twine. It is cultivated in Mexico and the West Indies. The fiber is obtained from the long gray-green leaves.

Hepatica (*Hepatica triloba*). A forest and hillside wild flower of the crowfoot family. It blooms even under the snow of late winter and is an early announcer of spring. The flowers range from pale blue to pinkish or white. Because of the resemblance of the leaves to the human liver, the hepatica is commonly known as "liverleaf."

Hibiscus. A genus of large-flowered plants of the mallow family. The swamp rose mallow (*H. moscheutos*) is found in brackish marshes, but it will grow in the garden. Its large rose pink to white flowers are sometimes ten inches in diameter. This species is a hardy perennial grown chiefly along the Atlantic seaboard. The Rose of China (*H. rosasinensis*) has a showy scarlet flower which stains black. It is used by Chinese married women to stain their teeth, and in the West Indies for blacking shoes.

Hickory (*Carya* spp.). All the hickories are native to the eastern half of North America and have been propagated in other sections. The tough, close-grained wood is valuable in making implements and tools and provides excellent fuel. The nuts of many of the species are prized as food rich in protein. The shagbark or shellbark hickory (*C. ovata*) is so named from its ragged looking trunk. The nuts of this species are the familiar hickory nuts of commerce. A larger shell but not materially larger kernel is produced by the big shellbark (*C. laciniosa*). The pecan (*C. pecan*) is a hickory which sometimes attains a height of 170 feet. It produces the best nut of any of the genus, and, by breeding, a number of desirable thin-shelled varieties have been developed. The home of the pecan is the Mississippi Valley. Among the hickories with undesirable nuts are the mockernut (*C. alba*), the pignut (*C. glabra*) and the bitternut (*C. cordiformis*). These latter trees are important for their lumber, however.

Holly (*Ilex* spp.). A large genus of trees and shrubs scattered over the world. The European holly (*I. aquifolium*) and the American holly (*I. opaca*) are popular as Christmas decorations. The red berries and the glossy green leaves are very attractive. The European holly is used for hedges and borders. The American species with its beautiful white wood is sought by the wood engraver. Two interesting species of Paraguay holly are known as "maté." The leaves are brewed into a tea known as "yerba maté," widely used by South Americans.

Hollyhock (*Althaea rosea*). A tall unbranching garden plant of the mallow family with flowers ranging from rose and purple to white and yellow, both single and double. Although usually perennial, annual varieties have been developed. In Egypt the leaves are used in cookery.

Honey Locust. See Locust.

Honeysuckle (*Lonicera* spp.). A large genus of shrubs and climbing plants of the honeysuckle family, noted especially for the fragrance of blossoms. The Tartarian honeysuckle (*L. tatarica*) of Asia, is cultivated extensively. It is a large shrub and bears pink flowers and bright red berries. A good bush honeysuckle is Morrow's (*L. Morrowii*). It is a large hardy shrub. The fragrant honeysuckle (*L. fragrantissima*) is an early species and bears creamy white flowers. The climbing trumpet honeysuckle (*L. sempervirens*) is a favorite, with bright scarlet and yellow flowers. Hall's honeysuckle (*L. Halliana*) is a rampant grower and often escapes from cultivation and runs wild.

Hop (*Humulus lupulus*). A perennial vine of the nettle family which grows conelike fruiting catkins composed of leafy bracts surrounding the female flower cluster and known as "hops." The hops contain a resinous substance used in brewing. Staminate and pistillate flowers are produced on separate plants. Most of the hops of the United States are produced in California, Oregon and Washington. The Japanese hop is grown as a decorative garden plant. It does not produce hops.

Horehound (*Marrubium* spp.). A genus of perennial herbs of the mint family, native to the Mediterranean region but now found wild all over the world. An extract of the plant is used in candies and sirups for its medicinal value especially as a cough remedy. The name is derived from the "hoary" appearance of the down-covered leaves. Small white flowers occur in clusters on the leaf axils.

Horse Nettle (*Solanum carolinense*). An American weed, closely related to the potato. It spreads rapidly by underground stems. The plant bears thorns on the stem and leaves. The flowers are bluish and they are followed by orange berries.

Horse Radish (*Rorippa armoracia*). A perennial of the mustard family, grown for its pungent root which is used grated as a condiment. It is a native of Europe but has become naturalized in America. Propagation is easily accomplished by planting root cuttings.

Horsetail (*Equisetum* spp.). A genus of plants related to the ferns. They are flowerless and bear spores. There are two growths—a summer vegetative one and in the spring a fruiting growth which bears the spores. The common horsetail (*E. arvense*) is poisonous to horses but not to cattle or sheep. The plant is laden with silica and was used in earlier days for polishing and cleaning metal and wood, hence the name "scouring rush."

Horseweed (*Erigeron canadensis*). An annual of the composite family, which is often troublesome as a weed, especially in mint fields in Michigan. The plant ranges in height from a few inches to huge stalks higher than a man.

Huckleberry (*Gaylussacia* spp.). Although properly confined to species of *Gaylussacia*, the term huckleberry is often made to include the blueberry (*Vaccinium* spp.), especially in the Southern and Middle Western States. Huckleberries contain ten noticeable seeds. Blueberry seeds are numerous but so small as not to be important. Both berries belong to the heath family. The huckleberry bears reddish flowers and glossy, black berries. Its range is from Newfoundland to Georgia and west to Wisconsin and Kentucky.

Hyacinth (*Hyacinthus orientalis*). A fragrant house and garden flower of the lily family. Propagation is from bulbs. Two well-known groups are the Dutch and Roman types. The Dutch hyacinths are more stiff and formal; the Roman are smaller flowered and with several spikes of bloom from each bulb. Colors of flowers cover a wide range, including red, white, blue, mauve and yellow.

Hydrangea (*Hydrangea* spp.). A genus of ornamental flowering shrubs of the saxifrage family bearing great heads of bloom. The hardy hydrangea (*H. paniculata grandiflora*) is very common. Its flowers are white. The tender hydrangea (*H. opuloides*) is a dwarf and flowers early in greenhouses. Flowers range from white to pink and light blue.

Iceland Moss (*Cetraria islandica*). An edible lichen resembling moss in appearance. It is found in abundance in northern countries where it is used for food. It is dried and made into a bread. It is also used in making paper and cloth.

Indian Pipe (*Monotropa uniflora*). A colorless plant, either parasitic or saprophytic, found in rich, moist forests. The nature of the plant has led to its being called "corpse plant" and "ghost flower." The flower is borne on a stalk four to ten inches high. When the fruit is formed the hanging flower head straightens to an upright position.

Indigo (*Indigofera* spp.). A plant of the pea family, native to Asia and grown in tropical countries for the blue dye which is extracted from the cut plants by steeping in water. After the water treatment indigo crystals are secured by evaporation. The use of indigo as a dye has declined due to the increased use of aniline dyes. The distinctive color of indigo has led to many uses of the name, for example, as the name of one of the colors of the spectrum; also there may be noted the indigo bird and the indigo weed.

Ipecac (*Uragoga ipecacuanha*). A creeping plant of tropical South America. It is used medicinally for the drug which is extracted from the root of the plant. Combined with opium ipecac forms Dover's powder, an anodyne diaphoretic (a soothing agent causing perspiration).

Iris (*Iris* spp.). A garden plant with beautiful lily-like flowers of various colors. The name means "rainbow" and refers to the range of colors of the flowers. The iris is also known as the fleur-de-lis, or "flower of the lily." Some irises have bulbs and others have thick underground stems. Some flowers are bearded, while others are plain. Among the important irises are the common blue flag (*I. versicolor*), the Western blue flag (*I. missouriensis*), English iris (*I. xiphioides*), Japanese iris (*I. laevigata*), tall bearded iris (a group of hybrids) and the dwarf bearded iris (*I. pumila*).

Ironweed (*Vernonia* spp.). A wild flower of the composite family, common throughout the United States from the Dakotas and Texas eastward. With its reddish-purple flowers it is sometimes mistaken for an aster. The ironweed is a troublesome pasture weed and with its prodigious seed-producing ability rapidly takes possession of the land if not controlled.

Ivy. In America the name is commonly used for the woodbine (Virginia creeper) or the Boston or Japanese ivy, species of *Psedera*. The English ivy (*Hedera helix*) does not thrive in America except along the southern Atlantic slope. Poison ivy (which see) belongs to the sumac family. Ground ivy belongs to the mint family.

Jack-in-the-Pulpit (*Arisaema triphyllum*). A wild flower of the arum family, found in woodlands in eastern North America. The stem rises from a corm or turnip which was eaten by the Indians. Small greenish-yellow flowers are borne at the base of a club-like spadix or "jack." A hooded spathe surrounds the spadix and curves over at the top, making the sounding board over the "pulpit." The Indians also cooked the red berries and ate them.

Jasmine or **Jessamine** (*Jasminum* spp.). Erect or climbing shrubs of the olive family, grown as hardy plants in the Southern States and in greenhouses in the North. *J. nudiflorum* is an early bloomer with bright yellow flowers. *J. officinale* has fragrant white flowers. The common yellow jasmine, a favorite climbing evergreen of the South belongs to another genus and is scientifically recorded as *Gelsemium sempervirens*. As already mentioned, the cape jasmine is a gardenia.

Jewelweed or **Touch-me-not** (*Impatiens biflora*). A wild flower found in moist places throughout our country, except in the Southwest. The orange flowers marked with brown hang like jewels. The seedpods pop open at the touch and eject their contents over a radius of several feet.

Jimson Weed (*Datura stramonium*). A poisonous plant of the nightshade family found throughout North America. In Asia and Europe the plant has long been esteemed for medicinal uses, the seeds yielding an alkaloid. Large white trumpet-shaped flowers are followed by a prickly egg-shaped seed pod, which has led to the name of "thorn apple."

Joe-Pye Weed (*Eupatorium purpureum*). A wild flower which is found in moist meadows and woodlands throughout eastern North America. It belongs to the composite family and is a relative of the ironweed. The purple flowers are sought by insects for their nectar. Joe-Pye was a New England medicine man who claimed to cure typhus fever with a remedy made from this plant.

Jonquil. See Narcissus.

Judas Tree. See Redbud.

Jujube (*Zizyphus* spp.). Shrubs or trees of the buckthorn family, native to the area east of the Mediterranean Sea. The jujube is cultivated for its edible fruit which is about the shape and size, or larger, than that of the olive. The fruit is eaten raw or dried. The trees are ornamental. The jujube has been introduced to a limited extent in our Southern States.

Juniper (*Juniperus* spp.). A large genus of evergreen trees with berry-like cones, belonging to the pine family. The junipers include certain trees that are commonly called cedars, for example the red cedar (*J. virginiana*) of the eastern United States. This

tree is valuable for its wood which is used in making lead pencils and for posts and railroad ties. Juniper wood is used in making so-called "cedar chests." The dwarf or common juniper (*J. communis*) varies from a shrub to a tree of thirty feet. The Western juniper (*J. occidentalis*) is found growing at elevations of from 7,000 to 10,000 feet. It attains a trunk diameter of ten feet and specimens are known which are over 2,000 years old. The red juniper (*J. barbadensis*) is a handsome tree with a drooping leaf-spray resembling ferns and with silvery white berries.

Jute (*Corchorus capsularis*). An annual of the linden family. *C. capsularis* and *C. olitorius* are commonly called jute and together produce a vast amount of bast fiber, second in use only to cotton fiber. The commercial supply is grown in northeastern India where about 3,000,000 acres are given over to its cultivation. Jute is made into twine, cordage, burlap and bagging. Damaged and worn-out jute product is used for oakum and in paper making.

Kafir. A South African grain sorghum now grown extensively in the United States as "Kafir corn." The seeds are used like shelled corn, especially as poultry feed. The stalks make good forage and ensilage. See Sorghum.

Kale. A headless, curly-leaved variety of the cabbage species grown for winter greens and as food for stock. Another name for the plant is borecole, meaning "husbandman's cabbage."

Kalmia. See Laurel.

Kapok tree (*Ceiba casearia*). The kapok silk-cotton tree is a native of tropical America now grown principally in Java. The seed pods yield an elastic fluffy silky fiber which is buoyant in water. It is not good for spinning. The principal uses of the fiber are for stuffing life preservers and for filling mattresses and comfortables.

Kelp. See Algae.

Kohlrabi. (*Brassica caulorapa*). A vegetable grown for the edible enlarged swelling of the stem which appears just above the ground. This enlarged part of the stem bears a number of leaf stalks.

Kudzu (*Pueraria Thunbergiana*). A leguminous vine, imported from Japan and grown in the United States as a forage plant. Purple flower clusters are occasionally produced, though the plant rarely blooms.

Kumquat (*Fortunella* spp.). A small ornamental citrus tree, native to the Orient and now grown in Florida and California. The flowers are small, white and fragrant. The fruit is about the size of an olive but like an orange in color and structure. The entire fruit is eaten raw, or it may be preserved or candied.

Lady's Slipper (*Cypripedium* spp.). Wild flowers of the orchid family. Several species are natives of North America. The pouch-like lip of the corolla, resembling a shoe, has given the name "lady's slipper" or "moccasin flower" to this plant. The stemless lady's slipper or moccasin flower (*C. acaule*) is a well-known white or pink species which has been chosen as the state flower by Minnesota. The showy lady's slipper (*C. spectabile*) has hairy leaves and large white flowers marked with red. The large yellow lady's slipper or yellow moccasin flower (*C. pubescens*) can easily be naturalized in the home garden.

Larch (*Larix* spp.). Conifers of the pine family. The larches are not evergreen, and shed their leaves in the autumn. These trees prefer cool, moist regions and are found throughout the North Temperate Zone. Small cones are borne erect and leaves are in clusters on short spurs on the twigs. The trees are ornamental and the wood is good for telegraph poles, railroad ties and fuel. The tamarack, or American larch (*L. laricina*), is a useful tree for its wood. The Western larch (*L. occidentalis*) is perhaps the finest of the larches. It attains a height of 200 feet and a trunk diameter of six feet.

Larkspur (*Delphinium* spp.). Wild and garden flowers of the crowfoot family, noted for their handsome flowers. The spurred calyx has given the flower its common name. Wild larkspurs in our Western states have proved poisonous to livestock. As a garden plant there are annuals and perennials. Commonly, the name "larkspur" is reserved for the annuals and the perennials are called *Delphiniums*. The name *Delphinium* is derived from "dolphin" because the buds were said to resemble this animal.

Laurel. A name applied not only to shrubs and trees of the laurel family, but also to some of the heath family. The laurel of history or the sweet bay (*Laurus nobilis*) is a famous Old World species. The California laurel (*Umbellaria californica*) is a handsome tall tree with lustrous, evergreen leaves and is valuable as a cabinet wood. The red bay (*Persea Borbonia*) is a native tree of our Southern states and a worthy cousin of *L. nobilis* of Europe. The avocado, or alligator pear, (*P. gratissima*) is a wild laurel of Mexico and South America which has been developed into an important fruit tree. The fruit is a favorite as a salad. The sassafras is the only remnant of an old genus of the laurel family. The mountain laurel (*Kalmia latifolia*) of our Eastern states belongs to the heath family. This beautiful evergreen bears handsome flowers in great clusters of rosy pink. It is the state emblem of Connecticut. *K. angustifolia* is sheep laurel, or lambkill.

Lavender (*Lavandula* spp.). A genus of shrubs of the mint family. The common species (*L. vera*) is grown commercially in Europe for its oil which is used medicinally and as a perfume. The plant is grown to a limited extent in American gardens. The flower is small and pale blue; it will remain fragrant if dried.

Leek (*Allium porrum*). A biennial of the lily family, resembling the onion but milder to the taste. It has a smaller bulb than the onion and a thickened stem. In cookery, the leek is more popular in Europe than in America. It has for a long time been the floral emblem of Wales.

Lemon (*Citrus limonia*). An evergreen tree and its light-yellow acid fruit, related to the orange. The lemon is a native of Asia and was cultivated in India thousands of years ago. Lemons are grown today in the subtropical portions of Asia and Europe and in America, especially in California. Besides the fruit, which is widely used for its juice, valuable by-products include citric acid and lemon oil.

Lentil (*Lens esculenta*). A member of the pea family, grown in Europe, Asia and Egypt for its lens-shaped seeds, which are used for food. It is said that the red pottage mentioned in the Bible story of Esau was a dish of red lentil seeds. The lentil has never become popular in America, though some varieties have been cultivated in the Southwest. The lens derives its name from the lentil whose seed is flat and convex on both sides like the typical double lens.

Lettuce (*Lactuca sativa*). The most important salad plant and extensively used also for garnishing. It is a member of the composite family and is a native of the regions around the Mediterranean Sea, where it has been grown for hundreds of years. Lettuce is grown all over the world in warm and temperate climates in gardens. It constitutes the most important greenhouse vegetable in autumn and winter. Although not high in nutritive qualities, lettuce is valuable for its vitamin content. Many varieties are cultivated. Three types are known—leaf, head and Cos, or Romaine.

Lichens. Lichens consist of two plants, one a fungus and the other an alga, living together in a relationship known as "symbiosis." The work of the alga is to provide food, while the fungus absorbs water and offers protection to the alga. Lichens occur on boulders, on bark, and in the polar regions such forms as Iceland moss (which see) and reindeer moss form important articles of food to man or beast. Litmus dye is obtained from lichens.

Licorice (*Glycyrrhiza glabra*). A European plant of the pea family, with blue flowers, cultivated for its roots which yield the licorice used in candies, for flavoring medicines, in making certain soft drinks and in flavoring plug tobacco. Licorice culture has never flourished in this country and our supply is imported. The wild licorice (*G. lepidota*) found in the United States is a related species. It is sought by children who chew its roots. It lacks, however, the characteristic sweetness of the European species.

Lignum-vitae (*Guaiacum* spp.). Any of a genus of tropical trees of the bean caper family, important for their heavy, hard, oily wood which sinks in water. Gum guaiacum, used in medicine, is extracted from the wood. A species (*G. sanctum*) is found in Florida.

Lilac (*Syringa* spp.). An old-fashioned shrub of the olive family, found widely in all climates. The plant is a native of Asia and Europe, but is found growing half wild throughout the northeastern United States. The common lilac (*S. vulgaris*) bears purple flowers. The white lilac (*S. vulgaris alba*) has very fragrant flowers and is a favorite for planting. The Japanese lilac grows to the size of a small tree, but the flowers are not fragrant.

Lily (*Lilium* spp.). A genus of bulbous plants with scattered leaves and showy flowers. A number of species are native to the United States. The white Madonna lily (*L. candidum*) has fragrant, pure white, trumpet-shaped flowers. The Eastern lily (*L. longiflorum*) is less successful outdoors, but is used almost entirely for forcing in pots. Other species include the gold-banded (*L. auratum*), the regal (*L. regale*), the scarlet Turk's-cap (*L. chalcedonicum*) and the well-known tiger lily (*L. tigrinum*).

Lily-of-the-Valley (*Convallaria majalis*). A low perennial bearing small, white, globular flowers on long graceful flower stalks. It is commonly grown on the north side of the house, though it will flourish in the sunshine. A poisonous alkaloid, convallarin, is extracted from the juice of the plant.

Lime (*Citrus aurantifolia*). An evergreen tree related to the lemon, grown for its small, greenish-yellow acid fruit which is used for its juice in drinks and as a flavoring. Limes grow wild in the tropics and cultivated varieties are grown for commerce. Our supply comes principally from the West Indies and Mexico, though some are produced in the Florida Keys. Citric acid is obtained as a by-product.

Linden. See Basswood.

Litchi (*Litchi chinensis*). A long-lived tree of China bearing a fruit which is sold in this country as the "litchi nut." The dried fruit has a rough, brittle outer coating. The inside fruit is shrunken and resembles a raisin in appearance and has a pleasing subacid taste.

Live-forever (*Sedum purpureum*). A member of the stonecrop family, naturalized in the Alps region and brought to America later. Originally a garden plant, it has become a troublesome field plant. The name is derived from the fact that shoots or cuttings preserve their vitality a long time and will easily take root and grow. Small purple flowers are borne on the ends of shoots. There are many other Old World species.

Liverworts. Spore-bearing plants resembling mosses. They grow in wet places.

Loco Weed (*Oxytropis Lamberti* and *Astralagus* spp.). Various plants, all members of the pulse family, which produce a nervous affection of livestock, especially horses, often causing death. The white loco, or rattleweed (*O. Lamberti*), is the most widely distributed. The purple loco, or woolly loco (*A. mollissimus*) is especially prevalent in Texas. The blue loco (*A. diphysus*) is found throughout the Southwest. Animals, after eating loco weed, lose weight, stop eating and drinking and die of starvation.

Locust (*Robinia* spp.). Forest trees of the pea family, with showy pea-like flowers and leaves that droop and close at nightfall or upon the approach of rain. The fruits are thin pods. Thorns grow on the trunks and twigs. The common locust consists of two forms not different botanically (*R. pseudacacia*); one is the yellow and the other the black, so called from their yellowish and brown woods. The clammy locust (*R. viscosa*) with pink flowers is a favorite ornamental.

The honey locust (*Gleditschia triacanthos*) is not properly a locust, but it is a member of the pea family. Its pods, in addition to the seeds, contain a sweet, gummy pulp which small boys like to eat. The tree is also very thorny.

Loganberry. A bramble fruit, now considered a variety of climbing blackberry. It bears a long purplish berry, acid until fully ripe. The plant grows in the Pacific Northwest. It is used fresh, dried and canned.

Loquat (*Photinia japonica*). An evergreen tree of the rose family, a native of China and Japan and now grown in our country in the Gulf states and in California. The tree grows to a height of about twelve feet. Fragrant white flowers are produced in the autumn and in the spring pearlike or round fruits yellowish in color. The large seeds are sometimes used in cookery. The fruit is used for pies, jams and jellies, and may be eaten raw.

Lotus. A name given by the ancients to various plants, especially jujube trees, whose fruits were eaten as food. The name was also given to several nymphaeaceous plants, including the blue water lily and the Nile water lily. In America, the yellow water lily (*Nelumbo lutea*) is called the lotus.

Lupine (*Lupinus* spp.). Plants of the pea family named after *lupus*, the wolf, because they were said to prey on the soil. Although found in the eastern sections, they occur principally in the western United States. The ancients grew lupines and ate their seeds. In America, the lupines produce poisonous seeds, resulting often in the death of livestock. The flowers are usually blue or purple, but sometimes white or yellow. Lupines are also grown as garden flowers. The blue bonnet, state flower of Texas, is a lupine.

Madder (*Rubia tinctorum*). A European herb with small yellowish flowers. Its root is used in making a red dye.

Madroña (*Arbutus menziesii*). A small evergreen tree or shrub of the heath family, native to the Pacific coast region of North America. It bears edible orange-red fruits called "madrona apples." The wood is used to make a charcoal used in the manufacture of gunpowder.

Magnolia (*Magnolia* spp.). A genus of trees and shrubs with aromatic bark and large white, pink or purple flowers. Magnolias have the largest flowers of any cultivated trees. The blossoms often measure a foot across. The petals are thick and waxy. The foliage helps also to make the magnolias preferred ornamentals. The large-leaved umbrella tree (*M. macrophylla*) is one of the best known of the umbrella trees. The flowers resemble those of the water lily. The sweet bay (*M. glauca*) of the southeastern United States is less ornamental, but its wood is valuable. *M. grandifolia* is the state flower of Louisiana and Mississippi.

Mahogany (*Swietenia mahagoni*). A tree of tropical and subtropical countries, found to a limited extent in Florida Everglades. The principal producing countries are Mexico, Central America, West Indies and Africa. The timber is valuable for furniture. It is reddish brown, of uniform grain and color and takes a high polish. It is used extensively for cabinet work and for veneers.

Mandrake or **May Apple** (*Podophyllum peltatum*). A herb of the barberry family, found in rich, moist woodland in the eastern United States and in Japan. All parts are poisonous, except the yellowish, lemon-shaped fruit, which is often eaten by children. This practice should not be encouraged as illness may result.

Mangel-wurzel (*Beta vulgaris macrorhiza*). A plant of the beet family grown for its long root which is used as a succulent food for livestock. It grows best in cool climates and is produced in the northern United States and Canada.

Mango (*Mangifera indica*). An evergreen tree, native of southern Asia where it has been cultivated since ancient times for its fruit. The tree belongs to the sumac family and is related to the pistachio nut. The flowers are yellow or reddish and the fruit is yellowish and variable in shape and weighs, in the better varieties, up to four pounds. The fruit is eaten raw and, when partly green, is used for pickles and sauces. The seeds are roasted and eaten by the people of the tropics.

Mangrove (*Rhizophora* spp.). A tropical and sub-

tropical tree with characteristic aerial prop roots. It grows in low, muddy flats. The seeds sprout before leaving the parent plant and thus are able to take up their peculiar separate existence. The trees attain a height of seventy-five feet and often reach a diameter of three feet or more. The red mangrove is best known. Other species are the white and the black.

Manila Hemp. See Abaca.

Manzanita (*Arctostaphylos* spp.). Shrubs or small trees of the heath family, with white or pink flowers and fruits somewhat resembling little apples, hence the Spanish name *manzanita*, or "little apple." A number of species are found in the mountains of California.

Maple (*Acer* spp.). A genus of trees widely distributed over the Northern Hemisphere with one species growing in Java. The maple yields a pale, fairly hard wood and a clear sap which is often made into maple sugar. The maples bear opposite, simple leaves, palmately veined and lobed. The fruits are two samaras, compressed and drawn out into large thin wings, each containing a single seed. The original home of the maple is in the Far East.

The Norway maple (*A. platanoides*) and the sugar maple (*A. saccharum*) resemble each other, and the black maple (*A. nigrum*) is much like the sugar maple. The two latter are common species of eastern America. The red (*A. rubrum*) and silver (*A. saccharinum*) maples are known as soft maples; they grow in low moist lands. The box elder, or ash-leaved maple (*A. negundo*), is marked by its compound leaves; it grows from Vermont to Manitoba south.

Marigold (*Tagetes* spp.). Old-fashioned garden flowers with yellow blossoms, varying in some to brownish. The African marigold (*T. erecta*) is a tall type. The French marigold (*T. patula*) is a dwarf with flowers of a velvety cast. *T. signata pumila* is another dwarf with an abundance of small golden flowers.

Marjoram, Sweet (*Origanum majorana*). A European herb of the mint family grown in our country. It is cultivated for its flowers and stems, which have a pleasant flavor when used as a seasoning in cookery. The oil is used in soaps and perfumes.

Marsh Marigold (*Caltha palustris*). A lowland plant of the crowfoot or buttercup family. It is not a marigold and bears no resemblance to the true marigolds. It is a native wild flower of the eastern United States. The flowers are bright, shining yellow. The edible leaves are often used as greens.

Mayweed (*Anthemis cotula*). A weed of the composite family occurring throughout North America along roadsides and in dry or sandy areas. The flowers are small and resemble daisies. Another species, the garden camomile (*A. nobilis*), is made into an aromatic tea, said to be a blood purifier.

Medlar (*Mespilus germanica*). A small European tree cultivated for its fruit which is related to the apple and pear. It has not been cultivated to any degree in the United States. The fruit is mainly used in making preserves, as it is acid, hard and somewhat gritty.

Mesquite (*Prosopis* spp.). Trees and shrubs of the pea family, native to the Southwest and especially abundant in Texas. The hard, close-grained, reddish wood is prized for fence posts, railroad ties and fuel. The beans are eaten by man and beast, and the green shoots serve as excellent cattle food. The common mesquite (*P. juliflora*) has long pods and the screw-bean or screw-pod has spirally twisted pods. The very long woody roots are often pulled out by teams or machines and used for fuel.

Mignonette (*Roseda odorata*). Mignonette, or "little darling" is a garden flower grown for its fragrance. Normally a small plant, it has been improved and the size of the plant and the dense spikes of flowers much enlarged, but at the expense of loss of fragrance. The Romans used the flower to treat bruises.

Milkweed. Any of various plants which yield a milky fluid when injured. More than 1,900 species of the milkweed family (*Asclepiadaceae*) have been determined. The common milkweed, or silkweed (*Asclepias syriaca*), is common in the United States and Canada. The flowers are greenish purple pink or brownish pink. The pods contain a downy silk. The orange milkweed, or butterfly weed (*Asclepias tuberosa*), is distinguished by its brilliant clusters of bright reddish orange flowers. As the name suggests, this flower is a prime favorite of the butterflies. The group of whorled milkweeds differ from the common milkweeds in having narrow, whorled leaves. Many of the milkweeds are poisonous and, wherever abundant, they are among the troublesome weeds. See Butterfly Weed.

Millet. Any of various annual grasses used in our country principally as forage plants or for poultry feed. In the Old World millets are grown extensively for their seed which is used for human food. The leading groups include foxtail millet, pearl millet, broomcorn millet, barnyard millet and ragi millet. In the United States, foxtail millet (*Chaetochloa italica*), an immigrant from Asia originally, is the most common, although production has declined in recent years. Broomcorn millet has a brushy head and is cultivated mostly for the grain, which is fed to poultry. Ragi millet is an important crop in India, where it forms an important item of food among the lower classes.

Mints (*Labiatae* or *Menthaceae*). A large family of aromatic herbs, the members of which easily mix, making classification difficult. Included are such familiar species as peppermint (*Mentha piperita*) and spearmint (*Mentha spicata*), both of which yield important commercial oils. True pennyroyal is a European plant (*Mentha pulgeium*) of similar fragrance to the American pennyroyal (*Hedeoma pulegioides*). Both are used in salads and for seasoning and tea. Other mints include lavender, sage, marjoram, thyme, basil, rosemary and horehound.

Mistletoe (*Phoradendron* spp. and *Razoumofskya* spp.). Parasitic plants which grow on trees. The mistletoe sends suckers into the tree for water and mineral food, and makes its own sugars and starch with its chlorophyll equipment. The plant has fleshy, evergreen leaves and white berries. The southern, or leafy, mistletoes belong to the genus *Phoradendron* and occur on deciduous trees and occasionally on evergreens. The dwarf mistletoes are of the *Razoumofskya* genus and are found on various evergreen trees. Mistletoe is principally used as a decoration for Christmas festivities.

Moneywort (*Lysimachia nummularia*). A handsome trailing, perennial wild flower which is often a troublesome weed in lawns and pastures. It belongs to the primrose family. The flowers are golden-yellow.

Moonflower (*Calonyction pandurata*). A climbing plant of the convolvulus family and related to the morning glory. It is a night bloomer; the flowers are flatter than those of the morning glory, white with purple throats. It is commonly grown as a shading vine for porches. In fields it often becomes a troublesome weed.

Morning Glory. Various plants of the convolvulus family, of which the chief members belong to the genus *Ipomoea*. The common morning glory (*I. purpurea*) is grown as a garden flower. Both single and double varieties are cultivated. A Japanese variety has unusually large leaves and blossoms. A worth-while garden flower is the blue-flowered *Coerulea superba*.

Mosses (*Musci*). A class of the Bryophytes, having small leafy or tufted stems which bear sex organs, just below the ferns in the plant kingdom. Mosses occur all over the world, but are especially numerous in cold regions. There are three principal divisions of the mosses. The *Sphagnum* forms, including peat mosses, occur in wet areas. The *Byrales*, or true mosses, and the *Andreaea*, or rock mosses are the other divisions.

Mountain Ash (*Pyrus* spp.). A group of small trees of the rose family and closely related to the apple. They are called ashes because of the resemblance of their leaves to those of the true ashes. The foliage is almost fern-like in delicacy. The fruits are brilliant orange-scarlet berries, which are borne in great clusters. The American mountain ash (*P. americana*) is not grown as extensively in our country as the European species, *P. aucuparia*. The mountain ashes are used as ornamentals, especially for borders.

Mulberry (*Morus*). A genus of trees of the large mulberry family native to the temperate zone in America and the Old World. The white mulberry (*M. alba*), a native of the Orient, is the original silkworm mulberry. It grows partly wild in the eastern United States. The red mulberry (*M. rubra*) is native to America and is valuable for its wood. The black mulberry (*M. nigra*) produces the best fruit for eating and is cultivated for that purpose.

Mullein (*Verbascum thapsus*). A wild flower and a weed of the figwort family, of dry fields and waste land, native to eastern America and Europe. It has coarse woolly leaves and terminal spikes of yellow, purple or white flowers.

Mushroom. The term, mushroom, was formerly applied to the edible fungi (which see), while the poisonous forms were known as toadstools. The tendency today is to apply the word, mushroom, to all fungi, distinguishing between the edible and the poisonous. The edible mushrooms cultivated for the market are largely *Agaricus campestris*.

Muskmelon (*Cucumis melo*). An annual vine belonging to the gourd family. It grows in warm climates or weather. It is a native of Asia and has become important in our country, where it is esteemed for its delicious, fleshy fruit. The term "cantaloupe" is properly applied to the hard rind European varieties, but is used in reference to the American varieties which are small, round and heavily netted. Recently, the winter muskmelon, or casaba, has gained popularity.

Mustard. Any of a large number of annuals of different genera of the mustard family, marked by their production of large quantities of small, pungent, oily seeds. Mustard is cultivated in California for the seeds which are made into a table condiment. In the south of our country mustard greens are used. The principal production of mustard is in Europe and our country imports millions of pounds annually. The leading species under cultivation belong to the genus *Brassica* and include black, white, brown and Japanese mustard. As weeds in America, the above mentioned species and others grow wild. Other mustards which are found wild include the tumbling mustard (*Sisymbrium altissimum*), hedge mustard (*S. officinale*) and garlic mustard (*Alliaria officinalis*).

Narcissus (*Narcissus* spp.). A genus of bulbous plants of the Old World of the amaryllis family, deriving its name from an ancient Greek myth concerning the youth Narcissus. In the center of the yellow or white flower is a conspicuous trumpet. Species with long trumpets are called daffodils. Those with medium trumpets are known as narcissi, though sometimes referred to as jonquils. The short-trumpet species include the true jonquils.

Nasturtium (*Tropaeolum* spp.). A popular garden plant cultivated for its showy flowers of yellow, scarlet and maroon. The leaves are large and umbrella shaped. The tall species (*T. majus*) reaches a height of twenty feet or more. The dwarf (*T. minus*) is also known as the Tom Thumb.

Nettle (*Urtica* spp.). A genus of coarse herbs with small greenish flowers and equipped with stinging hairs on the leaves. The stinging nettle (*U. gracilis*) is found in the northern two-thirds of the United States east of Colorado and in Canada. It is a roadside and barnyard weed. Another nettle (*U. dioica*) was cultivated in Europe during the World War for its fiber which was made into a coarse cloth. A yellow dye is obtained from the roots, and certain nettles when young and tender are boiled and eaten as greens.

Nightshade (*Solanum* spp.). Annual and perennial plants related to the potato. Included among the nightshades are the black nightshade (*S. nigrum*) and the bittersweet nightshade (*S. dulcamara*). The poisonous qualities of the black or red fruits of the nightshade have been debated. They are probably mildly poisonous and should be avoided. Instances of eating the cooked berries in pies have been reported. The deadly nightshade has already been described under Belladonna (which see).

Nutmeg (*Myristica fragrans*). An evergreen tree of the East Indies, now also grown in the West Indies. The fruit splits to release the nut and around the nut is a scarlet membrane from which mace is made. The nutmeg was formerly eaten as a food, pickled or in a sirup. Today it is ground and used as a spice.

Oak (*Quercus* spp.). A large genus of hardwood trees, often referred to as the cup-bearers. The fruit, the acorn, is borne in a cup and by this the oak is known everywhere. Some oaks fruit annually, others biennially. The leaves are simple, five-ranked and usually oval. Leaves hang on until spring, and in the live oak for three or four years. The oaks make good shade trees and are valuable for their lumber.

One group is the white oaks. These include the white oak (*Q. alba*), burr oak (*Q. macrocarpa*), post oak (*Q. stellata*), chestnut oak (*Q. prinus*) and the live oak (*Q. Virginiana*). The white oak is perhaps the most valuable of all. Its wood is in demand, its bark is used for tannin and the tree is important for shade.

The other group is known as the black and red oaks. Included here are the black oak (*Q. velutina*), scarlet oak (*Q. coccinea*), pin oak (*Q. palustris*) and willow oak (*Q. Phellos*).

Oat (*Avena sativa*). An annual grass derived from wild species, chiefly *A. fatua* and *A. sterilis*. Cultivated oats have been grown for thousands of years and probably originated in southeastern Europe, where they were long used as food for animals. Only with the introduction of modern milling methods have oats become an important article of human food. Today oats rank as the third most important cereal crop in North America. The grain is eaten in the form of rolled oats or oatmeal. Wild oats (*A. fatua*) are sometimes sowed as a forage crop, but this is usually a bad practice; wheat and other fields may thus be infested for years with an undesirable plant that is hard to eradicate.

Okra (*Hibiscus esculentus*). Okra, or gumbo, is an annual of the mallow family, cultivated especially in the Southern States for its edible seed pods. The plant is a native of tropical Africa but is now grown in America as far north as New England. Okra is used in soups, or cooked as a vegetable, especially with tomatoes.

Olive (*Olea europea*). An evergreen tree of the olive family, probably a native of the Near East, though cultivated from time immemorial. The Franciscan Fathers introduced the plant into southern California over 150 years ago and there and in Arizona the olive is an important crop. The fruits are gathered and pickled, both ripe and green, for food. The oil is also an important article of commerce. The olive branch has long been regarded as a symbol of peace.

Onion (*Allium cepa*). A biennial member of the lily family with hollow leaves, grown for its bulbous edible root, which is used as a vegetable. The onion is a native of southwestern Asia, but has been grown in cultivation for thousands of years. It is an important crop throughout the United States, where also many imported varieties, including the Bermudas and the Spanish are grown. Wild onions are often troublesome pasture weeds.

Orange (*Citrus sinensis* and *C. aurantium*). The typical orange of commerce is the *C. sinensis*, the sweet orange. The sour orange, *C. aurantium*, is practically unfit to eat, though it is used in by-products and as orange stock. The sweet orange is widely grown in warm regions all over the world. In the United States, California and Florida are the principal producing states. Alabama, Louisiana, Arizona, Mississippi, Texas and Georgia also produce considerable amounts. The Washington Naval and the Valencia are the most important American varieties. Oranges are eaten fresh and the juice is a refreshing drink. The peel is dried and candied. Orange paste and orange oil are other products.

A group of oranges known as "kid-glove oranges" (*C. nobilis*) have skin which separates easily from the pulp. This group includes the Mandarins, the

Satsumas and the tangerines. Tangerines are grown extensively in the Gulf States.

Orchard Grass (*Dactylis glomerata*). A tenacious perennial forage grass. Its distinctive crowded flower clusters easily mark this plant. It is a native of England where it is known as "cocksfoot." It is produced in practically all of the sections of our country.

Orchid (*Orchidaceae*). A family of over 5,000 species of peculiar plants found all over the world except in very cold or very dry regions. They are most abundant in the tropics, where they commonly grow on trees. They are not parasites, but send out long roots into the air and thus obtain food. At the leaf base water is often stored and used in times of drought. The flowers assume fantastic shapes and are often delicately colored. Orchids are prized as greenhouse flowers. Since they are raised slowly from seed, they are expensive. Native American species include the lady's slipper, grass pink and various species of *Orchis*. Our native orchids all grow in the soil and not in trees.

Osage Orange (*Toxylon pomiferum*). A thorny tree of the mulberry family, native to the region between Missouri and Texas. The juice is milky. Pollen is produced on the flowers of one tree, while fruits are borne on another tree. The fruits are round and from four to five inches in diameter. They are hard, yellow and unfit to eat. The wood of the tree is strong and heavy and useful for woodenware, ties, posts and tool handles. The Osage orange is often grown as a hedge.

Palm (*Palmaceae*). The palms are tropical plants related to the lilies and to the grasses. They include about 1,200 species. The leaves are fan-shaped or feather-like. The flowers are in great clusters and the fruits are clustered berries. Palms supply many valuable products, including sago, dates and coconuts. Much of the "nut margarine" comes from palms. Sugar, starch, wax and resin come from palms. The outer wood is often hard and is useful. The leaves are used for cloth and for thatching roofs.

The royal palm is a popular shade tree along the streets in tropical and semi-tropical cities. It may reach a height of 100 feet. The Canary Island palm is a favorite avenue tree in California. It is of the feather-leaved type and wears a crown of plumes and bears huge clusters of bright yellow berries. The date palm demands very warm temperatures far above the hundred degree mark. It has been successfully introduced into such American locations as the Coachella Valley, in California. The coco palm is a tall pinnate-leaved tree which bears the familiar coconut. The palmetto is a palm-like plant found from North Carolina to Florida. Since the new end buds are gathered and cooked like cabbage, this plant is often called the "cabbage palmetto." The raffia palm of Madagascar yields the useful pliable raffia fiber of commerce. The rattan palm is found in the Far East. Among the small palms grown indoors, the Kentia is one of the most popular and easily grown.

Pansy (*Viola tricolor*). A cultivated perennial flower, related to the violet. It is known under many names, including "Johnny Jump-up," "heartsease" and "love-in-idleness." Its name is from the French *pensee*, meaning "thought." Pansies have wonderful velvety textures and exhibit a wide range of colors, including purple, yellow and blue with countless variations.

Papaw (*Asimina triloba*). The papaw, or pawpaw, bears the family name, custard-apple, from its unique fruit which looks like a banana and is soft and yellow like custard. It is native to the Southern States and is found as far north as Michigan and New York. Negroes especially prize the fruit which is sold in Southern markets.

Another fruit, called the "papaw," should properly be known as the papaya. It is *Carica papaya*, a herbaceous plant with large melon-like fruits weighing from ten to twenty pounds, yellow to orange in color. It is native to Mexico and Central America. The papaya yields an enzyme, papain similar to pepsin.

Parsley (*Petroselinum hortense*). A biennial vegetable of the parsley family used for seasoning and as a garnish. It is a native of the Old World and has long been a garden vegetable in all civilized countries. The oil of parsley is made from the seed and is used medicinally.

Parsnip (*Pastinaca sativa*). This biennial vegetable of the parsley family, cultivated since the Middle Ages in Europe for its edible root, was reported by Pliny to have been brought to Rome annually from beyond the Rhine to please the exacting palate of the emperor. Parsnips are grown for use as a winter vegetable, both for man and as food for cattle. The wild parsnip, from which the cultivated form has been developed, is often a troublesome weed. It is not, however, poisonous as has been claimed. It harbors a fungus that is injurious to celery and should not be allowed near celery plants.

Passion Flower (*Passiflora* spp.). A large genus of climbing vines, native to tropical regions but represented by several species in our country. The flowers in various species are pink, red or white. The name was given by early Spanish missionaries in America and refers to the crucifixion of Christ. The parts of the flower are said to resemble the nails of the cross, the marks of the wounds, the crown of thorns, and the five sepals and five petals symbolize the ten apostles, omitting Peter and Judas. *P. caerulea* is a good species for cultivation and produces large and beautiful flowers.

Pea (*Pisum* spp.). A hardy annual of the legume family including the garden pea (*P. sativum*) and the field pea (*P. arvense*). The pea was cultivated in very early times in western Asia and later in southern Europe. The plant bears white or pink flowers followed by pods containing rounded seeds.

The garden pea is grown in home gardens and commercially as a canning crop. There are two chief varieties, the wrinkled and the smooth seeded. The field pea is used in the Old World and in Canada for food, but it has not been used extensively for this purpose in the United States. In our country the field pea is chiefly raised as a forage crop and for green manure to enrich the soil.

Peach (*Prunus persica*). A tree and its fruit, a member of the rose family and a near relative of the plum. The varieties commonly grown in our country are all derived from *P. persica*. The peach is said to have been cultivated in China 2000 B.C., and spread from there to India, Persia and other places. The early Spanish explorers introduced it to America. Today it is our second largest fruit crop, ranking next after the apple. The peach is closely related to the almond. The smooth-skinned varieties are known as "nectarines." Peaches are classified as freestones and clingstones, though they cannot be thus strictly classified. Double-flowered varieties are grown as ornamentals.

Peanut (*Arachis hypogaea*). An annual of the pea family but differing from peas and beans in that the fruit is produced beneath the ground surface. The peanut is a native of South America where it has been grown since prehistoric times. It was introduced into Africa about 1500. During the past fifty years it has become of large importance in the United States where it is cultivated commercially as far north as Virginia. The peanut is known also as groundnut, earthnut, ground pea and goober. There are bunch and runner varieties of the peanut. The flowers are yellow and are followed by pods containing seeds. The pods bend downward and enter and ripen beneath the surface of the ground. Peanuts are eaten as food. Much of the crop is made into peanut butter, oil and peanut flour. The hay is used as food for stock.

Pear (*Pyrus communis*). A tree and its fruit, a member of the rose family and related to the apple. The fruit differs from that of the apple in general shape and in having characteristic grit cells, also in being sweeter and juicier. The pear originated in eastern Europe and western Asia and is mentioned in the writings of Homer and Pliny. It is usually the fourth largest fruit crop in the United States. The common American species is *P. communis*. The Oriental pear (*P. serotina*) is cultivated in China and Japan and has been introduced to some extent in our country. Dwarf pears are grown by grafting *P. communis* on quince stock.

Pecan. See Hickory.

Pelargonium. See Geranium.

Peony (*Paeonia* spp.). A perennial garden flower of the buttercup family. It is an excellent flower for cutting and thrives year after year in the same place. The Chinese peony (*P. albiflora*) is a native of Siberia. It produces large white to rose and magenta flowers, single or double. The common peony (*P. officinalis*) comes from south Europe and with its large red, pink or white flowers is perhaps most widely grown in our country. The tree peony (*P. moutan*) of the Far East is known as the moutan in the Orient. The stems grow from three to six feet in length and the flowers of rose, magenta and white often measure a foot across and are of a gorgeous satiny texture. The wild peony (*P. brownii*) is a native of our western mountains. It has reddish brown flowers.

Pepper (*Piper nigrum*). A vine of the pepper family cultivated for its berries. When dried the red berries become the peppercorns or ground pepper of commerce. The ripened berries peeled are known as white pepper. Pepper has been grown since ancient times in the East and the chief supply still comes from the Orient, Singapore being the leading pepper port. The pepper vines require support and are customarily planted around trees. Vines grow to a height of twenty or thirty feet but are easier to harvest when kept cut back to about eight feet. Vines produce for from seven or eight years to as much as thirty years. The berry is first green, then red, and finally yellow.

Pepper, Red (*Capsicum annuum*). Red pepper is an annual of the nightshade family, grown much like the tomato. The plant is grown for its pods, which are eaten green or used when ripe and red. Sweet peppers, or mangoes, are mild and are eaten stuffed and in salads. The pimento, or Spanish sweet pepper, is used in salads and to stuff olives. Small red peppers are used for pickling and flavoring and in catsups, chili con carne, chowchow and so forth. Mild red peppers yield the paprika of commerce. In making paprika the peppers are ground either with or without the seeds which make it stronger.

Peppergrass (*Lepidium* spp.). An annual or winter-annual of the mustard family. This branching bush-like plant is often a troublesome weed in pastures and meadows. The plant is from one to two feet high and bears small white flowers.

Peppermint (*Mentha piperita*). An important pungent mint, grown for its leaves from which is distilled an essential oil much used in flavoring candy and in medicine. The oil is used also in making soaps and perfumes. The peppermint grows wild in damp places, but is now extensively cultivated. The flowers are small and reddish-blue in color. The propagation is by rootstocks. Peppermint was introduced to America from Europe. Michigan, Indiana and Oregon produce large amounts commercially.

Pepper Tree (*Schinus molle*). An evergreen tree of the sumac family. It is a native of South America where the fruits are sometimes used for pepper. It has been introduced into California as an ornamental and shade tree. Since it acts as a host for certain injurious scale insects, its use has been discouraged.

Persimmon (*Diospyros* spp.). Trees and shrubs of the ebony family known for their fruit and for their hard elastic wood. The common persimmon (*D. virginiana*) occurs in many parts of the eastern United States, but thrives best in the South. The fruit is about the size of a plum and until after frosts is very puckery to the taste. Well into winter it becomes sweet and good to eat.

The Japanese species (*D. kaki*) has a much larger fruit. When thoroughly ripe it is delicious. Some varieties are seedless. On the fruit stands the persimmon is often mistaken at first sight for a tomato.

Pe-Tsai or **Chinese Cabbage.** A hardy member of the cabbage family, introduced to the United States from China. Its tightly wrapped leaves are self-blanching and may be eaten raw as a salad or cooked.

Petunia (*Petunia hybrida*). A garden annual of the potato family grown for its gaudy, frilled flowers which exhibit a wide range of colors. The plant is native to South America but has been largely naturalized in the eastern United States.

Phlox (*Phlox* spp.). A genus of annual and perennial flowers found wild and grown in gardens. The wild sweet William (*P. divaricata*) is found along the edges of woods and beside streams. It thrives in the garden. The perennial *P. paniculata* has won a well-deserved recognition. *P. Drummondii* or Drummond's phlox is an annual, native to Texas. The blooms range from white to various shades of red and purple.

Pine (*Pinus* spp.). A large genus of cone-bearing evergreen trees having typical needles arranged in bundles and enclosed at their base in a papery sheath. Soft pines have a soft wood, and shed their papery sheath before the leaves begin to fall. Hard pines have a heavy, dark-colored, resinous wood, and retain the leaf sheath until the leaves are shed.

The most important is the white pine (*P. strobus*) of the northeastern United States; the state flower of Maine is the cone and tassel. White pine is also abundant in the Lake states. The yellow pine (*P. palustris*), also known as the longleaf pine, is important as a lumber tree and in the production of pitch, turpentine, resin and oil. The western yellow pine (*P. ponderosa*) forms the most extensive pine forests in America. Other valuable pines of the West are the sugar pine (*P. Lambertiana*), the giant pine of the Oregon and California mountains, and the western white pine or mountain pine (*P. monticola*) of the Pacific Northwest. The scrub pine (*P. contorta*) is a lowly parent of one of the gigantic western lumber pines. A variety, *P. contorta latifolia*, is the lodge-pole pine, so called because it grows in a dense formation, straight and slender like wheat on the prairie. No wonder the Indians appropriated it for their lodges. Some pines of the Southwest are valued for their edible seeds. These are known as *Piñons*. They are much sought by the Indians, and are sold in markets in the West.

Pineapple (*Ananas comosus*). A tropical plant of the bromelia family, grown extensively for its fruit which emerges on a stalk rising from a cluster of spiny leaves. The fruit weighs from three to twenty pounds and resembles a great pine cone, from which it takes its name. Large acreages in the Hawaiian Islands and in Porto Rico are devoted to pineapples. The delectable fruit is either shipped to be eaten raw, or it is canned.

Pistachio (*Pistacia vera*). An Old World tree, a native of Asia Minor, known and grown since ancient times. It yields a small nut highly prized for its delicate flavor. It is used in flavoring ice cream and confections. Although grown to a limited extent in the Southwest, most of the American supply is imported from Sicily.

Pitcher Plant. Several genera of insect-catching plants. The best known pitcher plant is *Sarracenia purpurea*, found in northern bogs. These strange plants have specially developed pitcher-like leaves which are lined with downward-pointing hairs. Insects are beguiled and after crawling into the pitcher cannot retrace their way. At the bottom is a fluid which drowns the insect and decomposes its body which is probably used in the nutrition of the plant.

Plane Tree. See Sycamore.

Plantain (*Plantago* spp.). A genus of weedy plants including the narrow-leaf plantain or buckhorn (*P. lanceolata*) and the broad-leaf plantain (*P. major*). The narrow-leaf species is the more troublesome, since it invades meadows and pastures and kills off valuable grasses. The common broad-leaf plantain is a familiar lawn weed which grows close to the ground, choking out grass.

A totally different plant called "plantain" is *Musa paradisiaca*, a tropical tree-like plant said to be one variety of the common banana. The fruit is coarser than the ordinary banana and is always cooked before eating.

Plum (*Prunus* spp.). Trees and shrubs of the rose family, related to the cherry, peach, almond and apricot. The fruit of the plum differs from that of the peach in having smooth skin and an unwrinkled stone. Plums which are of small sugar content and are usually eaten raw are called plums, while those of large sugar content and which dry well are commonly known as prunes. The wood of the plum tree is close-grained and sometimes is important as timber. The sap is very bitter due to its content of hydrocyanic acid.

The wild plum (*P. americana*) is native to North America east of the Rockies. The common European species (*P. domestica*) is most important commercially. It is native to Asia and eastern Europe, and is now grown extensively in America. Japanese plums (*P. salicina*) are more recent importations into our country. The Canada plum (*P. nigra*) is a hardy species that dips down into the northern United States.

Poinsettia (*Euphorbia pulcherrima*). This showy member of the spurge family is grown for its brilliant scarlet bracts which are often more than a foot long and occur beneath the true flowers. Presenting a vivid contrast of red against all the rest of the plant which is green, the poinsettia is much in demand at the Christmas season. The cut stems give off a milky juice, and when used as cut flowers the stems are dipped into boiling water or burned to stop the flow of juice.

Poison Ivy (*Rhus* spp.). A shrub or vine of the cashew family and of the sumac genus, native to America and widely distributed. Its leaves are distinguished by having three leaflets. It bears tiny greenish-yellow flowers and these mature into whitish berries and hang on during much of the winter. Certain persons upon contact with the plant suffer poisoning which manifests itself in inflammation and blisters.

Pokeweed (*Phytolacca decandra*). A native American perennial of the pokeweed family. It grows rankly and from four to ten or more feet in height along roadsides and in waste places. The flowers are small and in bracted racemes two to eight inches long. In autumn purplish berries hang in clusters. Birds eat the berries, and they are probably harmless to man, though the seeds are commonly held to be poisonous. The root, however, is very poisonous.

Pomegranate (*Punica granatum*). A small tree of the myrtle family grown since early times especially in Asia, which is often regarded as the land of its origin. The fruit is about the size of an orange and has a thick reddish-yellow rind and contains an abundance of large seeds, embedded in a juicy subacid pulp. The pomegranate is grown to a limited extent in the southern United States. A drink, grenadine, is made from the pulp.

Poplar (*Populus* spp.). Hardy, quick-growing trees, closely related to the willows as is shown by the blossoms borne in catkins. The leaves are broad and leathery and set on long petioles. The wood is soft and weak and easily split. It is used for woodenware, crates and pulpwood. Poplars are among the first to grow after a fire, but they usually disappear before the longer-lived trees attain maturity.

The Lombardy poplar (*P. nigra italica*) is an imported tree used as an ornamental in America. The white poplar (*P. alba*), or silver-leaved poplar, is used more than it deserves as a shade tree. The cottonwood (*P. deltoides*), or "necklace-bearing poplar," is appreciated by Western settlers where it is often their only tree. Pollen-bearing cottonwoods are better as they do not yield the unpleasant "cotton." The trembling aspen (*P. tremuloides*) is a handsome tree ranging all over America. It is often called the American aspen. The balsam poplar (*P. balsamifera*) is abundant in western North America. A variety was known to the early Eastern settlers as the balm of Gilead. It is a tree of good habits and easily propagated.

Poppy (*Papaver* spp.). Annuals and perennials grown in our country as garden flowers and in Asia and Egypt as the source of opium. The Oriental poppy (*P. orientale*) bears large brilliant flowers of orange or scarlet. The Iceland poppy (*P. niducaule*) is a dwarf perennial with delicate crepey flowers. Corn or Shirley poppies (*P. Rhoeas*) are beautiful annuals always bearing single flowers. The opium poppy (*P. somniferum*) is a handsome annual whose flowers are often double and marked by thick petals.

Portulaca (*Portulaca grandiflora*). An annual garden flower related to purslane. It grows in hot, dry places and bears red, orange and white blossoms which may be either single or double.

Potato (*Solanum tuberosum*). A member of the nightshade family related to the tomato, tobacco and eggplant. It is a native of America, having been found from Colorado to Chile. It was introduced into Ireland in 1586 and later into other parts of Europe where it is now a staple crop. The potato plant bears white or purple flowers, and seed balls. Under cultivation the seed balls occur but rarely. The valuable tubers are borne on underground shoots. In the tubers are stored large quantities of starch and other matter. Under cultivation these edible tubers are much increased in size. The number of varieties of potatoes in the United States is said to exceed 600.

Primrose (*Primula* spp.). Garden and greenhouse plants with attractive foliage and beautiful flowers well adapted for growing in pots. Primroses also occur wild. *P. obconica* is one of the best of the cultivated primroses.

Privet (*Ligustrum* spp.). Ornamental shrubs of the olive family. They bear small white flowers and are attractive in any place. Landscape gardeners use privet widely for hedges and borders. The Amoor River is particularly good for a hedge. The common privet (*L. vulgare*) succeeds in the smoke and dust of cities and is much used in the eastern United States. The Japanese species (*L. japonicum*) is attractive for border plantings.

Pumpkin (*Cucurbita pepo*). A vine and its fruit of the gourd family, bearing large yellow blossoms and heavy yellow fruit weighing from a few pounds to fifty pounds. The fruit is fed to stock and is used by man as a vegetable and in making pies. The small boy enjoys making jack-o'-lanterns from ripe pumpkins. The plant is a native of America and was cultivated by the Indians.

Purslane (*Portulaca oleracea*). A troublesome garden weed and one often found in corn fields. The succulent stems are liked by pigs. In Europe it is cooked and eaten as greens. The flowers are small and yellow. The plant is related to the garden flower, portulaca.

Pussy Willow. See Willow.

Quack Grass (*Agropyron repens*). A troublesome weed in the northern United States and Canada. The fruiting spikes resemble those of wheat, although thinner. The grass was imported from Europe. It propagates from tough, matted underground stems, and new plants spring from the joints of these so-called "roots."

Quince (*Cydonia oblonga*). A small tree of the rose family, related to the apple and the pear. It is a native of Asia and was introduced into America in Colonial times. The flowers are white or pink and the fruit is hard and yellow when ripe. It is very acid and cannot be eaten raw. It is esteemed for making into marmalades and jellies.

Radish (*Raphanus sativus*). A garden vegetable of the mustard family, grown for its pungent edible enlarged root, which is usually eaten raw. The radish has been cultivated for 3,000 years in China. There are spring, summer and winter radishes, but the spring kinds are most popular. The wild radish (*R. raphanistrum*) is a weed of the northeastern United States and Canada. It resembles the cultivated radish, but lacks the enlarged root. The flowers are yellow while those of the garden radish are pink.

Ragweed (*Ambrosia* spp.). Annual and perennial weeds of the composite family. The ragweeds are unsightly weeds often abundant in grain fields and also in cultivated areas and in pasture lands. They are prolific producers of seed. The ragweed is also undesirable because it is a cause of hay fever.

Ramie (*Boehmeria nivea*). A fiber plant of the nettle family grown principally in the warmer parts of China and Japan. Although it can be produced in the southern sections of the United States, its cultivation has never been important. The flowers are small and greenish-white. The fiber taken from the shoots, which arise each year from the underground rootstocks, is soft and strong and nearly equal to silk in fineness. In our country ramie yarn is used chiefly for making gas mantles. In the Orient it is made into "grass cloth."

Rape (*Brassica napus*). An annual or biennial forage plant belonging to the cabbage family. It is a native of Europe and is now extensively grown in America. In the South it is a winter crop and in the North a summer crop.

Raspberry (*Rubus* spp.). A popular bush fruit found wild and cultivated in many parts of the temperate zone. Wild raspberries are commonly called "thimble-berries." Among the important species are the black raspberry, or black-cap (*R. occidentalis*) a native of America, large-seeded but of excellent flavor; the European red (*R. idaeus*); the American red (*R. strigosus*), widely cultivated and used for jams; the purple-cane raspberries, which are crosses between red and black berries.

Redbud (*Cercis* spp.). Small trees or shrubs of the pea family noted for their red flowers which are borne in clusters. Redbuds make good ornamentals but are not of much value otherwise. Three species are native to America: the Texas redbud, the California redbud and the common redbud or Judas tree which occurs from Ontario to Arkansas.

Redtop (*Agrostis palustris*). An important perennial grass grown in America but a native of Europe. It thrives in wet lands and in places lacking in lime. It is used in New England as a hay grass and elsewhere as a pasture crop.

Redwood (*Sequoia sempervirens*). A large evergreen tree found on the Pacific Coast of the United States. Trees older than the Christian era have been felled. The wood is light and durable and reddish in color. It is valuable for building purposes, especially in contact with the soil. The Government has purchased certain areas to perpetuate these noble tree giants.

Rhododendron (*Rhododendron* spp.). A genus of ornamental shrubs and trees of the heath family, grouped by botanists with the azaleas (deciduous), but by practical growers separated as evergreens into the genus *Rhododendron*. The great rhododendron, or great laurel (*R. maximum*) is popular with its broad leaves and many-colored flowers ranging from white to pinks and purples. It is the state flower of West Virginia. The western rhododendron (*R. californicum*) is resplendent with shining leathery leaves and rose-colored flowers. It is the state flower of Washington.

Rhubarb (*Rheum rhaponticum*). A perennial of the buckwheat family, native to Asia and grown widely in America for its edible leaf-stalks which are cooked and eaten as sauce or for pies. The plant is also known as "pieplant." The dried roots and rhizomes have medicinal properties.

Rice (*Oryza sativa*). An annual of the grass family grown for its seed which is one of the world's important cereals. Rice requires a wet place to grow, and fields are typically flooded with water. Rice has been grown since ancient times in the Orient where it today feeds about one-third of the entire human race. In the United States rice has been cultivated in the southern sections for over 200 years, and it is an important crop in Hawaii and in the Philippines. The plant grows from two to six feet high and bears panicles at the tops of the stems. In these the seed are contained. In our country, the fields are drained before harvesting and the rice is cut by a harvesting machine. Threshing is done after the kernels and straw are thoroughly dry.

Wild rice (*Zizania aquatica*) grows in swamps in North America and furnishes food for water birds. Formerly the Indians gathered it and beat out the kernels in their canoes as they paddled through the swamps.

Rose (*Rosa* spp.). Perhaps the most important of flowers, found wild and cultivated since ancient times. The rose is referred to in literature and history very often and rose culture has been written of for centuries. The rose is usually an erect or climbing shrub with thorny stems and single or double flowers which range in color from white to yellow and many shades of pink and red. The rose is principally used for decorative purposes, although attar of roses is an important perfume. Preserves are made of the fruits of certain species.

Some roses bloom more or less continuously while others blossom but once a year. Such roses as the Damask, Yellow Brier and climbers bloom in June. The hybrid tea, the hybrid perpetual, the baby rambler, the China and others produce blooms through the summer. One of the best-known wild species is the prairie rose (*R. setigera*) which produces pink flowers late in the season. Wild roses can be transplanted to the garden. Most of our common fruit trees and berries belong to the rose family (*Rosaceae*). New York, Iowa, Georgia and North Dakota have adopted roses as their state flowers.

Rubber Tree (*Hevea brasiliensis*). This tree supplies most of the rubber of commerce. Among other rubber trees are species of the genera *Manihot, Castilloa, Ficus* and *Landolphia*; but these are unimportant economically. It was originally found in the Amazon region of South America, but it has been taken to the East Indies and that part of the world with its well regulated rubber plantations now produces the bulk of the world's supply. The tree belongs to the same family as the castor bean and the poinsettia. The milky juice, or latex, dried, furnishes the rubber of commerce. The rubber plant is also grown as a small ornamental tree in houses.

Rutabaga (*Brassica campestris*). A winter turnip resembling the ordinary turnip but with denser flesh and a longer, more slender root. The root is used as a food for the table and for feeding to livestock.

Rye (*Secale cereale*). A hardy annual of the grass family, closely related to wheat.

Rye did not appear as early as other cereals, but was first known in southeastern Europe. As a grain, rye is made into the black bread of Europe. In America rye bread is made of a mixture of rye and wheat. The plant is often used as a cover crop and plowed under as green manure. The straw is useful for making hats, paper, mattresses and for packing purposes.

Wild rye, or lyme grass (*Elymus* spp.), occurs in the United States and makes pasturage. It is also cut as a meadow grass.

Sage (*Salvia officinalis*). A perennial herb whose leaves are used for flavoring sausages, cheeses and dressings. It is a native of Europe and most of our sage is still imported, although it is often grown on a small scale in kitchen gardens.

Sagebrush (*Artemisia* spp.). Shrubby wormwoods of the composite family which cover thousands of acres of arid land in the western part of the United States. The plants have a pungent odor somewhat resembling that of sage, hence the name. It is eaten to a limited extent by cattle and sheep and often furnishes the only fuel available. Nevada has chosen the sagebrush as a State flower.

Salpiglossis (*Salpiglossis sinuata*). An attractive annual garden flower resembling the petunia but with the blossoms tinged with a glint of gold. It is often called the "orchid of hardy annuals."

Salsify (*Tragopogon porrifolius*). A garden biennial related to chicory and grown for its tapering edible root. It has an oyster-like flavor when cooked. The plant is hardy and may be left in the ground over winter.

Sandalwood (*Santalum* spp.). Certain Oriental trees much used in ornamental carving and cabinet work. The best known is *S. album*. The wood is close-grained and fragrant and articles made from it are highly prized.

Sapodilla (*Achras sapota*). A tree of the family *Sapotaceae*, native to tropical America. It bears a juicy edible fruit about the size of a small orange with a reddish-brown skin and dark yellow flesh. The milky latex of the tree is important as the source of chicle from which chewing gum is made. The trees are tapped as are rubber trees. Sapodillas have been grown to a limited extent in Florida.

Sapote (*Lucuma mammosa*). A tropical tree cultivated for its large sweet-flavored fruit which makes an excellent jam. The fruit is also known as the marmalade plum. It is somewhat like a ripe pear in taste. The single large seed yields a rich oil used in the tropics for confectionery purposes. The closely related white sapote is *Casimiroa edulis*.

Sassafras (*Sassafras* spp.). A tree of the laurel family noted for its aromatic roots and bark which are made into tea and medicinal preparations. In forests the trees reach a height of over one hundred feet and are valuable for their lumber. The sassafras occurs throughout the eastern part of the United States and in Ontario. Sassafras wood is good for posts and for other places in contact with the soil.

Sensitive Plants. Many plants are sensitive to the touch, but the plant commonly referred to as the sensitive plant is the *Mimosa*. This native of Brazil is cultivated in gardens and the leaves droop upon the touch of the finger or upon jarring the plant. Mimosas have small pink flowers.

Sequoia. A genus of mammoth evergreen trees of the Pacific slope of the United States, including the redwood (which see) and the "big trees" (*S. gigantea*) of California. Mature trees attain a height of about 275 feet. One standing is 325 feet, and another fallen tree is more than 400 feet. The lumber is very valuable.

Service-berry (*Amelanchier* spp.). A genus of trees of the rose family, closely related to the apple. The genus is represented in many parts of the Northern Hemisphere and in northern Africa. The best known species is the American or Eastern service berry (*A. canadensis*) known also as the June-berry and the shad-bush. The white flowers and the red berries which follow are very attractive. Birds feast on the berries. The western service-berry (*A. alnifolia*) of the western United States and Canada is esteemed for its large berries which grow to a diameter of an inch.

Shamrock. The floral emblem of Ireland, the shamrock, is the name given to various plants including clovers, wood sorrel, water cress and nonesuch. St. Patrick's shamrock is said to have had three leaves which were said to represent the Trinity. The plants commonly sold on St. Patrick's Day are white clover, a species of hop clover and wood sorrel.

Shepherd's Purse (*Capsella bursa-pastoris*). A weed of the mustard family, growing from six to twenty inches high and bearing white flowers and seed pods which look like tiny purses.

Sisal (*Agave sisalana*). A perennial tropical plant closely related to the century plant and grown in many parts of the tropics for its hard fiber. It is not to be confused with henequen, sometimes wrongly called sisal. The fiber is made into ropes and twines. Some is used as binder twine.

Skunk Cabbage (*Symplocarpus foetidus*). One of the earliest flowers found in wet areas. It belongs to the arum family. The spathe-covered flowers appear before the leaves. The plant has a disagreeable odor which gives it its name.

Snapdragon (*Antirrhinum* spp.). An annual or perennial garden flower of the figwort family. The flowers are interesting because upon pressure on the sides they open like a mouth. A wide range of colors is displayed in the flowers.

Sorghum (*Holcus sorghum*). A grass cultivated since ancient times in the Old World and introduced into America by the early colonists. It is valuable both for its stalk and for its grain. The principal groups of sorghum include the sweet sorghums, those like Kafir and milo and grown for their grain, the fine-stemmed sorghums and the coarse-stalked varieties which are used as broom material.

Sorrel (*Rumex acetosella*). A weed deriving its name from the German word for "sour," referring to the taste of the leaves.

Southern Moss (*Tillandsia usneoides*). A plant of the pineapple family, not a moss. It is sometimes called Spanish moss, but it does not grow in Spain. It occurs in the eastern Southern States where it grows on dead or living trees, hanging from the limbs. The plant is used as stuffing in upholstery.

Spicebush (*Benzoin aestivale*). A shrub, known also as feverbush and wild allspice, of the laurel family. It grows from four or five feet to as high as fifteen feet in cultivation. It has bright green leaves which turn yellow in autumn. The flowers are small and yellow. The berries are crimson and very spicy and much sought by the birds. The benzoin of druggists is derived from the leaves and berries of a plant of this group.

Spinach (*Spinacia oleracea*). The most important garden plant grown for greens. It is a hardy annual of the goosefoot family. It was first grown in western Asia in ancient times and was first known in Europe in the fifteenth century. It is now grown extensively all over the civilized world. Spinach furnishes valuable vitamins and minerals including iron.

Spirea (*Spirea* spp.). A genus of shrubs much used for planting. Among the best known is the bridal wreath (*S. prunifolia*) with its long slender branches and profusion of white flowers. Van Houtt's spirea (*S. Vanhouttei*) is very showy and its foliage is attractive all summer. Thunberg's spirea (*S. Thunbergii*) is a popular early species with delicate foliage and flowers.

Spring Beauty (*Claytonia virginica*). An early spring wild flower of the purslane family found in moist woods and low meadows. The flowers are white tinged with pink to all pink. The plant springs from an underground tuber.

Spruce (*Picea* spp.). A genus of cone-bearing evergreen trees of the temperate and subarctic regions of which about a dozen are native to North America. The Sitka spruce (*P. sitchensis*) grows from California to Alaska. It attains a height of more than 200 feet. During the World War tall straight Sitka spruce was much in demand for airplane construction and this lumber was known as "airplane stock." Its principal use is for paper pulp. Some is made into lumber, but it will not resist moisture. An immigrant, the Norway spruce (*P. excelsa*) is popular in the eastern United States as an ornamental. Other spruces of the eastern section include the white spruce (*P. canadensis*), the red spruce (*P. rubra*) and the black spruce (*P. mariana*), all of which are useful for paper making and to some extent for lumber.

Squash (*Cucurbita* spp.). Bushy to trailing vine-like plants of the cucumber family, grown for their fruits which vary in size. There are two general classes, the summer and the winter squashes. The former are bushy plants with short stems. The winter squashes produce long trailing vines. The large rough leaves of the squash are borne on long hollow stems. The flowers are large and yellow.

Strawberry (*Fragaria* spp.). The most important small fruit crop in America, grown in Europe for about 500 years. Most of our present strawberries are the development of two native species, the Chilean (*F. chilensis*) and the Virginian (*F. virginiana*). The important improvement of the fruit started with the Hovey strawberry raised by Charles Hovey of Boston in 1834. The plants are low-growing and propagate from runners. The flowers are white and the seeds are borne on enlarged fleshy receptacles which form the so-called "berry." Most strawberries bear during a short season, but the so-called "everbearing" varieties produce fruits from early summer until autumn.

Sugar Beet. See Beet.

Sugar Cane (*Saccharum officinarum*). A tropical grass with many-jointed stems. It is probably a native of southern Asia or of islands near there. The plant grows from six to sixteen feet high. The stalks are juicy and furnish one of the world's principal sources of sugar. Seeds are infrequent and propagation is by cuttings. Sugar cane is today grown throughout the world in warm regions.

Sumac (*Rhus* spp.). Trees or shrubs of the sumac family, some of which are used for ornamentals. One undesirable member of the genus, the poison ivy, has already been described. The staghorn sumac (*R. hirta*) with its hairy branchlets and its dark red fruit heads is an attractive ornamental. The aromatic sumac (*R. aromatica*) is another desired ornamental, hardy and with handsome foliage. Poison sumac (*R. vernix*) with its drooping grayish white berries is a deadly poison. It grows only in swamps. The common smooth sumac (*R. glabra*) is common on roadsides and is desirable for planting.

Sundew (*Drosera* spp.). A genus of insectivorous plants of the sundew family, so named from the exuding drops on the leaves which glisten in the sun like dew. Sticky hairs on the small plants entrap insects which are digested by secretions of the plant.

Sunflower (*Helianthus* spp.). Annuals or perennials of the composite family, of which the best known is the larger annual sunflower (*H. annuus*). They are natives of America. In Canada a mammoth sunflower has been grown as a silage crop. The Jerusalem artichoke (see Artichoke) (*H. tuberosus*) is grown for its edible tubers, which are fed largely to swine.

Sweet Gum (*Liquidambar styraciflua*). A tree of the witch-hazel family known variously as red gum, sweet gum, liquidambar, star-leaved gum and alligator tree. The star-shaped leaves pass from the green of summer to crimson, lilac and scarlet in autumn. The flowers are knotty little bunches and the swinging burrlike balls contain winged seeds. These seed balls are noticeable in winter after the foliage has fallen. An aromatic gum exudes from wounds. The sweet gum is a favorite shade tree.

Sweet Pea (*Lathyrus odoratus*). A garden annual imported from Europe and grown for its handsome fragrant flowers which exhibit a wide range of colors and sizes. It belongs to the pea family.

Sweet Potato (*Ipomœa batatas*). A perennial garden vegetable grown for its edible root, of the morning glory family, native to South America and now extensively grown in the United States, especially in the southern sections. As a vegetable it ranks next to the Irish potato in value.

Swiss Chard. See Beet.

Sycamore (*Platanus occidentalis*). This tree is called also the buttonwood. It has its relative in Europe in the plane tree (*P. orientalis*), which has been introduced and has become common as a street tree all over America. The sycamore bark is thin and brittle and scales off to reveal chalky white branches. When the leaves are gone the seed balls, or "button-balls," hang on. The wood is tough and is preferred for butchers' blocks.

Syringa (*Philadelphus* spp.). A genus of ornamental shrubs of the saxifrage family, known also as mock orange. The lilac (which see) has the generic name Syringa, but this is another usage. The syringa is a hardy plant bearing numerous white sweet-scented flowers in late spring.

Tamarind (*Tamarindus indica*). An Old World fruit tree, evergreen, of the pea family and resembling the common locust in appearance. It grows in tropical areas. The seeds are embedded in a soft brown pulp in a pod. From this a refreshing cooling drink is made. The tree has been introduced to a limited extent in Florida.

Tangerine. See Orange.

Tapioca. See Cassava.

Taro (*Caladium colocasia*). A perennial of the arum family which has been cultivated since ancient times in the Orient. From the root the Hawaiians make a sticky fermented paste known as "poi." The young shoots and leaves are also cooked and eaten. The familiar elephant's-ear is the same plant. A variety has been grown in our Southern States under the name "dasheen."

Tea (*Thea sinensis*). An evergreen tree or shrub cultivated for its leaves which are brewed to make a beverage. Wild tea trees grow to a height of thirty feet, but in cultivation it is desirable to prune the plants to a convenient height for picking the leaves. The flowers are ivory to rose colored and seed pods contain three round seeds. Tea was known in China as early as 2700 B.C. It was introduced later into Japan and more recently in India and the East Indies. All tea comes from the same plant, but black tea undergoes an oxidation or "fermenting" process before firing. Attempts have been made to grow tea in South Carolina. The world's supply comes from the Orient.

Teak (*Tectona grandis*). A tall timber tree of southeastern Asia. It belongs to the verbena family. Its yellowish brown lumber is valuable for shipbuilding and for wood carving and furniture. Teak ranks next to mahogany in value among the hardwoods.

Teosinte (*Euchlaena mexicana*). An annual grass found wild in Central America and Mexico and grown to a limited extent for fodder in the southern United States. By some, teosinte is maintained to be the ancestor of Indian corn (see Corn), and it will cross with corn.

Thyme (*Thymus* spp.). A genus of perennial shrubs of the mint family grown for their aromatic leaves which are used in cookery and for an essential oil which is secured by distillation. It is a native of the Mediterranean shores whence it has been introduced to various parts of the world.

Timothy (*Phleum pratense*). A perennial grass, native to Europe and introduced into America in Colonial days by Timothy Hansen who gave it its present name. Timothy has become the leading hay grass of North America. Its growth is bushy and the flowers are borne on the erect stems in the form of a spike of closely packed tiny blooms, resembling the cat-tail.

Tobacco (*Nicotiana tabacum*). A broad-leaved annual of the nightshade family, a relative of the potato and the tomato. It is native to Peru and was widely used by the Indians of both South and North America when the New World was discovered by Europeans. The name *Nicotiana* is in honor of the Frenchman Jean Nicot who introduced tobacco into France in 1559. In 1585 Sir Francis Drake brought tobacco to England and Sir Walter Raleigh took up smoking and made the practice popular. Tobacco is also used for chewing and as snuff. The tobacco industry is large and the United States leads. Usually tobacco is harvested by taking the entire plant, although sometimes the leaves are stripped from the stalk. Curing, stripping and grading are the customary processes in preparing tobacco for the market.

Tomato (*Lycopersicon esculentum*). An annual plant of the nightshade family, widely cultivated for its fruit which is the most recent important vegetable to be used as food. It was only in 1835 that the tomato was first sold for food. It is native to South America and for hundreds of years was known only as a curiosity. Even our grandparents regarded it as a garden ornamental and called the fruit the "love apple." Tomatoes are extensively used as a salad, for cooking and as a flavor and part of such condiments as catsup and chili sauce.

Trillium (*Trillium* spp.). Woodland wild flowers with all parts of the flower in threes, hence the name. The blossoms are usually white, but some species are purple or purplish red. It is one of the earliest of the spring flowers.

Tulip (*Tulipa* spp.). A native of the Near East and one of the most popular garden flowers. Tulips were grown in Holland as early as 1590 by Clusius, and a rage for the flower ensued which brought fabulous prices for the bulbs from which the plant is grown. Tulips are classed as those which bloom in April and those which flower in May and June. Darwin tulips are a tall, graceful, large-flowered race, exhibiting a great range of colors. *T. gesneriana*, often called the "cottage tulip" is a popular species introduced by way of Germany from the west of Asia. The tulip belongs to the large lily family.

Tulip Tree (*Liriodendron tulipifera*). A large, beautiful tree native to the eastern United States. It belongs to the magnolia family. It derives its name from its large greenish yellow flowers which resemble tulips. It is sometimes called "tulip poplar" but this is a misnomer (see Poplar). The wood is easily worked and is used for house and boat building. The blossom is the state flower of Indiana.

Tupelo (*Nyassa* spp.). A water-loving genus of trees of the dogwood family, known also as pepperidge, gum and by other names. Tupelo is the Indian name and the New England name is pepperidge. Woodsmen commonly refer to these trees as gums.

N. sylvatica occurs in the eastern United States and in Ontario and is often grown as an ornamental.

Turnip (*Brassica rapa*). A biennial vegetable of the mustard family of the same genus as the rutabaga (which see) grown for its edible root which is used as food for humans and for livestock. The flowers are yellow and resemble those of mustard.

Vanilla (*Vanilla* spp.). Certain tropical orchids from whose dried seed pods is extracted the vanilla of commerce used extensively to flavor cakes, perfumes, ice cream, tobacco and sauces. A native species of flat-leaved vanilla (*V. planifolia*) of Mexico and Central America is most widely used commercially. It is also cultivated in the West Indies and in Ceylon and Java. (See Orchid.)

Velvet Bean (*Stizolobium* spp.). An annual legume native of the Old World and grown extensively in the United States as a forage crop and for the beans which are made into meal and used as a stock food.

Venus' Flytrap (*Dionea muscipula*). An insect-catching plant of the sundew family occurring in North Carolina. Hairy, traplike leaves ensnare insects which are then slowly digested by secretions of the plant.

Verbena (*Verbena* spp.). Old-fashioned garden flowers of the vervain family. The sweet-scented *V. hybrida* is a favorite with bold, gayly-colored heads of bloom. The moss verbena (*V. erinoides*) is used for hanging baskets.

Vetch (*Vicia* spp.). With the exception of hairy vetch (*V. villosa*), the vetches are annuals grown as forage plants and for green manure. The common vetch (*V. sativa*) comes from Great Britain and the hairy vetch from Germany and Russia.

Viburnum (*Viburnum* spp.). A genus of useful hardy shrubs of the honeysuckle family widely used as ornamentals. The genus is well represented by native American species. The snowball (*V. Opulus sterile*) is a common species. The Japanese snowball (*V. tomentosum plicatum*) is a better plant, since the common snowball is very susceptible to the aphis. The high-bush cranberry (*V. Opulus*) is a popular border plant. Its red edible berry resembles the ordinary cranberry.

Violet (*Viola* spp.). Small wild flowers of the violet family ranging in color from white to pink and yellow and shades of blue. The violet does not possess fragrance but otherwise is almost a perfect flower. Violets occur wild in moist places but may easily be transplanted to the garden. Illinois, Wisconsin and Rhode Island have adopted the violet as their state flowers.

Virginia Creeper (*Psedera quinquefolia*). A trailing vine of the grape family with handsome dark blue berries. It is sometimes mistaken for the poison ivy but may readily be distinguished by its five-parted leaf, whereas the poison ivy has a three-parted leaf. It grows wild in the eastern part of North America and is planted as an ornamental.

Wahoo. See Elm.

Walnut (*Juglans* spp.). Valuable trees for their lumber, edible nuts and for shade. The black walnut (*J. nigra*) grows east of the Rocky Mountains and is prized for its wood which is used in furniture, in shipbuilding and in gunstocks. The round nuts are rich in oil. The butternut (*J. cinerea*), or white walnut, is a valuable lumber tree. In earlier days a stain from the husks was used in dyeing clothing known as "butternut jeans." The butternut is not as high a tree as the black walnut. The southwestern (*J. rupestris*), or Mexican walnut, grows in the Southwest and in Mexico. It has a smaller nut than the eastern species. The California walnut (*J. californica*) finds its chief value as a stock on which to graft the English walnut (*J. regia*). The name of the English walnut, *regia*, means "royal." It gave the genus name, *Juglans*, to the walnuts, from the Latin meaning "Jove's nut." Originating in Persia and northwestern India, this tree found its way to England. There the season does not allow the nuts to ripen, but they are taken green and pickled and eaten whole as a relish. From England the English walnut came to America where it is now an important crop in California.

Watermelon (*Citrullus vulgaris*). An annual vine of the gourd family, native to Africa and grown now most extensively in the United States. The fruit is a large berry in structure, often weighing fifty pounds or more. The outside is green or variegated and the inside is a sweet red pulp. Demanding warm growing conditions, the culture is restricted principally to the southern half of the United States. The fruit is eaten raw or made into pickles or preserves. In the Orient the seeds are eaten.

Wheat (*Triticum sativum*). An annual grass, probably originated in Asia, cultivated since prehistoric times. It bears starchy seeds in spikelets and these are prized all over the world as food, and it is today the chief bread food of the world. Winter wheat is sown in milder climates in autumn and is harvested in early summer. In severe climates the seed is sown in early spring and is harvested in late summer. This is known as spring wheat. Wheats are classified as hard and soft wheats for bread making. Durum wheat is very hard and is the best source of semolina, from which macaroni products are made. One-grained wheat, einkorn, is an interesting botanical form but is not grown extensively. Other kinds of wheat include Polish wheat, spelt, emmer, poulard wheat and club wheat. More than 200 distinct varieties of wheat are grown in North America. Wheat is the world's most valuable cereal crop.

Wild Carrot (*Daucus carota*). This wild flower and weed is known also as Queen Anne's lace and bird's-nest weed. It is usually considered to be the same species as the common cultivated carrot (which see).

Willow (*Salix* spp.). A genus of shrubs and trees of the willow family found over a wide range from the arctic regions southward. In the coldest regions the plants are often only two or three inches in height but with the typical catkins and narrow leaves of the willow. In warmer places the willow becomes a tree as high as 120 feet and three feet in diameter. The wood is soft and not useful for lumber. The willows are valuable for holding the soil along the banks of streams, their favorite habitat. The bark and the young shoots, or osiers, are used widely for basket making and wickerwork. The imported white willow (*S. alba*) and the native black willow (*S. nigra*) are common species. The shrub pussy willow (*S. discolor*) with its furry catkins in spring is often used for decoration. The almond-leaved willow (*S. amygdaloides*) is distinguished by its broader leaves resembling those of the peach or almond tree.

Winterberry (*Ilex verticillata*). A shrub of the holly (which see) genus found in low areas in the eastern United States. The flowers are small and white and are followed by bright red berries which hang on after the leaves fall, and with care may be used for Christmas decorations. The plant is wrongly called "black alder."

Another species, the smooth winterberry (*I. laevigata*) has earlier ripening orange-yellow berries.

Wintergreen (*Gaultheria procumbens*). A creeping evergreen plant of the heath family and a relative of the mountain laurel. It has waxy white flowers and glossy foliage. The fragrant red berries are a favorite food for birds. From the leaves is extracted the oil of wintergreen which is used as a flavoring and in medicine.

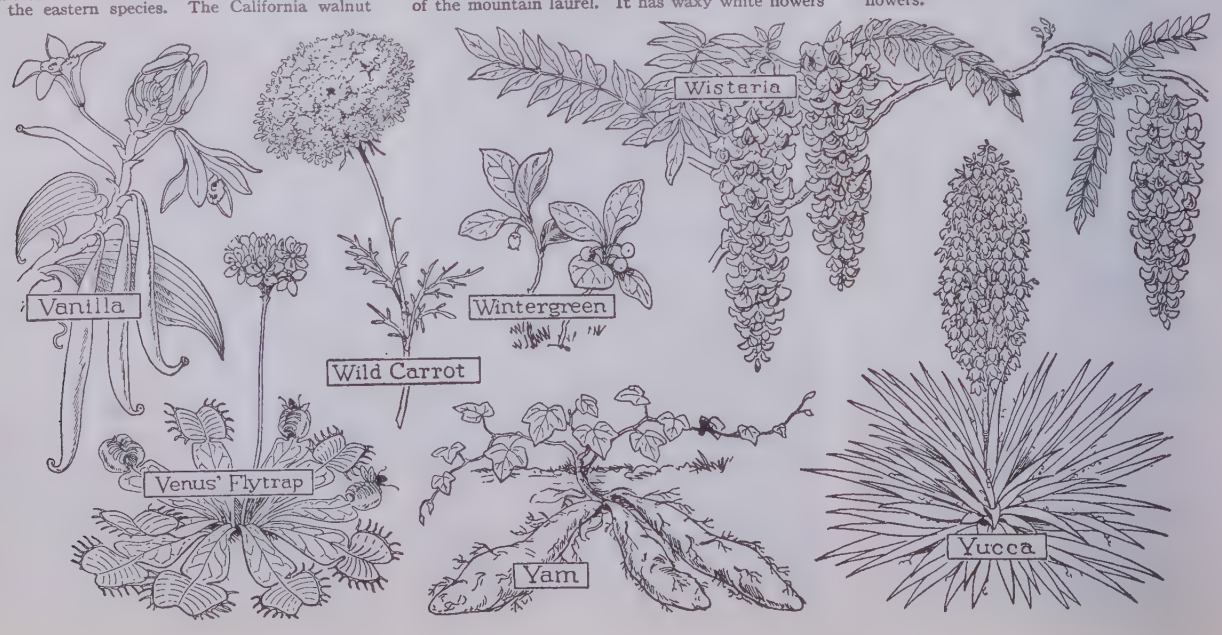
Wistaria (*Wistaria* spp.). The wistaria, named after Caspar Wistar, is also spelled "wisteria." It is a climbing shrub of the pea family and is prized for its handsome clusters of lilac-purple pea-shaped flowers. The Chinese wistaria (*W. chinensis*) is a popular species though the flowers are without scent. The Japanese species (*W. floribundia*) is a much grown scented flower, earlier blooming than the Chinese. An American species (*W. frutescens*) is seldom grown in cultivation.

Witch-hazel (*Hamamelis virginiana*). A many-stemmed shrub or small tree of the eastern United States. The flowers appear late in the season just before the leaves fall and resemble golden streamers. They curl up and remain through winter. Among the flowers are the seed pods which have the ability to shoot out their seeds for considerable distances. The witch-hazel is often used as an ornamental. From the leaves and twigs an extract is obtained which is used as a tonic and as a lotion.

Witloof Chicory. See Endive.

Woodbine (*Lonicera periclymenum*). The common name for the European honeysuckle. (See Honeysuckle.)

Yam (*Dioscoreaceae*). The term is sometimes wrongly applied to sweet potatoes. The yam belongs to another family and is a climbing plant of the tropics, grown for its edible root which may reach a weight of 100 pounds, although the larger varieties are not as valuable for food.



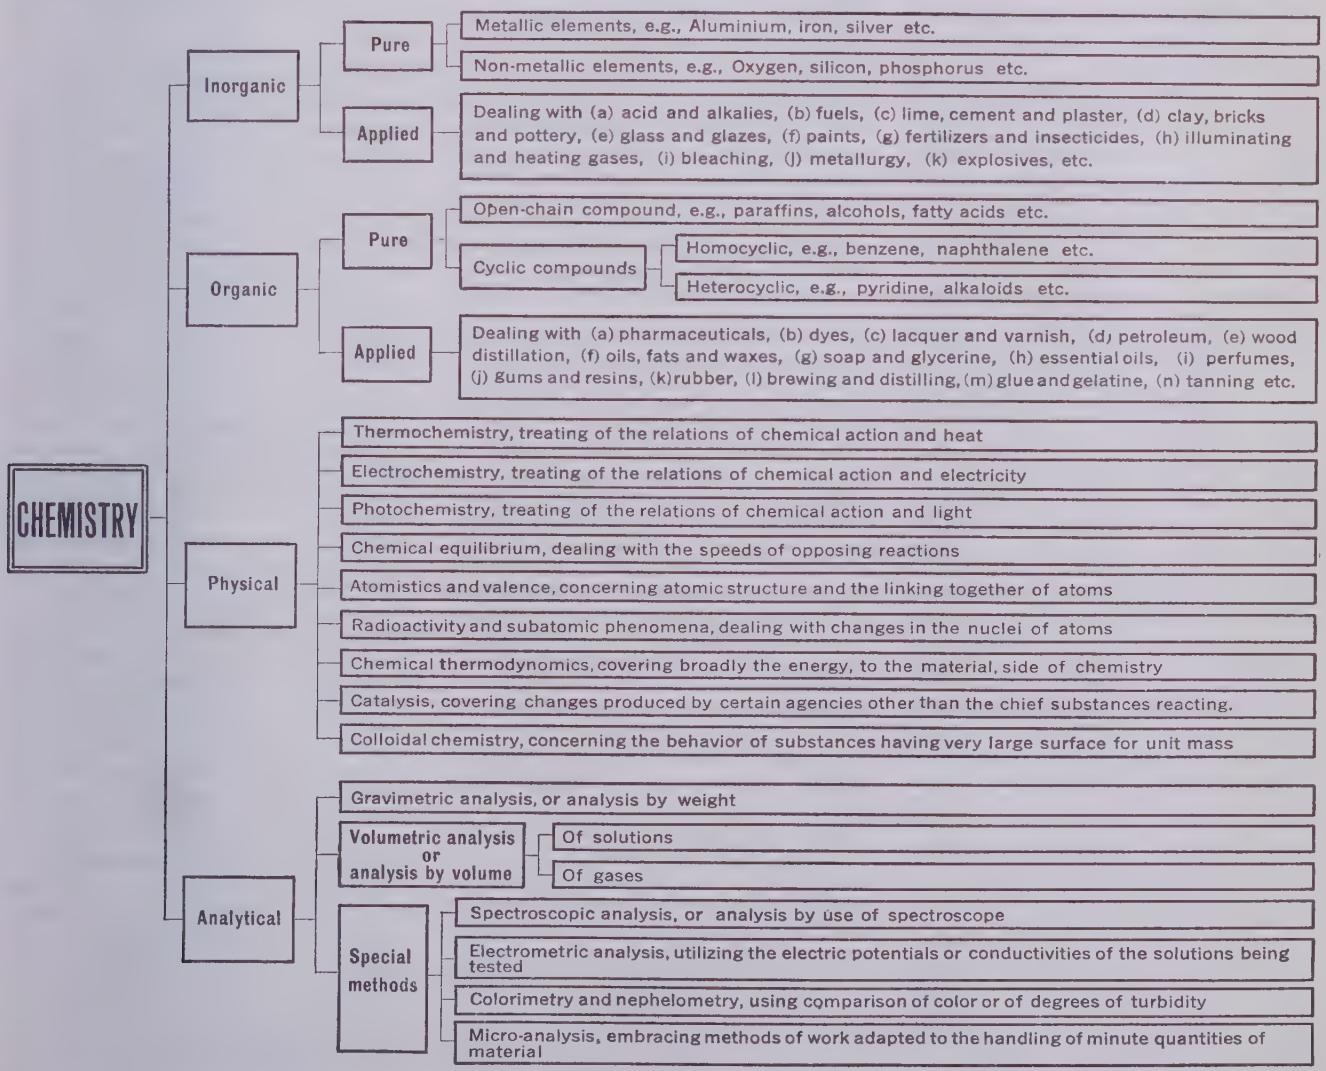
Yarrow (*Achillea millefolium*). A common perennial weed of the northern hemisphere, named for Achilles who is said to have discovered it. It is sometimes cut as a hay crop and often occurs as an impurity in timothy and clover seed. A tonic is made from the plant leaves and flowers.

Yeast (*Saccharomycetes*). Microscopic single-celled fungi which reproduce rapidly with food, moisture and proper temperature conditions. They secrete enzymes which break up sugar into alcohol and carbon dioxide in alcoholic fermentation. Yeasts are used in bread making to make the bread rise. Commercially yeast is sold as dry, compressed and liquid.

Yew (*Taxus* spp.). Evergreen trees or shrubs of the yew family with flat leaves or needles, darker green above and paler green below. The fruit is cup-shaped enclosing a bony seed. The fleshy covering is red. The western, or Pacific yew (*T. brevifolia*) furnishes wood used in making canoe paddles and in cabinet work. The American yew (*T. canadensis*) is a low shrub known also as ground hemlock. It is used for decorative wreaths.

Yucca (*Yucca* spp.). A genus of plants of the lily family with long, pointed leaves on a woody stem and bearing white flowers in terminal clusters. The yucca is native to the southern United States. Adam's needle (*Y. filamentosa*) is said to have been used by Adam in the Garden of Eden to sew the first garments. It bears an edible fruit known as the "datile." The Joshua tree (*Y. brevifolia*) is a branching species found in the Mohave Desert. It was named by the Mormons. The Mission Bells (*Y. Whipplei*) of California is an attractive plant with beautiful drooping, bell-shaped blossoms.

Zinnia (*Zinnia* spp.). A showy annual garden flower, member of the composite family. A common species which has been highly developed for flowers is *Z. elegans*. The Mexican zinnia (*Z. haageana*) is a dwarf form which bears hundreds of small orange flowers.



CHEMISTRY

WE SPEAK of inanimate nature, or the mineral world, and of animate nature, the world of plants and animals. The materials and substances that make up these two worlds, and the changes that the substances may undergo, were long ago assigned for treatment to *inorganic chemistry* and *organic chemistry* respectively; and this old classification is, broadly speaking, still a true one today. This time-honored separation is based upon the kind of matter that is being studied.

Many theories about matter and chemical change have been developed, and later improved or else discarded in favor of better theories. In such theoretical studies, the physical as well as the chemical characteristics of matter must be considered, and so has grown up the great division of chemistry called today *theoretical* and *physical* chemistry. Here belong subdivisions dealing with *atomic theory*, *atomic structure* and *radioactivity*, which will be mentioned later. One far-reaching theory discusses matter in the *colloid* condition, in which the forces at such interfaces as that between a solid and a liquid play an important rôle (*colloid* and *capillary* chemistry). *Chemical equilibrium*, including as in physics, both statics and kinetics, and the rules, such as the *phase rule*, which govern equilibrium, form another branch of physical chemistry. When matter changes, not only does its substance change, but its energy changes also. Very often the energy change is the more important of the two. As further divisions of physical chemistry we therefore have *thermochemistry*, *electrochemistry* and *photochemistry*, dealing respectively with the relations of chemistry to heat, electricity and light. As Sir J. J. Thomson has said, there is no longer any clear borderline dividing chemistry and physics. The fact that physics has made more progress in the last three decades than any science ever has in any like period of time, is now enabling chemists and physicists to find out the reasons for those fundamental changes of chemistry which have to do with the binding of atom to atom and which are studied under the name of *valency*.

Analytical chemistry is a division based not on the materials concerned, nor on the theories about them, but primarily on the processes used. Broad subdivisions of this are *qualitative analysis*, which finds out what substances are present; and *quantitative analysis*, which finds out exactly how much. This latter may be done either by measuring weights (gravimetric analysis), or measuring volumes (volumetric analysis). Other subdivisions include: (according to materials) gas analysis, organic analysis, analysis of food and drugs; and (according to method) microanalysis, colorimetric analysis, electrometric analysis, spectroscopic analysis.

In many schools in this country, chemistry is divided for convenience of study into inorganic, organic, physical and analytical chemistry, as above outlined; but these divisions overlap. Laboratory work is some-

The Divisions of Chemistry

This diagram made from an outline by the author gives an example of a possible way of dividing chemistry. As is always the case with classifications, the classes overlap. It will be found useful in giving a general view of the field of chemistry including some of the principal connections of the science with the work of the world.

times called "practical chemistry." Progress of the greatest "practical" value in industry is nowadays quite often the result of armchair theorizing. We are at present lacking more in guiding principles than in experimental facts.

Chemistry and the Work of the World. As civilization progresses, chemistry is applied to more and more of the activities with which mankind is busy. The branches of *applied chemistry* grow more and more numerous every day. Chemistry of drugs is *pharmaceutical chemistry*; of healing, *chemotherapy*; of life processes, *biochemistry* or *physiological chemistry*; of industrial processes, *industrial and engineering chemistry*; and so forth.

It is of interest to enumerate a few of the industries in which chemistry is a vital factor, and which, therefore, have a "chemistry" of their own: the chemical industry itself (acids, alkalies and other chemicals); bleaching; fuels; electrochemical industries; metallurgy; lime, cement and plaster; clay, bricks and pottery; glass; paint; lacquer and varnish; fertilizers and insecticides; dyes; drugs; illuminating and heating gas; petroleum; wood distillation; oils, fats and waxes; soap; glycerine; essential oils, perfumes and flavoring materials; turpentine and rosin; gums and resins; rubber; sugar; papermaking; explosives: tanning; glue and gelatine manufacture. All of these branches of applied chemistry have several textbooks of their own; but all are based on such fundamental material as that presented in the diagram.

THE FIELD OF CHEMISTRY

Chemistry is that science which is largely concerned with a study of the different species of matter and of the changes from one species to another. When iron rusts, or when charcoal burns, the products of these chemical changes are species of matter that are different from the original iron or charcoal. The different species or kinds of matter are called *substances*. Granite, and also gunpowder, are mixtures of at least three different substances.

Substances are recognized and identified often by their *physical properties*, such as color, density, boiling point, melting point and solubility. They can also be recognized by their *chemical properties*, such as combustibility, ease of rusting, or, generally, their *chemical reactions* or behavior toward other substances chosen to test them with.

Pure Substances. In studying the different kinds of matter (different substances), such as iron, charcoal, salt, sugar or niter, it is necessary first to prepare them in a pure state. To do this the chemist uses various processes. In *filtration* the insoluble solid matter is retained by a piece of unsized filter-paper, while the liquid passes through the paper and is collected as the *filtrate*. Instead of filter paper, unglazed earthenware may be used to filter drinking water. The pores in this are so small (in Pasteur filters) that even the minute microbes, some of which cause disease, cannot pass through.

In *distillation* a liquid, by raising its temperature, is converted into gas and is so separated from any substances that accompany it which are less *volatile*, that is, less easily gasified. In this way, for example, pure drinking water may be obtained on board ship from sea water, which contains difficultly volatile salts, including common salt, dissolved in it. The gaseous water (steam) is *condensed* to water again by passage through a cooled tube. It should be noticed that the changes from water into steam and vice versa are classed as *physical changes*, because analysis shows that steam and water consist of the same substance differing only in state, steam being in the gaseous state, water in the liquid, and ice in the solid state.

Sublimation refers to the distillation of solids. For example, sal-ammoniac and benzoic acid are purified by sublimation. *Lixiviation* and *leaching* refer to the dissolving out of a soluble substance from its admixture with an insoluble substance.

Physical Properties. The substance having been obtained in a pure state, a study may be made of its properties. Purity is extremely important; and chemists and physicists alike have in the past often wasted years of their lives in studying substances that were seriously impure and that could not, therefore, be expected to yield constant results.

Solubility. Among physical properties, *solubility* is one of the most important to the chemist. Liquids dissolve solids, other liquids, and also gases. If common salt be added to water, it dissolves, and, after stirring, the solution is said to be homogeneous because all samples, wherever taken, prove to be identical. Water is here the *solvent* and salt the *solute*. If more and more salt be added by degrees, the temperature remaining constant, a stage is finally reached at which the solution will take up no more salt. The solution is then said to be *saturated*, at that temperature, with common salt.

Concentration may be stated in any one of three ways: (1) Weight of salt contained in such a weight of the solvent; (2) weight of salt contained in such a weight of the solution; (3) weight of salt contained in such a volume of the solution. When the temperature is raised it is usually found that the solution can take up more salt. Tables of solubilities state the concentration of the saturated solution at a series of different temperatures. It is by making use of their differences in solubility that intimate mixtures of different solids can be separated into their components; for instance, radium bromide is separated from barium bromide by repeated *fractional crystallization*.

Most, but not all, solids are more soluble at higher temperatures than at lower. All substances seem to be slightly soluble in water, although in some cases the saturated solution is an exceedingly dilute one.

That gases dissolve in water is known to every one who has examined *soda water*, which contains the gas carbon dioxide in solution. If the gas is under pressure, the weight of it that the solvent will dissolve is proportional to the pressure (Henry's Law). Since soda water is *aerated* at several atmospheres' pressure, a portion of the gas tends to escape when the pressure is released. Gases are less soluble the higher the temperature, and can often, though not always, be completely removed by boiling the solvent. By ten minutes' boiling, for example, the gases dissolved from the air by ordinary water may be removed and the water thus rendered flat or insipid to the taste.

Molecular Hypothesis. In studying the physical properties of substances there is a hypothesis as to the structure of matter—the kinetic-molecular hypothesis—that has proved particularly illuminative. On this hypothesis, each substance is supposed to be built up of minute particles of its own material called *molecules*, all alike and each incapable of finer subdivision if the substance is to remain the same. In the solid, or crystalline, state of a pure substance, the molecules are arranged in rank and file in all three of the dimensions of space, and this gives rise to a regular external form, the crystal form, demonstrating the orderly internal arrangement. The molecules are vibrating, but they are not wandering about among their neighbors, except very occasionally. If the end of a bar of lead is coated by electroplating with gold, the gold *diffuses* into the lead only very slowly. In the case of liquids, the molecules are closely crowded together but they are able to wander freely among their neighbors, like people in a crowd. Consequently, diffusion in liquids is much faster than in solids. If a particle, for example, of charcoal, just large enough to be visible under the microscope is suspended in a liquid, such as water, and viewed under the microscope, the charcoal particle is seen to be moving about in an erratic manner. This movement is the *Brownian movement*, and it is caused by the unequal bombardment of the water molecules on opposite sides of the particle of charcoal. Study of the Brownian movement in recent years, using a "movie" camera with the microscope, has convinced the most skeptical chemists of the reality of molecules and of the truth of the molecular hypothesis. In the gaseous state of the substance, the molecules are at distances apart that are great in comparison with their own diameters, and are moving about in straight lines with great speed, each occasionally colliding with some other molecule or with the walls of the vessel. The miniature bombardment of the walls of the vessel by myriads of molecules is the cause of the pressure of the gas on the walls.

The Gas Laws. In agreement with this conception is the well-known fact that if a gas be compressed to one n-th part of its original volume, then its pressure is increased n-fold (Boyle's Law). For, plainly, the molecules, and therefore their impacts, will now be *n*-times as many as before. It is also a well-known fact of experiment that the pressure of an inclosed volume of gas varies directly as its absolute temperature, that is, its temperature measured from the absolute zero, which is $-273°$ C. (Charles' Law). This is accounted for by considering that the speed of motion of the molecules is increased as the temperature rises, and that the impacts of the molecules are therefore stronger. It is indeed strange that gases should all be precisely alike in conforming to these two laws, for in the case of solids and of liquids the behavior toward pressure and toward change of temperature is different for each substance. Gases, therefore, must have something in common which solids and liquids have not. What all gases have in common is this: that they contain, at like temperature and pressure, the same number of

molecules in equal volumes (Avogadro's Law). Since this is so, by weighing, under like conditions, equal volumes of different gases the relative weights of their molecules can at once be found. The *molecular weights*, compared with the weight of a molecule of oxygen gas taken as 32, of gases or of vaporizable substances are determined in this way.

Vapor Pressure. In the case of liquids, the crowding together of the molecules is much closer than in gases. If a gas be at a temperature lower than its *critical temperature*, however, it may always be compressed into a liquid. From the surface of a liquid, supposed to be placed, for example, in an empty closed vessel, some of the molecules are constantly escaping into the upper part of the vessel, where they behave like gas molecules, giving rise to a (gaseous) pressure there, known as the *vapor pressure* of the liquid. Some of these are constantly returning to the liquid, in the course of their wanderings, but their places are taken by newcomers from the liquid. As Lord Kelvin put it, the emigration is precisely equaled by the immigration. The vapor pressure, therefore, remains constant at any temperature. If the temperature is raised, this vapor pressure increases. For this reason, water in such a vessel, if raised sufficiently in temperature, might finally "burst its boiler."

Chemical Analysis. The chemical properties of pure substances may be studied by testing by experiments their behavior, under different conditions, both alone and toward other substances. In particular it may be discovered, for example, that red lead can be made to furnish the metal lead and the gas oxygen. The processes of finding out what substances or mixtures of substances are made up of are chemical analyses.

Qualitative Analysis concerns itself with the kinds of matter present, and *quantitative analysis* with the proportions by weight or by volume in which they are present. It has been found that all substances are made up from only about ninety different kinds of matter, called *elements*, combined in different ways. Thus sugar, alcohol, acetic acid, cotton and starch, although apparently so different, each contains only the three elements, carbon, hydrogen and oxygen in different proportions. All compounds containing only oxygen in combination with one other element are called oxides, as calcium oxide (quicklime), lead oxide (litharge). Those compounds containing chlorine in combination with one other element are chlorides, as sodium chloride (common salt) and so forth. In general, compounds with the termination *ide* contain only the elements whose language roots are in the names. Those whose names end in *ite* contain, besides, oxygen, as sodium chlorite; those ending in *ate*, more oxygen still, as sodium chlorate, while sodium *per*chlorate contains still more oxygen than sodium chlorate. The majority of the elements are metallic elements (metals), while only about fourteen are non-metallic elements (carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, chlorine, silicon and so forth.

Quantitative Analysis has brought out many of the most remarkable facts of chemistry that were entirely missed by the chemists of antiquity and of the Middle Ages. It is found, by weighing, that no matter can be destroyed, although one compound may be changed into another. This principle is called the *conservation of matter*. It will be discussed later, under "Combustion."

Quantitative analysis of different samples of the same pure substance brings out the fact that the composition of every pure substance is invariably the same, or, in other words, that the chemical elements combine in definite proportions by weight to form each particular compound. This observed regularity is known as the *law of definite proportions*. By analysis of different compounds made of the same elements, A and B, it is found, further, that the weights of B which, in the different compounds, are united with the same weight of A are related to each other in the ratio of small integers. This could not have been anticipated, and, because found, calls for explanation. The accepted explanation is furnished by the *atomic theory*.

The Atomic Theory. The atomic theory, in the form in which it was stated throughout the nineteenth and part of the twentieth century, said that the molecules of every compound are built up of units, called *atoms*, of the elements that are present, and that all the atoms of any one element are identical in material and weight. For simplicity, we may, for the present, take this older statement as correct; but we shall see below that not all chlorine atoms, nor all lead atoms, and so on, are identical in mass. Since it is true that there are but ninety different elements hitherto discovered by analysis of any kind, there are also but ninety species of atoms. The atom of each element is represented by a *symbol*, which represents both its name and also its weight; thus, Fe iron, 55.8; Cu copper, 63.6; O oxygen, 16.0; H hydrogen, 1.008. These symbols, and the atomic weights they represent, may be found in the table of chemical elements (p. 921). The atomic weight of the oxygen atom is taken, for certain reasons of convenience, arbitrarily as 16.0; and the weights of all the other atoms are compared with this. The hydrogen atom is the lightest, and the uranium atom, 238.2, the heaviest atom. The compound called cupric oxide is represented by the *formula* of its molecule CuO; and the compound called water by the formula H_2O, signifying that, in the water molecule, two atoms of hydrogen are bound up with one atom of oxygen, and so on. The chemical formulas and the names of some familiar chemical substances are: CO_2, carbon dioxide; CO, carbon monoxide; NaCl, sodium chloride (common salt); CaO, calcium oxide (quicklime); $CaCO_3$, calcium carbonate (makes up the greater part of marble, limestone and other products); H_2SO_4, sulphuric acid; K_2SO_4, potassium sulphate; $MgSO_4$, $7H_2O$, magnesium sulphate (Epsom salts); O_2, oxygen gas. The last formula tells us that a molecule of oxygen gas consists of two atoms. Since the weight of one oxygen atom is taken as 16, the weight of a molecule of oxygen gas is 32, and this explains the use of 32, mentioned above, as the standard in comparing molecular weights of gaseous substances. There are matters of greater importance to discuss here than the perfectly good question of how chemists know that a molecule of oxygen is O_2 rather than simply O, or O_3, or O_4. None of these suggested alternative formulas is absurd in itself, and the active, peculiarly smelling, *allotropic modification* of oxygen known as ozone has indeed the molecule O_3. The molecular weight, or formula weight, of cupric oxide is 63.6 plus 16.0, or 79.6; and of carbon dioxide 12 plus two times 16, or 44.

It will be seen upon reflection that this atomic hypothesis accounts perfectly for the experimentally found law of multiple proportions referred to above, as well as for the observed fact (law of combining weights) that the proportions by weight in which elements combine to form compounds can always be expressed perfectly by (usually) small integral multiples of particular numbers, one number belonging to each element. Furthermore, chemical formulas furnish us with an exceedingly useful shorthand. It has taken much thought and much work on the part of many chemists in the past to give us the formula of calcium carbonate, for example. Now that we have the formula clearly established, most of us can afford to forget the tedious historical steps which led to the adoption of the formula; and thus a very young man today can be put in command of more chemical knowledge than was within the ken of all the wisest of the ancients.

Reactions in Chemistry. *Reactions* are chemical changes. Hot iron filings will react with sulphur. If the supply of sulphur be very plentiful, the iron will not use it all. The *excess* of sulphur may be driven off by distillation. The two elements have combined to form ferrous sulphide, FeS, a black substance which has properties different from either iron or sulphur. The *equation* for this reaction, which is called a *direct combination*, is written $Fe+S \rightarrow FeS$, and it tells us that 56 parts by weight of iron unite with 32 parts by weight of sulphur to form 88 parts of ferrous sulphide. The reaction produces not only a new material substance, but also something else which is not material, namely a precise amount of heat, which is a form of energy, and must not by any means be neglected merely because it has no weight. The division of chemistry termed *thermochemistry* specializes in the study of heat of reaction.

A more complex reaction, which takes place in aqueous solution, is shown by the equation: $AgNO_3+NaCl \rightarrow AgCl+NaNO_3$ where we find the four "radicals," Ag, NO_3, Na and Cl, exchanging partners. Such a change is called a *double decomposition*. A group of atoms such as NO_3 that remain together throughout a series of reactions is called a *compound radical*. Such groups differ from molecules in that they cannot usually exist alone in the free state.

Radicals are classified into *positive* and *negative* radicals. In the above example, Ag and Na are each positive, while Cl and NO_3 are negative radicals. A compound containing both kinds of radicals is a *salt*—for example, silver nitrate, silver chloride, sodium nitrate, sodium chloride.

Those salts that have hydrogen for their positive radical are called acids, and their solutions have a sour taste and turn the blue coloring matter in litmus red. Those salts that have the group OH for their negative radical are bases, and their solutions have a soapy taste and feel, and turn red litmus blue;

example, sodium hydroxide. When an acid is mixed with a base in solution, the radicals H and OH combine to form water HOH, and the remaining positive and negative radicals, on uniting, constitute a salt. If the resulting solution has no action on litmus, the acid and base have "neutralized" each other.

Salts may also be formed in the dry way by the union of an "acidic oxide" such as carbonic anhydride with a "basic oxide" such as calcium oxide, $CO_2+CaO\rightarrow CaCO_3$. The oxides of the nonmetals are acidic, while the lower oxides of the metals are basic. The higher oxides of the metals, that is, those with more oxygen, are frequently acidic. An acidic oxide yields an acid when it combines with water, while a basic oxide yields a base.

The number of different chemical compounds known today is perhaps half a million; and the number of different chemical reactions is still larger. Many large volumes would be required barely to state the facts that are known. Some of the simpler facts about a kind of reaction called *combustion* may here be outlined, to show its importance in the study of chemistry.

Combustion. Combustion is a process in which elements unite with production of heat. Most familiar combustions involve oxygen as one of the elements concerned; but sodium will burn in chlorine gas to produce sodium chloride, and here no oxygen takes part. When pure charcoal, which is composed of nothing but carbon atoms, is burned in a plentiful supply of air, the charcoal disappears from view, and the only product is an invisible gas, carbon dioxide. Air itself is really a mixture of several invisible gases, mainly nitrogen (about four-fifths by volume) and oxygen (about one-fifth by volume). The carbon atoms that formed the original charcoal have not been destroyed; but each has united with two oxygen atoms, $C+O_2\rightarrow CO_2$. The accident that the product, carbon dioxide, is an invisible gas makes the experiment appear more mysterious than it really is. If we took the trouble to catch and collect all the carbon dioxide gas, we could, by taking sufficient pains, recover all the original carbon atoms. A candle, or kerosene, consists of compounds of carbon and hydrogen. When such compounds are completely burned, carbon dioxide, CO_2, and water, H_2O, are produced. Heat also is produced. When a candle is ignited and placed in a large glass vessel of air which is then closed, the vessel with its contents does not change in weight even though part of the candle disappears. This is because no atoms present in the candle or in the air are allowed to escape either in the form of water or carbon dioxide. The condensed water can be seen as a dew on the inner walls of the vessel. The candle soon goes out, however, because, as it progressively depletes the oxygen supply in the vessel, the rate of burning grows slower and slower until the heat furnished by the combustion is not supplied fast enough to make good the heat lost around the wick, and so the temperature falls below the kindling point. The vessel still contains unused or unburned oxygen to the extent of perhaps fifteen percent. It is just as rational to speak of burning the oxygen as of burning the candle.

Extinguishing Fires. The experiment described gives us a clue to the common sense of extinguishing fires. We can either, by water, reduce the temperature of the burning object below the kindling temperature; or else we can cut off, in part, the oxygen supply until oxygen forms less than fifteen percent of the gases which should feed the fire. This last can be done by diluting the oxygen of the air with a gas, such as steam, carbon dioxide or carbon tetrachloride, which does not support combustion. Water from the fire hose is converted to steam when it falls on very hot objects, and thus a stream of water is doubly valuable, for it reduces temperature and also furnishes an inert vapor. A fire in a ship's hold may be extinguished by releasing much carbon dioxide gas which, in ocean liners, is kept in steel tanks ready for the purpose. Instead of diluting the air with steam (vapor of water), one can less destructively spray such a liquid as carbon tetrachloride (from a portable brass pump) upon small conflagrations. This liquid is much more easily vaporized than water, and the vapor does not support combustion.

Rusting and Rotting. These chemical processes are to be regarded as slow combustions, but both require also the presence of moisture. Rotting leaves and stable manure produce heat fast enough to make them valuable for horticultural hotbeds; and rotting damp hay, through which heat does not escape rapidly, may finally kindle itself "spontaneously" into fast combustion.

Respiration of animals is a process enabling them to supply oxygen to their blood. This oxygen, by a process of slow combustion, furnishes heat and muscular energy to the body by oxidizing substances produced by digestion and assimilation from the food. The food is not burned directly, and the stomach is not a central heating plant, as is sometimes supposed. In this combustion of animal life for which the blood carries the oxygen, it should be noted that it is not the material products, chiefly carbon dioxide and water, which the animal desires, but the energy that arises from the chemical changes. The carbon dioxide must be eliminated in the exhaled breath.

A man can still keep alive in air in which a candle will not burn because of the dilution of the oxygen; and carbon dioxide gas is no longer regarded as especially toxic to animals. The commonest form of gas poisoning is by carbon monoxide gas, which arises in the combustion of carbon-containing compounds in an insufficiency of oxygen, and is, therefore, found in the exhaust gases of gasoline engines.

Volumes have been written on the subjects of combustion and respiration alone. In chemistry today we are embarrassed by the enormous number of facts. After obtaining its facts, every science endeavors to reduce chaos to order by classifying the facts. It is already comforting to know that there are only about ninety kinds of atoms. Chemists have classified and catalogued enormous numbers of compounds of these atoms and their reactions, and this vast multiplicity of facts tends to become unmanageable and indigestible. If we knew more about the structure of atoms themselves, perhaps we might secure the key to why these compounds are formed by the atoms and why the compounds react as they do.

Atomic Structure. For the reason just stated, the progress that has been made in recent years in the knowledge of atomic structure is very welcome, and of great importance because it tends toward simplification. By a more complete knowledge of atomic structure the young man of tomorrow may have once again placed in his hands more chemical knowledge than had all the wizards of yesterday; from a more complete understanding of the atoms themselves he may hope to be able to predict innumerable chemical facts as being just what were to be expected.

Electron and Proton. From the present day viewpoint, atoms are composed or built of two kinds of units or building stones, namely electrons and protons. Electrons may most conveniently be regarded as units of negative electricity, and protons as units of positive electricity; but these simplest units are not yet by any means fully understood. The charge of an electron is the same as the charge of a proton, but of opposite sign. The mass of the proton is 1,847 times greater than that of the electron, and the mass in both cases is entirely electromagnetic in origin. This means that matter is composed of electricity, and that electricity comes in unit packages of opposite electric signs. Further experimental study of electrons shows that each electron is accompanied and directed by a wave train of its own, and our future knowledge will doubtless grow out of a development of this finding with the aid of the new *wave mechanics*.

The Nucleus Atom. All the positive charge of any atom is concentrated in a very minute nucleus, which consists, in every case save that of the simplest atom, hydrogen, of a certain number of protons with not fewer than half as many electrons. The hydrogen nucleus consists of a single proton. The aluminium nucleus, for example, consists of 27 protons and 14 electrons. The net positive charge on this nucleus is therefore +13. Around this nucleus are 13 extranuclear or planetary electrons, revolving in orbits as do the planets round the sun, and held in their orbits not by gravity but by electrostatic attraction. The aluminium atom as a whole is therefore electrically neutral. Its mass resides almost entirely in its nucleus, since protons so greatly exceed electrons in mass. Aluminium is said to have the *atomic number* 13. Its nuclear charge is 13, and the number of its planetary electrons is 13. The atomic numbers of the chemical elements run from 1 for hydrogen, 2 for helium, 3 for lithium and so on, up to 92 for uranium. If all the elements are arranged in order of ascending atomic number, aluminium is the thirteenth element. Only two of the 92 elements up to uranium have not yet been discovered, namely, numbers 85 and 87.

Knowledge of the kinds of orbits in which the planetary electrons travel helps us to understand why atoms combine.

Certain groupings of the outermost electrons, especially groups of two and of eight, are particularly stable. We may say that two atoms will have an excellent motive or a good reason to combine if, by doing so, each can attain a group of eight for its outermost covering of electrons.

Helium is the only atom with but two electrons, each very firmly bound, in its outermost portion. Neon, argon, krypton, xenon

and niton have each exactly eight. All six of these atoms resemble each other very closely, despite their enormous differences in weight, because each is an inert gas and fails to combine with any other element. Since they already have such stable arrangements of electrons in their outmost portions as two or eight, they have nothing to gain, as it were, by combining. In the periodic system of the elements (see the table), we find them all in the same family, called Group O. In Group 1, we have a family of elements each of which has precisely one electron more, only loosely attached, than some very stable configuration of electrons. For this reason, all the elements of this family show chemical similarities due to this single oddly placed electron. Similar things may be said of the other groups or families of elements. The periodic classification was first set down as representing the experimental facts about 1868, long before the reasons for it were known. The Russian Mendélejeff, and the German, Meyer, working independently, discovered and announced what has come to be known as the "periodic table" in 1871. The atomic structure which explains the periodic classification has become clear only in the last few years.

PERIODIC CLASSIFICATION OF THE CHEMICAL ELEMENTS

Group	I A	I B	II A	II B	III A	III B	IV A	IV B	V A	V B	VI A	VI B	VII A	VII B	VIII			O
Period 1	H1																	He2
2	Li3		Be4		B5		C6		N7		O8		F9					Ne10
3	Na11		Mg12		Al13		Si14		P15		S16		Cl17					A18
4	K19	Cu29	Ca20	Zn30	Sc21	Ga31	Ti22	Ge32	V23	As33	Cr24	Se34	Mn25	Br35	Fe26	Co27	Ni28	Kr36
5	Rb37	Ag47	Sr38	Cd48	Y39	In49	Zr40	Sn50	Cb41	Sb51	Mo42	Te52	Ma43	I53	Ru44	Rh45	Pd46	Xe54
6	Cs55	Au79	Ba56	Hg80	La57 to Lu71	Tl81	Hf72	Pb82	Ta73	Bi83	W74	Po84	Re75	—85	Os76	Ir77	Pt78	Nt86
7	—87		Ra88		Ac89		Th90		Pa91		U92							

Valence. Atoms are bound into stable groups of atoms, or molecules, by the forces of *valence*. A carbon atom can bind to itself four hydrogen atoms to form a molecule of methane (marsh gas). Using the word valence in a metaphorical sense, we say that carbon has a valence of four, and hydrogen a valence of one. Valence is of two kinds, *covalence* and *electrovalence*. In explaining the existence of methane on the *electronic theory of valence*, we first note that hydrogen (atomic No. 1) has but one planetary electron, and that carbon (atomic No. 6) has six. Of these six, two are in orbits close to the nucleus, and therefore very firmly bound to it by electric attraction, while the remaining four are in outer orbits, and are called *valence electrons* because they are available to help in binding atoms together. Each of the four hydrogen atoms lends its electron to the carbon and itself gets a half share of one of the four valence electrons of the carbon. The carbon is thus successful in attaining a stable group of eight electrons, which it shares in four *shared pairs* with the four hydrogen atoms, each of which in turn has thus succeeded in securing a stable pair. To state the situation humanly, we might say that each atom has succeeded in attaining its ideal. The binding of atoms together by the sharing of pairs of electrons is called binding by covalence.

SOME COMMON VALENCES

I (univalent)	II (bivalent)	III (trivalent)	IV (quadrivalent)
H	Mg	Al	C
Na	Ca	Cr	
K	Sr	Bi	
Ag	Ba	Sb	
(NH_4)	Mn(ous)	As	
	Pb		
Cu(ous	Cu(ic)		
Hg(ous)	Hg(ic)		
	Fe(ous)	Fe(ic)	
	Sn(ous)		Sn(ic)
	Zn		
	Pt(ous)		Pt(ic)

This short table gives a few common valences. Metals with two valences typically exhibit the lower in the -ous compounds and the higher in the -ic compounds, for example in mercurous and mercuric salts. Some elements have other valences, for instance, antimony (Sb) has also a valence of V. Vanadium (not given here) has valences of II, III, IV, and V. A study of the Tables beginning on page 921 will reveal all the known valences.

In binding by electrovalence, lending, borrowing and sharing of electrons does not take place. Instead, one atom gives up one or more of its own electrons, and another atom takes full possession of what is given. Thus sodium (atomic No. 11) has eleven planetary electrons, arranged in stable groups of two and eight, with only one valence electron. Chlorine (atomic No. 17) has 17 planetary electrons, arranged in the atom in stable groups of two and eight, with seven in the outermost or valence group When a sodium atom combines with a chlorine atom, it gives to the chlorine atom its valence electron. The sodium atom, formerly neutral, therefore becomes singly charged positively, and is now called sodium ion, and written Na^+. The chlorine atom, formerly neutral, becomes singly charged negatively because it has acquired a gift of an electron; and it is now called chloride ion, and written Cl^-. In a crystal of solid sodium chloride there are an equal number of these ions, built together in such a way that around each sodium ion are six chloride ions each at the same distance from the sodium; and, around each chloride ion, six sodium ions each at the same distance from the chloride ion. The arrangement of atoms in such a simple crystal as sodium chloride can be found by studying the scattering by the crystal of a beam of light of very short wave length, or, in other words, by the *X-ray reflection method.*

The Ionic Theory of Solution. In view of the fact that sodium chloride is built up of ions, it does not appear very unreasonable that these ions should persist when sodium chloride is dissolved in water. The thought that aqueous solutions of acids, bases and salts contained the individual radicals of these substances, electrically charged and swimming free in the form of ions, was first put forward in 1887. This is today the accepted theory, and the reactions used in qualitative analysis of aqueous solutions are regarded as the reactions of the individual ions of the salts studied. In many non-aqueous solutions, the ions of salts remain bound to their partners, and such solutions do not contain free ions.

The Atomic Nucleus. Up to the year 1896, all the known reactions of chemistry were those which were due to changes of the valence electrons of atoms, which are the outermost of all. In the years since 1896 it has been found that all atoms above No. 81, and also a few others, may have unstable nuclei. When an atomic nucleus spontaneously goes to pieces we have the phenomena of *radioactivity*, as exhibited by radium, thorium, uranium and so forth. Such a nucleus usually breaks into only two pieces, namely a residue; and either (a) an alpha particle or (b) an electron. An alpha particle is nothing else than the nucleus of a helium atom or, in other words, a helium atom (atomic No. 2) carrying two positive charges because it has lost its two planetary electrons. These alpha particles are expelled with very high speed from the radioactive nucleus out of which they come, and are called *alpha rays*. In cases where the radioactive nucleus ejects an electron, we have *beta rays*, which consist of a stream of very swiftly moving electrons. Some of the planetary electrons of the atom are always jerked out by the radioactive cataclysm, and therefore beta rays are not exclusively of nuclear origin.

The Radioactive Disintegration Law. Because, in an alpha-ray change, the nucleus loses two positive charges, the atomic number of the radioactive atom goes down by two; and the resulting new atom has an atomic number two less. In a beta-ray change, the original nucleus loses one electron, and so gains one unit of positive charge; and the new atom brought into being has an atomic number one higher.

Artificial Disintegration of Nuclei. Because of the enormous energy with which alpha particles are expelled from the radioactive nucleus, they are the most energetic entities available in the laboratory. Rutherford has used them as missiles to shoot at the nuclei of other atoms to see if he could break them. In this way he has succeeded in knocking protons out of a dozen different sorts of atoms, all of low atomic number. What remains after the target nucleus has lost a proton is certainly not the original nucleus, but that of a new atom. Changing at will one atom into another is *transmutation*, and Rutherford has succeeded where the alchemists failed.

Isotopes. The chlorine atom has the atomic number 17. Its nucleus has a positive charge of +17. This could be made up of 35 protons and 18 electrons; or of 37 protons and 20 electrons, or in other ways. As a matter of fact, it is found by the experiments of *positive ray analysis* that some chlorine atoms weigh 35 and others 37. When we weigh chlorine atoms by the older methods of analysis we find 35.46. But this is merely an average value, and it tells us, by arithmetic, the proportions of the two chlorines, Cl^{35} and Cl^{37}, that are mixed together. Isotopic forms of an element have the same nuclear charge, but different masses, in typical cases. Since the charge governs the number and arrangement of the planetary electrons of the atom, on which depend all the ordinary chemical properties, it follows that isotopic forms are identical chemically. The isotopes of lead were found by the entirely different methods of radioactivity, and are among those known best and longest.

SUBDIVISIONS OF CHEMISTRY

In its treatment of the various forms of matter, chemistry divides itself into the two great branches of inorganic and organic chemistry.

Organic Chemistry. The latter is so called because it originally dealt with the substances that are found in the organic vegetable and animal kingdoms. Practically most of these substances contain carbon, so that organic chemistry is nowadays the chemistry of the carbon compounds. As the number of known organic compounds is well over 200,000, the subject is a large one, with a very voluminous literature, increasing year by year in yearly as well as in total volume.

Carbon. The valence of carbon in most of its compounds is uniformly 4, a regularity which simplifies matters considerably at the outset. Carbon atoms are found to have the faculty of linking themselves together to form chains and rings. In this faculty carbon is exceptional among the elements, and for this reason no other element approaches carbon in the multitude of its compounds so as to merit the treatment of its compounds as a separate branch of chemistry. The attaching of carbon atoms to each other does not utilize all four of the available valences, and the unoccupied valences are therefore able to attach to the molecule such other elements as hydrogen, oxygen, nitrogen and so forth.

It is found that the same grouping of elements recurs as part of a complex molecule; and all substances that possess the same group somewhere in their molecule are fortunately found to show the same reactions in virtue of the presence of that group. Thus, all the compounds containing the group CH_2OH are classed as primary alcohols; those with the group CHO are aldehydes; those with COOH are acids; those with the group

O
‖
—C—attached to carbon atoms on both sides, are ketones; and so on. The fact that all primary alcohols, all aldehydes, acids and so forth, behave chemically more or less alike makes it possible to bring order out of the chaos of organic compounds, since the typical groupings of atoms are comparatively few in number.

Hydrocarbons. Many important organic compounds contain only the elements carbon and hydrogen. These are called the *hydrocarbons*, and include marsh gas (CH_4), acetylene (C_2H_2), benzene (C_6H_6) and the components of rock oil, which is a mixture of many hydrocarbons.

Carbohydrates. Another set of organic compounds contains only the three elements carbon, hydrogen and oxygen, the latter two in the same proportion as in water, namely, two atoms of hydrogen to one of oxygen. These are the *carbohydrates*, and include grape and fruit sugars ($C_6H_{12}O_6$), cane, malt and milk sugars ($C_{12}H_{22}O_{11}$), the starches and cellulose [$(C_6H_{10}O_5)_n$], which last is the structural material of the vegetable world. The fats and oils, common alcohol, glycerine, and acetic, citric and tartaric acids contain only carbon, hydrogen and oxygen.

When to these elements is added nitrogen as a possible constituent of organic substances, the list becomes a very varied one, including nitroglycerine, nitrocellulose or guncotton, aniline and a horde of dyes, and most of the alkaloids—substances of very powerful physiological action that occur in plants. Adding also sulphur, the vastly important proteins are included, some of which (the nucleo-proteins) may contain also phosphorus. Other than water, fats and mineral constituents, proteins constitute the building material of the animal body, and are necessary in the diet of animals.

Inorganic Chemistry, deals with ninety different elements and their compounds, including those of the mineral world. Its extent is in part indicated in the subjoined table of "Chemical Elements."

Physical Chemistry, or theoretical chemistry, deals with the reasons for the facts of organic and inorganic chemistry, and studies the energy side as well as the material side of chemical phenomena. It includes such branches as thermochemistry, electrochemistry, photochemistry, colloid chemistry and catalysis.

The selection and grouping together of the facts and principles of chemistry that bear on some particular topic give rise to such divisions as *physiological chemistry, agricultural chemistry, biochemistry* and *immunochemistry*. Such titles are, for the most part, self-explanatory.

Food

As defined by an act of Congress, food includes "all articles used for food, drink, confectionery or condiment."

THE CHEMISTRY OF FOODS

FOOD is anything which, taken into the alimentary canal, furnishes heat and energy to the system, repairs waste and builds tissue.

The common idea of food is confined to solid or semisolid foods having the above properties. Liquid foods are usually spoken of as drinks or beverages. Condimental substances, such as salt, pepper and spices, are generally segregated from the ordinary classification of foods. There is a legal definition of foods found in the act passed by Congress June 30, 1906, which is as follows:

"The term 'food,' as used herein, shall include all articles used for food, drink, confectionery, or condiment by man or other animals, whether simple, mixed, or compound." This comprehensive definition will be followed in this article.

Kinds of Foods. According to their predominant characteristics for nutritive purposes, foods are recognized as of the following kinds:

Nitrogenous. Food material containing nitrogen as a distinctive element. The common name *protein* is applied to this class of foods. Most of the true protein foods also contain sulphur as an essential ingredient. Examples of characteristic protein foods are found in lean meat, white of egg, gliadin of wheat, hordein of barley, zein of maize, and so forth. Among the liquid foods, milk contains casein, which is a most important ingredient, and albumin, a protein food soluble in cold water. Other forms of protein are insoluble in cold water but are soluble in salt solutions, alcohol and other solvents. By means of these various solvents proteins can be separated into different classes. Protein food is often described as a tissue builder, but this is not a strictly correct classification. Only certain tissues of the body, such as the muscle, the nerve and the brain, are composed largely of proteid.

Starch and Sugar. Carbohydrates form by far the largest bulk of human foods. They are typically represented by starch and sugar. There are many carbohydrates in foods, however, which are more or less useful but not important as regards quantity or digestibility. The so-called "woody" tissues and fiber in foods are composed of carbohydrates, but these are of more importance for the

nourishment of domesticated animals than for man. For practical purposes the term *carbohydrates* applied to human foods embraces only starch and sugar. These substances in a pure state are characterized by being free of both nitrogen and sulphur, which are, as above stated, the most distinctive constituents of protein. They consist solely of carbon, oxygen and hydrogen, the oxygen and hydrogen existing in the proportions to form water.

Kinds of Sugars. Sugars are of various kinds, the most important for human nourishment being cane sugar, which has the composition of $C_{12}H_{22}O_{11}$. Sugar is an abundant product of almost every plant. It is stored especially, however, in certain plants in such a manner as to become available for extraction. The principal sugar producing plants are the sugar cane, sugar beet, the maple and the sugar palm. Practically all the sugar of commerce comes from the sugar cane and the sugar beet. The amounts made from other sources are insignificant.

In addition to cane sugar and beet sugar there are other varieties of sugar derived from starch. Among these perhaps the most important for dietetic purposes is maltose. Maltose is a sugar derived from starch in the process of the sprouting of the grains containing starch, or by acting upon starch by sprouted barley (malt). The starch of cereal grains is largely converted into maltose by the ferments of the malt. Starch is also converted into sugar by the ferments of the digestive organism. The saliva begins this conversion and it is completed in the intestinal tract, especially in the small intestine. Starch is also converted into sugar by the action of a dilute acid at a high temperature, and the sugar thus formed is known as dextrose.

Glucose or dextrose, cane sugar and maltose are all valuable foods, furnishing particularly heat and energy. Starch, as such, is not available for nutritive purposes, being insoluble and incapable of assimilation. There are many other forms of sugar or sugar-forming substances found in plants, among them levulose, the companion of dextrose, found as levulon particularly in the dahlia, artichoke and certain cacti. When cane sugar is eaten or when it is treated with a dilute acid it is converted into a mixture of equal parts of dextrose and levulose.

Honey is sugar exuded by the blossoms of plants and collected and stored by bees, and consists chiefly of cane sugar which has been converted as described above by nature or the bees and hence is a mixture of approximately equal parts of dextrose and levulose.

Glycerides. Fats are also important foods, furnishing weight for weight a larger quantity of heat and energy than any other food product. Fats exist in various forms. When they are solid or semisolid at ordinary temperatures they are called "fats"; when they are liquid at ordinary temperatures they are called "oils." Among the fats some of the most important for food purposes are butter, lard and tallow; among the oils, olive, cottonseed, peanut and sesame. The fats are chemically known as *glycerides*, being a compound produced by the union of a fat acid and glycerine. In the fresh, pure state they contain but little free acid, but on standing for a long time larger quantities of free acid are found. The rancidity of the fat, however, does not depend solely upon its quantity of free acid, but upon other conditions due probably to bacterial or enzymic action. Warmth and light tend to render fats and oils rancid, while keeping them cool and in the dark tends to preserve them from rancidity.

Minerals. The fourth class of foods are those of a mineral character, namely, foods which are essentially composed of mineral substances. Among the most important of the mineral foods in the nutrition of man are phosphorus and calcium; these go to make up the greater part of bone tissue and are found as essential ingredients in many parts of the body. Phosphorus and calcium are not usually found in any concentrated form in food products, but are distributed in small quantities in nearly all foods. The phosphorus which nourishes the body is ingested usually in an organic combination and not as phosphoric acid. Certain food products, as, for instance, cereals and eggs, are particularly rich in organic phosphorus. Calcium is found in nearly all food products especially in milk and certain green vegetables.

Mineral substances other than phosphorus and lime are also useful to some extent in nutrition, as, for instance, iron, potash and soda, the latter being valuable more for their incidental properties than because of their occurrence in the tissues of the body. In other words, it may be said that the blood in order to perform its functions must have a certain saline content, without which its circulation and the carrying of food to all parts of the body would be impossible. These saline materials, must be regarded as essential parts of our food and should not be removed too rashly in the refinement of foods.

Vitamins. The discovery of vitamins, a comparatively few years ago, opened an entirely new field of investigation to the food chemist. Vitamins are compounds which act catalytically to make it possible for metabolic processes to take place which in their absence would be prohibited.

There is much to be learned still in regard to vitamins. Four, and possibly five, may be regarded as definitely established. The method of naming vitamins may be changed in the future but, at present, the common method is to use the letters of the alphabet.

Vitamin A is found abundantly in butter fat, milk, egg yolk, cod-liver oil and other fish oils, cabbage, lettuce, spinach and other leafy vegetables. It is found more generously in yellow-colored vegetables, as carrots, sweet potatoes and yellow corn, than in white corn and turnips.

Vitamin B is the anti-neuritic vitamin. It prevents the development of the disease known in Japan as beri beri, and here as polyneuritis. It is of tremendous importance in preserving health. It has lately been considered as a double vitamin, not only containing antineuritic principles, but also as protecting against pellagra. (The anti-pellagra factor in the United States is generally referred to as vitamin G). This gives it additional importance. It is found in the wheat bran and germ, the rice bran and germ, yeast, liver and milk, and in leafy vegetables generally.

Vitamin C protects against scurvy and thus has an importance which has long demanded the attention of investigators and dietitians. Especially is it important that foods that are carried on long voyages should be rich in this antiscorbutic vitamin. This vitamin is found in fruits of all kinds, especially in citrous products, milk, cabbage and green beans. If pasteurized milk is used, orange or tomato juice should be given daily. Vitamin C is easily injured by pasteurization due to heat and oxygen.

Vitamin D, the antirachitic vitamin, is the active principle which protects against rickets. This is an interesting vitamin because its effects are duplicated in the action of the ultra violet rays of the sun, carbon light and mercury vapor lamps. Patients suffering from rickets are benefited by being exposed to those radiations. Foods such as dried milk which are subjected to the rays of the sun, or of the lamps above mentioned, become charged with additional quantities of this vitamin. Such foods are called "irradiated," and are now coming into use in the treatment of rickets. This vitamin is found in fresh foods, milk, cod-liver oil and liver diets, fruits and vegetables. It regulates the assimilation of calcium and phosphorus.

Vitamin E, the separate existence of which has not yet been fully established, seems to be concerned with reproduction and tends to stimulate the reproductive organs. This vitamin exists in great abundance in the germ of wheat.

Nearly all wholesome foods, especially of vegetable origin, are rich in vitamins. If we select natural, wholesome foods which are not refined nor manipulated in any way, we shall secure a reasonable amount of vitamins for all necessary metabolic processes. Vital organs are also rich in vitamins. The liver, pancreas, ductless glands and gonads have valuable properties of this kind. They are also powerful healing agents for diabetes, anemia and goiter.

Condimentals. Condiments are useful more for their effect on palatability than for purposes of pure nutrition. Palatability, however, has important relations to digestion, and hence condiments are properly classed as foods. Most condimental substances have some nutritive properties, containing as they do more or less starch, sugar, protein and fats. Vinegar, of which the most important ingredient is acetic acid, furnishes a certain degree of heat and energy, inasmuch as all the acetic acid is burned in the body, the products being water and carbon dioxide. Salt enters not into the tissues of the body but affords hydrochloric acid, which is essential to digestion. On the other hand, wood smoke, a valuable condiment, does not have any food value.

Manner in Which Food Performs Its Functions. All food products ingested in the alimentary canal, if not already in a condition suitable for digestion, are prepared by previous mastication. The importance of the mastication of the food is shown by two facts: (1) the food in order to be digested must be properly subdivided; (2) the mixing of saliva with starchy foods is an important adjunct to digestion. In so far as meat foods are concerned, the admixture of saliva is perhaps of no importance in digestion, and the need of complete mastication is not so evident.

The chief functions of food have been noted in the original definition. All foods taken into the body, with the possible exception of water and wood smoke, undergo profound modifications. The process of digestion is essentially a chemical one, and consists in the thorough destruction of the ingested forms of matter and the building up of entirely new combinations. Attention may be called, for instance, to the fact that the fat of the human body does not consist of any particles of the fat ingested in the food, but is a substance which is generated by combinations of particles of matter in the processes of digestion and assimilation. The tissues of the body, under a selective influence which is not fully understood, cull out from the current of circulating blood those particular particles of matter which go to build them up and reject those which are of no use.

Metabolism. The building of tissue, especially in the growing animal, is one of the chief functions of foods. When an animal has reached maturity it remains in practically the same condition for a number of years. In this condition the building of new tissues ceases and nature is satisfied with restoring those which are destroyed and excreted. This process of repairing waste keeps the adult body in a state of equilibrium for a given time, but as old age comes on the repair does not keep pace with the waste and the natural decadence of age ensues. The sum of changes which food undergoes from its entry into the body until excreta are voided is *metabolism.*

Basal Metabolism. In recent years since the great advance in the knowledge of nutrition has been made, increased importance has been given to bromato therapy. It is important to know what the normal metabolism of a person is when he is resting at perfect ease, in order to know how much nutrient he requires. Numerous apparatus intended particularly for use at the bedside have been devised for this purpose. The food materials used in the human system in the normal movements and processes of the body are called basal metabolism.

Foods as Fuel. The most important function of the food is to furnish heat and energy. The human body is a pure machine and its functions depend upon a supply of heat and energy just as much as a boiler or an engine. Foods furnish heat in varying quantities as already indicated. Starch and sugar furnish about 4,000 units of heat per unit of weight; protein matter, if completely burned, furnishes about 5,500 units of heat per unit of weight; fats, when completely burned, furnish about 9,300 units of heat per unit of weight. In point of fact, however, protein matter is not completely burned in the body, and a considerable amount of nitrogen is excreted without being reduced to the last state of oxidation. Hence, protein matter does not furnish any more heat during the process of digestion and assimilation than an equal amount of carbohydrates, so that the heat value of a protein, in so far as the human machine is concerned, is practically the same as that of a sugar or a starch, while the value of a particle of fat is two and a quarter times greater than that of either a protein or a carbohydrate.

The Calorimeter. A simple method of calculation is pursued in measuring heat value. A particle of food is inclosed in a strong steel vessel, called a *bomb,* and into this vessel oxygen is pumped under high pressure. The apparatus is so arranged that by means of platinum wire, or other appropriate device, the food substance may be ignited in the atmosphere of oxygen and burned completely into final forms of oxidation, producing water, carbon dioxide, nitric, phosphoric and sulphuric acids, according to the relative quantities of the various constituents present. Before igniting the particle of food, the whole apparatus is set in a measured quantity of water at a known temperature and the rise of temperature attained is carefully noted by a standard thermometer. This apparatus is called a *calorimeter.* In this manner the accurate data which are used have been obtained.

The Body a Furnace. An exactly similar process goes on in the human organism, though slowly, and experiments have shown that the data obtained by the calorimeter are entirely comparable with those obtained in the organism. This has been proved by inclosing a human being in a tight compartment by means of which all the heat and all the products of combustion which are produced in his organism are measured. This experiment shows how complete a machine the human organism is.

Average Distribution of the Dry Food. Assuming that the average man eats one and a half pounds of dry food per day, experience has shown that this is distributed in about the following proportions:

Protein	0.25 lb.
Fat	0.20 lb.
Carbohydrates	1.00 lb.
Mineral matter, etc.	0.05 lb.

The above data are to be considered only as approximate expressions of the general distribution of the diet of an ordinary person.

Adulteration of Food. Adulteration of food has been largely practiced for the purpose of commercial gain. In so far as nutrition and palatability are concerned, and from the common point of view of the consumer, there is no possible excuse for adulteration of any kind. The sole purpose of the practice of adulteration is to secure unearned profit for the manufacturer and dealer. Adulteration of food is practiced in various ways, the most common of which are as follows:

(a) *The abstraction of some valuable ingredient.* This is illustrated in the skimming of milk and the sale of the product as whole milk.

(b) *The addition of some agent which dilutes or weakens the product.* This is shown in the addition of water to milk; of chicory to coffee; of ground shells to pepper and other spices, and in many other ways.

(c) *The concealing of inferiority of a product.* This is done chiefly by coloring or bleaching, as for instance, the use of color in a distilled vinegar to make it appear like cider vinegar; the addition of an artificial flavor to an extract to make it resemble the genuine article; the bleaching of flour to make it look like high-grade patent flour.

(d) *The addition of a substance to a food product which may render it injurious to health.* This is practiced chiefly for the purpose of preserving foods, though some of the coloring matters employed are undoubtedly injurious to health, such as sulphate of copper and many coal tar dyes. Many authorities on hygiene are of the opinion that any kind of a preservative drug added to a food product is injurious. The reason for this belief is that a preservative only acts by destroying or paralyzing germ life and a preservative is only effective when enough of it is added to secure this effect. It is a very common opinion among experts, especially those charged with the protection of the public health, that all such practices are objectionable. On the other hand, there are experts, also eminent in their professions, who maintain that the use of preservatives is not deleterious. All nations that have food laws have either forbidden or restricted the use of these preservative materials, and this shows that the feeling of the community is decidedly opposed to them. When it is further considered that every kind of food which is suitable for human consumption may be perfectly preserved in some unobjectionable way without the use of preservatives, it is evident that their employment is wholly unnecessary and, therefore, always objectionable.

Misbranding Food Products. Almost as objectionable as adulteration is the practice of misbranding. As in the case of adulteration, this is done solely to secure undeserved profits on the part of the manufacturer or dealer. From the consumer's point of view there can be no excuse offered for the misbranding of foods. This misbranding takes various forms of which the following are some examples:

(a) *Misbranding* as to the state or country in which the food is produced, as, for instance, representing a domestic oil as of foreign manufacture, either by name or other device.

(b) *The giving of a false or fictitious name of the manufacturer.* This is a very common practice among those who make different grades of products. Their own names are placed on the high grades and the names of fictitious firms on the low grades.

(c) *The calling of adulterated food by the name of the real article.* This is probably the most common form of misbranding, and is illustrated in the sale of milk which has been skimmed and watered as milk; a buckwheat flour which has been mixed with other materials as buckwheat flour, and maple sirup mixed with other sweets as maple sirup.

(d) *The misrepresentation of the qualities of a food product is another form of misbranding.* It is not uncommon to see advertisements calling attention to "superior qualities" which the article does not possess, such as "the most wholesome," "best made," "entire substitute for," and similar terms. A most dangerous practice, and one which threatens health and often life, is found in the claims made for certain varieties of infants' and invalids' food. Another very common form of misbranding is where long stored foods are advertised as fresh—a form of misbranding which is now receiving attention in all the countries of the world, and regulations are being made looking to the minimizing of this evil. Infants' and invalids' foods of all others, should be pure, wholesome and free from misbranding and adulteration.

CHEMICAL ELEMENTS

Tabulation of facts concerning all the known elements.

At. wt., atomic weight; At. no., atomic number; S. G., specific gravity; M. P., melting point; B. P., boiling point; C. T., critical temperature; ca., about.

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Actinium Symbol Ac. At. wt. undetermined. At. no., 89.	Occ. In all uranium minerals, and nowhere else, associated mainly with lanthanum. Prep. The metal has not been isolated.	A radioactive element, with a half-period of 20 years.	In chemical properties, it is intermediate between calcium and lanthanum.
Aluminium Symbol Al. At. wt. 26.97. At. no. 13. Valence III. S. G. 2.6. M. P. 658°.	Occ. Cryolite AlF_3, 3NaF; bauxite, impure $Al(OH)_3$; in feldspars, micas and clay; emery, ruby, sapphire (Al_2O_3). Prep. Com'l, by electrolysis of Al_2O_3, from bauxite, dissolved in cryolite, water-power usually furnishing the electrical energy.	Silver-white, ductile, malleable at 120°, tensile strength (wrought) 16 tons per sq. in. A better conductor of electricity, weight for weight, than copper. Molten metal not mobile enough to make castings. It turns badly in the lathe. Acted upon by dil. hydrochloric acid, slowly by sulphuric, but not by nitric or the acids occurring in foods. Soluble in alkaline hydroxides. The tarnishing action of moist air soon comes to an end as the tarnish acts as an adherent protective coating.	Used for cooking utensils, boat-building, military accouterments and small articles requiring lightness and strength; for electric leads. The powdered metal is used as a body for paint; and its mixture with ferric oxide, called thermite, is used for producing very high temperatures (up to 3700°C.) for welding rails, etc. Many metals are reduced from their oxides by means of Al, hence its use in casting steel. Aluminum bronze (10% Al), rolled, has tensile strength of 40 tons per sq. in. Its sulphate forms alums, *e.g.*, $KAl(SO_4)_2$, $12H_2O$, common alum.
Antimony Symbol Sb. At. wt. 121.77. At. no. 51. Valence III and V. S. G. 6.7. M. P. 630.7°. B. P. red heat.	Occ. Free, and as stibnite (Sb_2S_3). Prep. Roasting stibnite gives Sb_2O_4, which is then reduced by heating with carbon.	White, brittle, crystalline metal. Its alloys expand on solidification, and therefore give very sharp castings, *e.g.*, for type. It does not tarnish, but may be burned in air, and unites directly with the halogens.	The metal is a constituent of the alloys type metal, Britannia metal and Babbitt metal (used for bearings). Its oxide (Sb_2O_3) is both basic and acidic. The trichloride, butter of antimony ($SbCl_3$), is easily hydrolyzed. Tartar emetic ($SbOKC_4H_4O_6$) is used in medicine and in dyeing.
Argon Symbol A. At. wt. 39.91. At. no. 18. Valence nil. Density 39.9 (oxygen =32). B. P. −186°. M P. −190°.	Present in the air 0.94% by volume. To isolate, air is freed from CO_2 by soda-lime, water by P_2O_5, oxygen by red-hot copper, nitrogen by magnesium and calcium. From the residual mixture argon is obtained by fractional distillation.	Is a monatomic gas and is identified by its characteristic spectrum seen by examining the light emitted when the gas is placed in a vacuum tube at low pressure and sparked. More soluble in water than nitrogen, 100 vols. water dissolving 4 vols. argon under ordinary conditions.	Forms no compounds, hence its name—meaning "inactive."
Arsenic Symbol As. At. wt. 74.96. At. no. 33. Valence III and V. S. G. 5.7. B. P. 450° (sublimes). M. P. 480° (under pressure).	Occ. Free, as arsenical pyrites (FeSAs), as orpiment (As_2S_3) and as realgar (As_2S_2). Prep. By heating arsenical pyrites, $FeSAs \longrightarrow FeS + As$.	A steel-gray, dully-metallic and crystalline element classed as a metalloid because intermediate between metals and nonmetals. Its vapor has a density corresponding to As_4 at 644°, and to As_2 at 1700°. It burns in air and unites directly with the halogens, sulphur and with many metals.	Used for hardening lead for shot. All its compounds are poisonous. White arsenic (As_2O_3) is partly basic, forming a chloride and partly acidic, forming arsenites. Scheele's green ($CuHAsO_3$) is a pigment dangerous in wallpapers. Traces of arsenic are detected by Marsh's test, in which the intensely poisonous arsine (AsH_3) is formed.
Barium Symbol Ba. At. wt. 137.37. At. no. 56. Valence II. S. G. 3.6. M. P. red heat.	Occ. As barytes or heavy-spar ($BaSO_4$), and as witherite ($BaCO_3$). Prep. By electrolysis of the fused chloride.	A silver-white, lustrous, malleable metal harder than lead. Like calcium, it acts slowly on water to give barium hydroxide and hydrogen. The vapors of its compounds impart a green color to the Bunsen flame.	The peroxide (BaO_2) was used in the manufacture of oxygen and of hydrogen peroxide. The nitrate and chlorate in pyrotechny to give green fires. The sulphate as the body for a permanent white paint and for filling glazed paper. All soluble compounds are poisonous.
Bismuth Symbol Bi. At. wt. 209. At. no. 83. Valence III (and V). S. G. 9.9. M. P. 266.5°. B. P. ca. 1200°.	Occ. Free and as trioxide (Bi_2O_3) and trisulphide (Bi_2S_3). Prep. The ore is roasted and then heated with charcoal and metallic iron (to remove traces of sulphur).	An exceedingly brittle, crystalline shining metal, white with a tinge of pink. Bismuth expands on solidification. It does not tarnish, but can be burnt in air. Dissolves in oxygen acids.	Used for making fusible alloys, *e.g.*, Wood's metal, M.P. 60.5°, which are used in plugs of fire sprinklers and boiler safety valves, and for taking casts. The oxynitrate is used in medicine and as a cosmetic.
Boron Symbol B. At. wt. 10.82. At. no. 5. Valence III. S. G. (amorph.) 2.4; (cryst.) 2.5. B. P. 3500° (sublimes).	Occ. As boric acid (H_3BO_3), borax ($Na_2B_4O_7,10H_2O$), colemanite ($Ca_2B_6O_{11},5H_2O$). Prep. Amorphous boron by reducing B_2O_3 with Mg. Impure cryst. boron by reducing B_2O_3 with excess of Al.	Amorphous boron is a greenish black powder that burns in air at 700°, forming B_2O_3 and also BN. It is oxidized, by hot conc. sulphuric or nitric acids, to boric acid.	The compounds are analogous to those of silicon. Borax is used as a flux, and, in solution, as a mild alkali on account of its hydrolysis. Boric acid is used as a weak antiseptic and preservative.
Bromine Symbol Br. At. wt. 79.916. At. no. 35. Valence I. S. G. 3.2. B. P. 59°. M. P. −7.3°.	Occ. In seawater as alkali bromide, and in the upper layers of salt deposits as sodium and magnesium bromide. Prep. By treatment of the brines with sulphuric acid and manganese dioxide, or else with chlorine.	A dark red liquid, smelling like chlorine, whose vapor irritates eyes, throat and nose. Dissolves in thirty parts of water (bromine water). Combines directly with most other elements, but less vigorously than chlorine.	Potassium bromide is used in medicine; silver bromide in photography. Bromine is used in course of the preparation of organic dyes.
Cadmium Symbol Cd. At. wt. 112.41. At. no. 48. Valence II. S. G. 8.6. M. P. 321.7. B. P. 770°.	Occ. In association with the zinc ores, as carbonate and sulphide. Prep. In the distillation of impure zinc, the cadmium comes over in the first portions.	A silver-white metal, more ductile and malleable than zinc. It burns in air, and is attacked by dilute acids.	All the compounds are poisonous, and little ionized. The suphide (CdS) is the basis of "cadmium yellow." The iodide is used in medicine. The metal is used as a protective plating.
Caesium Symbol Cs. At. wt. 132.81. At. no. 55. Valence I. S. G. 2.4. M. P. 26.3°. B. P. 670°.	Occ. In certain micas, and in the ashes of certain plants. Prep. By heating the hydroxide (CsOH) with magnesium.	A white silvery metal resembling potassium. It is one of the most active of metals, and decomposes water violently.	The compounds are characterized by giving, especially, two bright lines in the blue of the spectrum (*caesius*, sky-blue).
Calcium Symbol Ca. At. wt. 40.07. At. no. 20. Valence II. S. G. 1.54. M. P. 760°.	Occ. As carbonate (Iceland spar, calcite, aragonite, marble, chalk, limestone), sulphate (gypsum), phosphate (apatite), fluoride (fluor spar), and as complex silicates in great variety (feldspars, pyroxenes, amphiboles, etc.). Prep. By electrolysis of the fused chloride.	A white crystalline metal, harder than lead, that can be cut, drawn, rolled and turned. It attacks water, and burns in the air at a red heat, forming the oxide (CaO) and the nitride (Ca_3N_2). It unites with hydrogen to CaH_2, whose action on water is a source of hydrogen for balloons.	Calcium oxide (quicklime) is used for mortar and to remove hair from hides. The hydroxide [$Ca(OH)_2$] mixed with sand forms mortar; its solution is limewater. Plaster of Paris, a less hydrated sulphate, takes up water on setting to form $CaSO_4,2H_2O$. The phosphates are fertilizers. Bleaching powder is CaClOCl and calcium carbide is CaC_2. Common glass contains silicates of calcium and sodium.

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Carbon Symbol C. At. wt. 12.00. At. no. 12. Valence IV. S. G. diamond 3.5; graphite 2.3; amorphous 1.9. M. P.—not realized.	Occ. As diamond and graphite, in the free state; in combination with hydrogen as petroleum, with oxygen as carbon dioxide in the air, with these and other elements as coal, and in plant and animal tissues; and as many carbonates. Prep. By dry distillation of wood or coal, yielding charcoal and coke respectively.	Diamond is crystalline and the hardest of minerals, the dark-colored "bort" being used for cutting and grinding. Graphite has a black metallic luster, is crystalline and may be scratched by the finger-nail. Charcoal is amorphous, and possesses the power of absorbing gases and also coloring matters. All three forms burn in oxygen to produce carbon dioxide.	The carbon compounds form the subject of "organic chemistry." Carbon dioxide results from the burning of coal, coke, wood, oil or illuminating gas, from fermentation and decay, which are slow burnings, and is exhaled in the breath. Carbon monoxide, arising from recently-stoked fires, is an exceedingly poisonous gas.
Celtium (Hafnium) Symbol Ct. (Hf.). At. wt. 178.6. At. no. 72. S. G. 12.1.	Occ. Associated with zirconium. Prep. By decomposing the tetraiodide.	Analogous to zirconium.	Similar to zirconium compounds, from which it is separated by fractional crystallization of double fluorides.
Cerium Symbol Ce. At. wt. 140.25. At. no. 58. Valence III, IV (and VI). S. G. 7.0. M. P. 623°.	Occ. As silicate in cerite, along with Nd, Pr and La; also in monazite sand. Prep. By electrolysis of the fused chloride.	A metal with the color and luster of iron, like tin in hardness, and very ductile and malleable. Burns in air more easily and brightly than magnesium.	Welsbach incandescent gas mantles contain one per cent of cerium dioxide CeO_2.
Chlorine Symbol Cl. At. wt. 35.57. At. no. 17. Valence I (and VII). S. G. (liquid) 1.3. M. P. −102°. B. P. −33.6°. C. T. +146°.	Occ. In seawater as chlorides of the alkalis and alkaline earths, and as like compounds in salt deposits. Prep. By electrolysis of alkali chloride, fused or in solution; or by the action of manganese dioxide on hydrochloric acid.	A greenish-yellow gas of characteristic odor, with a violent action on the respiratory tract. Unites directly with all elements save oxygen, nitrogen and the argon family. Displaces bromine and iodine from bromides and iodides, and substitutes hydrogen in organic compounds.	The gas is used in extracting gold and in preparing bleaching and disinfecting agents. In presence of water it bleaches many coloring matters. Forms chlorides (as NaCl, HCl, $CaCl_2$), hypochlorites [as solution of $Ca(OCl)_2$], chlorates (as $KClO_3$, used for matches and in pyrotechny) and perchlorates (as $KClO_4$).
Chromium Symbol Cr. At. wt. 52.01. At. no. 24. Valence II, III and VI. S. G. 6.9. M. P. 1515°.	Occ. As chromite [$Fe(CrO_2)_2$]. Prep. By reducing Cr_2O_3 with aluminum filings.	A steel-gray, lustrous, brittle and very hard metal. At high temperatures it burns in air to green Cr_2O_3. It is attacked by dilute sulphuric or hydrochloric acid, but not by nitric acid.	The alloy ferrochromium is used in steel-making. Chrome green, the pigment, is Cr_2O_3. Chrome yellow is $PbCrO_4$. Bichromates (as $K_2Cr_2O_7$) are used in photo-processes, tanning and dyeing and as oxidixing agents, *e.g.*, in batteries. The metal is used as a protective plating.
Cobalt Symbol Co. At. wt. 58.94. At. no. 27. Valence II and III. S. G. 8.5. M. P. 1500°.	Occ. As smaltite ($CoAs_2$) and cobaltite (CoAsS). Prep. By igniting the oxide in hydrogen.	A white magnetic malleable metal, less tenacious than iron. By exposure it turns pinkish. It is less active chemically than iron.	Its intensely blue silicates are used in coloring porcelain and constitute the pigment smalt.
Columbium (Niobium) Symbol Cb. At wt. 93.1. At. no. 41. Valence I, II, IV and V. S. G. 12.7. M. P. 1950°.	Occ. In the mineral columbite. Prep. By reduction of CbO_2 by paraffin.	A light-gray malleable and ductile metal, as hard as wrought iron, which is not affected by acids, even by aqua regia.	The hydfide (CbH) burns in air. The compounds occur with those of tantalum, which they closely resemble.
Copper Symbol Cu. At. wt. 63.57. At. no. 29. Valence I and II. S. G. 8.9. M. P. 1084.1. B. P. 2100°.	Occ. Free, as cuprite (Cu_2O), copper glance (Cu_2S), chalcopyrite (Cu_2S, Fe_2S_3), malachite [$CuCO_3,Cu(OH)_2$]. Prep. After removal of iron and sulphur, the oxide is reduced by heating with carbon. It is refined electrolytically.	A red, lustrous, very ductile and malleable metal of tensile strength 14 tons per sq. in., second only to silver in electrical conductivity. In ordinary air it gradually becomes coated with basic carbonate. In absence of air, nitric acid alone among the dilute acids attacks it, but in presence of air even the acids found in foodstuffs can dissolve it.	The metal is used for coins, electroplating, electric leads, roofing, cooking vessels and for making alloys, such as brass, bell and gun metals, German silver and the bronzes. The soluble compounds are poisonous, and are therefore used as germicides in agriculture. Blue vitriol is $CuSO_4,5H_2O$; the basic acetate is verdigris.
Dysprosium Symbol Dy. At. wt. 162.52. At. no. 66. Valence III.	Occ. In monazite, gadolinite, etc. Prep. Not yet isolated.	The oxide dysprosia, along with three other rare earths, constitutes crude erbia.	The salts are green or yellow in color and show characteristic absorption bands.
Erbium Symbol Er. At. wt. 167.7. At. no. 68. Valence III.	Occ. Same as for dysprosium. Prep. Not yet isolated pure.	Crude erbia has been separated into erbia (oxide of erbium), holmia, thulia and dysprosia.	The salts are rose-colored, and show characteristic absorption spectra.
Europium Symbol Eu. At. wt. 152.0. At. no. 63. Valence III.	Occ. In monazite and other rare minerals. Prep. Not yet isolated.	This element so closely resembled samarium that the analytical separation of the two is difficult.	The salts are pinkish and show a faint absorption spectrum.
Fluorine Symbol F. At. wt. 19.0. At. no. 9. Valence I. S. G. (liquid) 1.14 at −187°. M. P. −223°. B. P. −187°.	Occ. As cryolite ($AlF_3,3NaF$), fluor spar (CaF_2) and very widely elsewhere in small quantities. Prep. By electrolysis of dry hydrogen fluoride at −23°.	A pale yellowish-green gas that unites with every element excepting oxygen and the argon family. It rapidly displaces oxygen from water or chlorine from hydrogen chloride.	Hydrogen fluoride is used for etching glass and in silicate analysis. Silver fluoride is soluble and calcium fluoride insoluble, in contrast with the other halides of these metals.
Gadolinium Symbol Gd. At. wt. 157.26. At. no. 64. Valence III.	Occ. In gadolinite and samarskite. Prep. Not yet isolated.	This element closely resembles terbium in its compounds.	The salts are colorless and show no absorption bands.
Gallium Symbol Ga. At. wt. 69.72. At. no. 31. Valence III. S. G. 5.9. M. P. 30.1°.	Occ. In zinc blende and in bauxite. Prep. By electrolysis of a suitable solution of its salts.	A bluish-white tough metal that may be cut with a knife. Like aluminium, it is soluble in hydrochloric acid and in caustic alkali, but not in nitric acid.	It forms two chlorides ($GaCl_3$ and $GaCl_2$) which yield spark spectra very characteristic of gallium.
Germanium Symbol Ge. At. wt. 72.60. At. no. 32. Valence II and IV. S. G. 5.5. M. P. 900°.	Occ. In the rare mineral argyrodite. Prep. By the reduction of the dioxide (GeO_2) by carbon.	A grayish-white brittle, lustrous metal, insoluble in hydrochloric acid. It combines directly with the halogens.	The close relation of this element to carbon and silicon is shown in the compound germanium chloroform ($GeHCl_3$).

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Glucinum (or Beryllium) Symbol Gl. At. wt. 9.02.—At. no. 4. Valence II.—S. G. 1.8. M. P. below 960°.	Occ. In beryl [$Al_2Gl_2(SiO_3)_6$]. Prep. By electrolysis of the fused double fluoride $GlF_2,2KF$.	A hard white metal that tarnishes when heated in air, and is soluble in dilute acids when powdered.	Its hydroxide [$Gl(OH)_2$] is feebly acidic as well as basic, thus resembling the hydroxide of zinc. Emerald is beryl colored green by chromium.
Gold Symbol Au. At. wt. 197.2. At. no. 79. Valence I and III. S. G. 19.32. M. P. 1062.4°.	Occ. Chiefly free, but also as telluride; many specimens of iron pyrites are auriferous. Prep. From gold-bearing sands by washing away the lighter material, and dissolving the gold from the residue by mercury, which is subsequently separated from the gold by distillation. Quartz ores are pulverized in stamping mills, and the powder is then carried by water over amalgamated copper plates on which the gold collects.	A soft bright-yellow metal, easily scratched by the knife, an excellent conductor of heat and of electricity. The most ductile and the most malleable of all the metals. Chemically, gold is rather inert, and is not attacked by the oxygen of the air, by hydrogen sulphide, nor, indeed, by any single one of the common acids. It is attacked by fused alkalis, yielding aurates, and by aqua regia, yielding chlorauric acid ($HAuCl_4$).	Pure gold is called 24-carat gold. American, French and German gold coins are 21.6 carat, while British sovereigns are 22 carat, the balance in all these cases being copper. Jewelry is made in 18, 14, 9, etc., carat gold, the addition of copper increasing the hardness and rigidity. Sodium chloraurate ($NaAuCl_4$) is used for "toning" in photography, while potassium auricyanide [$KAu(CN)_4$] is used in electrogilding.
Helium Symbol He. At. wt. 4.00. At. no. 2. Valence 0. S. G. (liquid) 0.15. B. P. −268.7°.	Occ. In air to the extent of 1 to 2 volumes per million; also occluded in certain minerals. Prep. Neon and helium are boiled off crude argon, and the neon solidified by cooling.	The lightest gas after hydrogen, transparent, odorless and colorless, very inert, forming no compounds with other elements.	It is one of the decomposition products of certain other (radio-active) elements.
Holmium Symbol Ho. At. wt. 163.5. At. no. 67.	A rare earth metal, which occurs with and is separated from the erbium subgroup of the rare earths.	The metal has not been isolated.	The salts are yellow, and are similar to those of dysprosium.
Hydrogen Symbol H. At. wt. 1.008. At. no. 1. Valence I. S. G. (liquid) 0.07. M. P. −259°. B. P. −252.5°.	Occ. In air to the extent of 1 vol. per 20,000 vols. air; combined, in water (11.19% by wt.) natural gas, petroleum and all animal and vegetable bodies. Prep. By treating zinc with hydrochloric or sulphuric acid; by electrolysis of water.	The lightest gas, transparent, odorless and colorless, soluble in water (2 vols. in 100 vols. water under everyday conditions), in platinum, in palladium (502 vols. in 1 of Pd). Burns in air and in chlorine and unites with many of the other elements.	Its two oxides are water (H_2O) and hydrogen peroxide (H_2O_2), the latter of which is used in solution as a bleaching agent. Every acid contains hydrogen as an essential constituent. Its compounds with carbon and other elements number over 100,000. Hydrogen gas is used for the oxyhydrogen flame and for filling balloons.
Illinium Symbol Il. At. wt. undetermined. At. no. 61.	Occ. With the cerium earths, from which its salts are separated.	The metal has not been isolated, but is recognized by its X-ray spectrum, and by its optical absorption spectrum.	The compounds are similar to those of neodymium and samarium.
Indium Symbol In. At. wt. 114.8. At. no. 49. Valence III and I. S. G. 7.4. M. P. 176°.	Occ. In zinc blende (ZnS). Prep. Electrolytically from solutions of its salts.	A white metal, malleable and softer than lead.	Its compounds color the nonluminous gas flame blue and show a characteristic blue line in the spectrum.
Iodine Symbol I. At. wt. 126.932. At. no. 53. Valence I, V and VII. S. G. 4.95. M. P. 114°. B. P. 184°.	Occ. In the ocean, in certain seaweeds, and in Chili saltpeter, always in the combined state. Prep. From iodides by displacement of their iodine by chlorine.	A dark gray brittle solid with a metallic luster. Its vapor is violet, as are its solutions in chloroform and in carbon bisulphide. It requires over 5,000 parts of water for its solution. Combines directly with many elements, but is much less active than chlorine and bromine.	Its tincture is used in medicine as a counter-irritant. Potassium iodide (KI) and iodoform (CHI_3) likewise find application in medicine. The alkyl iodides (*e. g.* C_2H_5I) are much used in synthetic organic chemistry.
Iridium Symbol Ir. At. wt. 193.1. At. no. 77. Valence III and IV. S. G. 22.42. M. P. 1950°.	Occ. Along with platinum. Prep. By a complex series of operations from platinum ores.	A white metal, brittle when cold, and very hard. It is attacked by fused alkalis, but not by aqua regia.	It is used for pointing gold pens. Its alloy with 9 parts of platinum is used for standard meter bars on account of its inalterability.
Iron Symbol Fe. At. wt. 55.84. At. no. 26. Valence II and III. S. G. 7.86; pig, 7.03 to 7.73. M. P. 1804°. wrought 1600°. steel 1375°. gray pig 1275°. white pig 1075°.	Occ. As magnetic oxide (Fe_3O_4), hematite (Fe_2O_3), limonite ($2Fe_2O_3,3H_2O$), siderite ($FeCO_3$), which are important ores; iron pyrites (FeS_2); in rocks as complex silicates, and in plants and animals. Prep. Pig iron is prepared in the blast furnace by reduction of the ore by means of carbon monoxide in presence of a suitable flux. From pig iron, wrought iron is obtained by puddling, and steel by the Bessemer, open-hearth or other process.	A white, malleable, ductile, magnetic metal, unchanged in dry air or air-free water, but rusting in moist air. Easily attacked by dilute acids, but not by fused alkalis. Cast iron contains 2 to 5% of carbon and other impurities, and is hard and brittle. Wrought iron contains less than 0.2% of carbon, and is softer and tougher, with a tensile strength of 22 to 25 tons per sq. in. Steel contains from 0.2 to 1.5% of carbon, is permanently magnetic, may be tempered, and possesses tensile strength up to 100 tons per sq. in.	The metal is used as a structural material, for rails, machinery, tools, etc. Jeweler's rouge and Venetian red consist of the oxide (Fe_2O_3). Rust is chiefly the hydrated oxide (FeO,OH). Hammer scale and lodestone have the composition Fe_3O_4. Ferric chloride ($FeCl_3$), ferrous iodide (FeI_2) and other iron compounds are used in medicine. Green vitriol ($FeSO_4,7H_2O$) is used in making ink, and in dyeing. Potassium ferrocyanide [$K_4Fe(CN)_6$] is used for making Prussian blue, potassium cyanide, etc.
Krypton Symbol Kr. At. wt. 82.9. At. no. 36. Valence 0. M. P. −169°. B. P. −152°.	Occ. In minute quantity in the air. Prep. From crude argon by fractional distillation.	An inert, colorless, odorless gas, resembling, but denser than, argon.	It forms no compounds, and is identified by its characteristic spectrum.
Lanthanum Symbol La. At. wt. 138.9. At. no. 57. Valence II and V. S. G. 6.15.	Occ. As lanthanite [$La_2(CO_3)_3,8H_2O$]. Prep. By electrolysis of fused $LaCl_3$.	An iron-gray metal tarnishing in air to steel-blue; malleable and ductile. Attacked slowly even by cold water.	When heated in air it forms oxide (La_2O_3) and nitride (LaN).
Lead Symbol Pb. At. wt. 207.20. At. no. 82. Valence II, IV. S. G. 11.4. M. P. 326°.	Occ. As galena (PbS), and in silver ores. Prep. By calcination of partially roasted galena. Purification is effected by Parkes process.	A soft gray metal, malleable, but of low tensile strength. In presence of air, water acts on lead to produce the hydroxide, which, being slightly soluble, may cause lead poisoning if present in water supplies. When heated in air it is oxidized to litharge (PbO), and, under suitable conditions, to minium (Pb_3O_4).	The metal is used for water pipes, roofs and gutters and storage batteries. For shot it is alloyed with 0.4% of arsenic. Typemetal contains 20% of antimony. Babbitt metal, for bearings, contains over 70% of lead. Solder and pewter are alloys of lead and tin. The basic carbonate [$Pb(OH)_2,2PbCO_3$], "white lead," is the basis of most oil paints.
Lithium Symbol Li. At. wt. 6.94. At. no. 3. Valence I. S. G. 0.53. M. P. 186°. B. P. above 1400°.	Occ. As a mixed fluoride with aluminium in amblygonite. Prep. By electrolysis of the fused chloride.	A silver-white metal, softer than lead, that tarnishes quickly in air, and is easily acted upon by water. When heated, it unites vigorously with nitrogen.	The carbonate [$Li_2(CO_3)$] is used in medicine as a solvent for uric acid, lithium urate being soluble. The lithium salts give a carmine flame coloration.
Lutecium Symbol Lu. At. wt. 175.0. At. no. 71.	Occ. In euxenite. Prep. It has not been isolated.		Its compounds resemble those of ytterbium.

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Magnesium Symbol Mg. At. wt. 24.32. At. no. 12. Valence II. S. G. 1.75. M. P. 633°. B. P. 1100°.	Occ. As magnesite ($MgCO_3$), dolomite ($MgCO_3$,$CaCO_3$), carnallite ($MgCl_2$,KCl, $6H_2O$) and in very many complex silicates. Prep. By electrolysis of dried, fused carnallite.	A silver-white metal, ductile when hot. It tarnishes in air, and acts slowly upon water, rapidly on steam. Burns in air to the oxide MgO, emitting a very bright light used in photography. It units directly with nitrogen.	The sulphate ($MgSO_4$,$7H_2O$) is known as epsom salts and is used in medicine, as are the oxide (magnesia), the carbonates and citrate. Magnalium is a light, hard alloy with aluminium.
Manganese Symbol Mn. At. wt. 54.93. At. no. 25. Valence II, III, IV, VI, VII. S. G. 8.0. M. P. ca. 1300°.	Occ. As pyrolusite (MnO_2), beaunite (Mn_2O_3), hausmannite (Mn_3O_4) and manganese spar ($MnCO_3$). Prep. By heating Mn_3O_4 with aluminium filings.	A steel-gray, hard, brittle metal with a pinkish tinge. It rusts in moist air and is attacked by dilute acids.	Ferromanganese and spiegeleisen are alloys with iron, used in steel making. With copper it forms the hard, tough manganese bronzes, with tensile strength up to 30 tons per sq. in. Impure sodium permanganate ($NaMnO_4$) is used in disinfecting as Condy's fluid.
Masurium Symbol Ma. At. wt. undetermined. At. no. 43.	Occ. In platinum ores and in columbite.	The metal has not been isolated, but is recognized by its X-ray spectrum.	The compounds have not been studied.
Mercury Symbol Hg. At. wt. 200.61. At. no. 80. Valence I and II. S. G. 13.6. M. P. −39.5°. B. P. 356.95°.	Occ. Free and as cinnibar (HgS). Prep. By roasting cinnibar $HgS+O_2$——$Hg+SO_2$.	A silver-white mobile liquid with a vapor pressure at 0° of 0.0002 mm. It tarnishes but slowly in air and is attacked only by dilute nitric among the dilute acids. The vapor is monatomic.	It is used for filling thermometers and barometers. Its alloys are called amalgams, some of which are used in dentistry. Calomel (HgCl) is administered internally in medicine; corrosive sublimate ($HgCl_2$) forms a solution with very powerful germicidal properties.
Molybdenum Symbol Mo. At. wt. 96.0. At. no. 42. Valence III, IV, V, VI. S. G. 9.0. M. P. 2110°.	Occ. As molybdenite (MoS_2) and wulfenite ($PbMoO_4$). Prep. By reducing the oxides with aluminium powder.	A white metal, as malleable as iron, that will not scratch glass. Insoluble in hydrochloric or dilute sulphuric acid.	The ferromolybdenum alloys are used in the manufacture of special steels.
Neodymium Symbol Nd. At. wt. 144.27. At. no. 60. Valence III and IV. S. G. 6.9. M. P. 840°.	Occ. With cerium and lanthanum. Prep. By electrolysis of the fused chloride.	A yellowish metal, tarnishing in air.	The salts are rose-violet in color, and their solutions show characteristic absorption spectra.
Neon Symbol Ne. At. wt. 20.2. At. no. 10. Valence 0. B. P. ca. −243°.	Occ. In minute quantity in the atmosphere. Prep. Neon and helium are boiled out of crude argon, and the neon separated from helium by cooling with liquid hydrogen.	A colorless, transparent, odorless, inert gas, resembling argon.	It forms no compounds, and is recognized by its characteristic spectrum.
Nickel Symbol Ni. At. wt. 58.69. At. no. 28. Valence II and III. S. G. 8.9. M. P. ca. 1485°.	Occ. As nicollite (NiAs) and nickel glance (NiAsS). Prep. By igniting the oxalate in hydrogen.	A white, very hard, lustrous metal, malleable, ductile and tenacious. It rusts but slowly in air, and is attacked easily by only nitric acid.	The metal furnishes a protective coating when plated on iron. German silver is an alloy of nickel, copper and zinc. Nickel steel is used for armor plates. Manganin, containing nickel, copper and manganese, is used for electrical resistances.
Niton Symbol Nt. At. wt. (see under properties) At. no. 86. Valence 0.	Occ. As a gaseous product of the disintegration of atoms of Ra, ThX or AcX, all of which are isotopic forms of element 88. Prep. In the form of radon, admixed with air, by passing air through solutions of radium salts.	Element 86 is represented by three isotopes, radon (Rn, at. wt. 222), thoron (Tn, at. wt. 220) and actinon (An, at. wt. ?) all of which are inert gases of the helium family and indistinguishable by purely chemical methods. Each is radioactive, emitting alpha rays, and the half-periods are 3.85 days, 54 seconds and 3.9 seconds respectively.	They form no compounds. Radon is used in the treatment of cancer, enclosed in minute glass vessels of the size of a small matchhead, which is inserted into the tumor.
Nitrogen Symbol N. At. wt. 14.008. At. no. 7. Valence III and V. M. P. −214°. B. P. −194°.	Occ. Free nitrogen forms about four-fifths of air by volume. As Bengal saltpeter (KNO_3), Chili saltpeter ($NaNO_3$); and as an essential constituent of vegetable and animal protoplasm. Prep. By heating ammonium nitrite, by oxidation of ammonia, etc.	A colorless, odorless, transparent gas, rather inactive chemically. At ordinary temperature and pressure, 100 volumes of water dissolve 1.5 volumes of nitrogen. It unites directly with strongly heated boron, lithium, calcium and magnesium.	Nitrous oxide (N_2O), or laughing gas, is used by dentists. Nitric acid (HNO_3) has many applications in technical chemistry. Ammonia (NH_3) is a very soluble gas. Ammonium sulphate [$(NH_4)_2SO_4$] and Chili saltpeter are used as nitrogenous manures. Nitrogen is a constituent of the aniline dyes, the proteins and many other important classes of organic substances.
Osmium Symbol Os. At. wt. 190.8. At. no. 76. Valence II, III, IV, VI, VIII. S. G. 22.477. M. P. ca. 2400°.	Occ. Along with platinum. Prep. By reducing OsO_4.	A gray metal, harder than glass, the heaviest of known bodies.	Its alloy with iridium is used in tipping gold pens. Osmium tetroxide (OsO_4) is used as a microscopic stain for fat.
Oxygen Symbol O. At. wt. 16.00. At. no. 8. Valence II. S. G. (liquid at b.p.) 1.13. M. P. −227°. B. P. −182.5°.	Occ. Free oxygen forms about one-fifth of air by volume. Water contains 88.88% of oxygen. The rocks of the earth's crust contain about 45% in combination, chiefly as silicates. Prep. In the laboratory, by heating potassium chlorate ($KClO_3$). Commercially from the air.	A colorless, odorless, tasteless, transparent gas, slightly heavier than air. At ordinary temperature and pressure, 100 volumes of water dissolve 3 volumes of oxygen. It is very active chemically, combining directly with all but a few of the other elements to form oxides. Sulphur, phosphorus, etc., burn much more vigorously in oxygen than in air. Liquid oxygen is magnetic.	The gas is sold compressed in mild steel cylinders, and is used for the oxyhydrogen blowpipe and in medicine, besides for chemical purposes. It is necessary to support animal respiration and to sustain ordinary combustion. It enters as a constituent into all oxides, most salts and many organic compounds.
Palladium Symbol Pd. At. wt. 106.7. At. no. 46. Valence II and IV. S. G. 11.9. M. P. ca. 1535°.	Occ. Along with platinum, and with gold in Brazil. Prep. By a complex series of processes from platinum ores.	A silvery, malleable and ductile metal, related to platinum, unlike which, however, it is attacked by nitric acid. Under suitable conditions it can take up over 900 volumes of hydrogen.	Since it does not tarnish, it is used for coating silver goods, and by dentists as a substitute for gold.
Phosphorus Symbol P. At. wt. 31.027. At. no. 15. Valence III and V. S. G. white, 1.82. red, 2.25. M. P. white, 44°. B. P. 269°.	Occ. As phosphates, such as apatite [$Ca_5F(PO_4)_3$]; in bones, teeth, brain and seeds of plants. Prep. By reduction of calcium phosphate by carbon in the electric furnace in presence of a suitable flux.	Phosphorus exists in two allotropic modifications: white phosphorus is waxy in consistency, soluble in carbon bisulphide, evil smelling and poisonous; red phosphorus is a solid, insoluble in carbon bisulphide, odorless and not poisonous. White phosphorus has a low ignition temperature, hence its former use in matches.	Red phosphorus is used in the manufacture of matches, as also is the compound P_4S_3. In the form of superphosphate of lime [$CaH_4(PO_4)_2$] phosphorus is an important artificial manure. The chlorides (PCl_3 and PCl_5) are much used in organic chemistry.

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Platinum Symbol Pt. At. wt. 195.23. At. no. 78. Vaience II and IV. S. G. 21.48. M. P. 1753°.	Occ. Free, alloyed with the platinum metals, as nuggets in alluvial sands in the Urals, California, etc. Prep. It is freed from the metals with which it is alloyed by a complex series of processes.	A silvery, tenacious, ductile and malleable metal, unaltered in moist air and unattacked by any single common acid. Aqua regia, fused alkalis, alkali nitrates and cyanides attack it, however. Platinum "sponge" and "black" are finely divided forms.	On account of its resistance to acids, platinum is much used for chemical vessels. Since platinum has a coefficient of expansion very close to that of glass, platinum wires can be fused through glass without danger of breakage on cooling. The salts are used in photography.
Polonium (Radium F) Symbol Po (Ra-F). At. wt. 210. At. no. 84.	Occ. Along with bismuth in uranium minerals. The metal has been isolated only in minute quantity.	A radioactive element, with a half-period 136 days.	The compounds resemble those of tellurium.
Potassium Symbol K. At. wt. 39.096. At. no. 19. Valence I. S. G. 0.86. M. P. 62.5°. B. P. 667°.	Occ. As sylvite (KCl), carnallite (KCl, $MgCl_2,6H_2O$); in plant and animal ashes, and in many complex silicates. Prep. By reduction or by electrolysis of fused potassium hydroxide (KOH).	A silver-white lustrous metal, as soft as wax, tarnishing instantly in moist air. Chemically it is a very active metal, decomposing water in the cold and uniting violently with the halogens, sulphur and oxygen.	An alloy with sodium is used in filling high-temperature thermometers. Bengal saltpeter is the nitrate and is used in pyrotechny, for gunpowder and as a preservative. The iodide (KI) is used in medicine. The chlorate, like the nitrate, is used as a source of oxygen in pyrotechny and for match heads. Caustic potash (KOH) has many chemical applications. The cyanide (KCN) is used in gold extraction.
Praseodymium Symbol Pr. At. wt. 140.92. At. no. 59. Valence III and IV. S. G. 6.47. M. P. 940°.	Occ. With cerium and lanthanum. Prep. By electrolysis of the fused chloride.	A yellowish metal, remaining untarnished in air.	The salts are leek-green in color, and their solutions have characteristic absorption spectra.
Protoactinium Symbol Pa. At. wt. 230? At. no. 91.	Occ. In uranium minerals. The metal has not yet been isolated.	A radioactive element, emitting alpha rays. Its half-period is $1.2x10^4$ years.	The compounds resemble those of tantalum.
Radium Symbol Ra. At. wt. 225.95. At. no. 88. Valence II.	Occ. in minute quantity in pitchblende and other uranium minerals. Prep. The metal has been isolated; the bromide is separated from the barium bromide prepared from pitchblende by fractional crystallization.	In all of its compounds, the metal has the power of emitting certain radiations. These can pass through matter that is opaque to light, render air a conductor, affect a photographic plate and cause a zinc-sulphide screen to fluoresce visibly.	The rays from radium compounds (such as $RaBr_2$, $RaCl_2$, $RaCO_3$) act destructively on living tissues and on bacteria. One gram of radium in any of its compounds, gives off about 100 calories of heat per hour.
Rhenium Symbol Re. At. wt. undetermined. At. no. 75.	Occ. In platinum ores and in columbite.	Its existence is recognized by its X-ray spectrum.	
Rhodium Symbol Rh. At. wt. 102.91. At. no. 45. Valence II, III and IV. S. G. 12.1. M. P. above 2000°.	Occ. In the ores of platinum. Prep. By a complex series of processes from platinum ores.	A silvery, malleable and ductile metal, not tarnishing in air and not attacked by aqua regia.	The red chloride ($RhCl_3$) is formed by the action of chlorine upon the metal.
Rubidium Symbol Rb. At. wt. 85.44. At. no. 37. Valence I, III and V. S. G. 1.52. M. P. 38.5°.—B. P. 696°.	Occ. The salts are associated with salts of potassium. Prep. Similar to that of potassium.	A silver-white metal resembling potassium, like which it attacks water vigorously.	The compounds show characteristic flame-spectra, and were recognized as those of a new element spectroscopically by Bunsen
Ruthenium Symbol Ru. At. wt. 101.7. At. no. 44. Valence III, IV, VI, VII and VIII. S. G. 12.1. M. P. above 2000°.	Occ. In the ores of platinum. Prep. By a complex series of processes from platinum ores.	A hard, white, brittle metal, oxidized when heated in air, scarcely attacked by aqua regia.	The following oxides are known: Ru_2O_3, RuO_2, RuO_4, as well as salts corresponding to RuO_3 and Ru_2O_7.
Samarium Symbol Sa. At. wt. 150.43. At. no. 62. Valence II and III. S. G. ca. 7.7. M. P. 1300 to 1400°.	Occ. In the mineral samarskite. Prep. By electrolysis of the chloride.	A whitish-gray metal, tarnishing in air.	The salts are topaz-yellow in color, and are similar to those of lanthanum.
Scandium Symbol Sc. At. wt. 45.1. At. no. 21. Valence III.	Occ. In the minerals euxenite and gadolinite. Prep. The metal has not been isolated.	The existence of this element, whose oxide was discovered in 1879, was predicted by Mendeléeff in 1869.	The chloride ($ScCl_3$) shows a characteristic spark spectrum.
Selenium Symbol Se. At. wt. 79.2. At. no. 34. Valence II, IV and VI. S. G. amorphous 4.27. monoclinic 4.47. hexagonal 4.8. M. P. amorphous 50°. monoclinic 170 to 180°. hexagonal 217°. B. P. 690°.	Occ. Free in some specimens of sulphur, and in combination with lead, iron and other metals, as in pyrites. Prep. (Amorphous) by reducing selenious acid (H_2SiO_3) by sulphur dioxide.	Three varieties are known: (1) red amorphous, soluble in carbon bisulphide, from which it is deposited as (2) red translucent monoclinic crystals, soluble in carbon bisulphide, (3) blue-gray metallic selenium, insoluble in carbon bisulphide. This last form conducts electricity many times better when exposed to light, and the better the brighter the light.	Selenium cells are used as indicators of intensity of illumination. The compounds strongly resemble those of sulphur. Hydrogen selenide is an evil-smelling inflammable gas. Selenic acid (H_2SeO_4) is a more powerful oxidizer than sulphuric acid, and dissolves gold.
Silicon Symbol Si. At. wt. 28.06. At. no. 14. Valence IV. S. G. amorphous 2.0. crystalline 24.9. M. P. 1200°. B. P. ca. 3500°.	Occ. Silicon dioxide (SiO_2) occurs as flint, quartz, quartz sand, etc. The igneous rocks are composed largely of silicates, and this element constitutes over 25% of the earth's crust. Prep. By reducing sand with coke in the electric furnace.	Amorphous silicon is a brown powder that burns when heated in air. Crystalline silicon forms black needles. It is less active than the amorphous variety and is attacked only slowly by a mixture of hydrofluoric and nitric acids. It unites with fluorine, however, at ordinary temperatures.	The "pigs" of silicon made at Niagara are used in steel-making. The ornamental varieties of quartz find uses as gemstones, as do several natural silicates. Silicon carbide, "carborundum" (SiC), is used as an abrasive. Sodium silicate solution is "waterglass," used to protect sandstone and to preserve eggs. Common glass is a mixture of sodium and calcium silicates.
Silver Symbol Ag. At. wt. 107.88. At. no. 47. Valence I. S. G. 10.53. M. P. 960°. B. P. 2050°.	Occ. Native, as sulphide (Ag_2S) often associated with galena; chloride (AgCl), etc. Prep. From lead by the Pattinson or the Parkes process; from the ores by the Mexican and other processes.	A white, highly lustrous, tough, very ductile and malleable metal, the best conductor of heat and electricity known. Liquid silver dissolves oxygen. It is unaffected by the oxygen of moist air, and its tarnishing is due to the action of hydrogen sulphide. It dissolves in dilute nitric and in concentrated hot sulphuric acid.	It is employed for articles of use and of ornament and for coinage. U. S. sterling silver contains 90% silver with 10% copper. Lunar caustic is silver nitrate. This salt and the halides of silver are extensively used in photography. For electroplating a bath of potassium argenticyanide [$KAg(CN)_2$] is used.

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Sodium Symbol Na. At. wt. 22.997. At. no. 11. Valence I. S. G. 0.97. M. P. 95.6°. B. P. 742°.	Occ. In the sea as chloride (NaCl); in salt deposits as chloride, borate, nitrate; in many complex silicates in rocks. Prep. By electrolysis of fused sodium hydroxide (NaOH).	A silver-white metal, as soft as wax, that may be welded at ordinary temperature. Like potassium it is very active, uniting directly with many other elements, and attacking water vigorously in the cold.	The metal is used in the manufacture of several chemicals. Sodium chloride (NaCl) is a necessity of life to most animals; and is used in the manufacture of hydrochloric acid, chlorine and sodium compounds. Sodium carbonate ($NaCO_3$, $10H_2O$) or washing soda, and sodium hydroxide (NaOH) are used for cleaning and in the manufacture of soap and chemicals. Baking soda is sodium bicarbonate ($NaHCO_3$). The sulphate (Na_2SO_4, $10H_2O$) is known as Glauber's salt; the thiosulphate, by photographers, as "hypo."
Strontium Symbol Sr. At. wt. 87.63. At. no. 38. Valence II. S. G. 2.55. M. P. ca. 800°.	Occ. As strontianite ($SrCO_3$) and celestine ($SrSO_4$). Prep. By electrolysis of the fused chloride.	A white metal, softer than calcium and harder than sodium, tarnishing to a yellow tint. Like calcium, it is active enough to attack water vigorously in the cold.	The nitrate and chlorate are used in pyrotechny for red fire. All volatile compounds color the Bunsen flame red.
Sulphur Symbol S. At. wt. 32.64. At. no. 16. Valence II, IV and VI. S. G. rhombic 2.06. monoclinic 1.96. M. P. rhombic 112.4°. monoclinic 119°. B. P. 444.9°.	Occ. Native, in combination with most metals as sulphides, and with some metals as sulphates. Prep. By melting the free sulphur away from the rocky matrix, and subsequent purification by distillation.	Natural sulphur is rhombic in crystalline form, yellow, brittle, of vitreous luster, and a poor conductor of heat and electricity. This and the monoclinic variety are soluble in carbon bisulphide, while amorphous sulphur is not. When heated, sulphur unites directly with most of the other elements.	Sulphur is used to prepare sulphur dioxide (SO_2), which is used in making sulphuric acid and sulphites, and for bleaching; also for vulcanizing rubber and in the manufacture of black gunpowder, fireworks and matches. Sulphuric acid (H_2SO_4) is to chemical industry what iron is to engineering.
Tantalum Symbol Ta. At. wt. 181.5. At. no. 73. Valence II, IV and V. S. G. 16.6. M. P. bet. 2250° and 2300°.	Occ. In tantalite and many other rare minerals. Prep. By the action of sodium on sodium tantalofluoride (Na_2TaF_7).	A hard silver-white metal, ductile and malleable when hot, of very high tensile strength. The hot metal can absorb 740 volumes of hydrogen. It is not attacked by aqua regia.	The metal was used for filaments for electric lamps, which possessed twice the efficiency of the carbon filament lamp.
Tellurium. Symbol Te. At. wt. 127.5. At. no. 52. Valence II, IV and VI. S. G. cryst. 6.3. M. P. cryst. 455°. B. P. 1400°.	Occ. Free and as tellurides. Prep. By reducing tellurious acid (H_2TeO_3) by means of sulphur dioxide.	The crystalline variety is white, has metallic luster, and conducts heat and electricity. The precipitated variety is black and of lower density. The element is related to sulphur but is more metallic in character.	The compounds find few applications. Telluric acid (H_6TeO_6) has basic as well as acid characters, in keeping with the position of the element between metals and nonmetals.
Terbium Symbol Tb. At. wt. 159.2. At. no. 65. Valence III.	Occ. In gadolinite, samarskite, and other rare minerals. Prep. The metal has not been prepared.		The salts show no absorption spectrum in the visible.
Thallium Symbol Tl. At. wt. 204.39. At. no. 81. Valence I and II. S. G. 11.8. M. P. 303°.	Occ. In crookesite, and in small quantities in many samples of iron pyrites. Prep. It is precipitated by zinc from a solution obtained by suitable treatment of the flue dust from sulphuric acid works.	A bluish-white lead-like metal, rather soft, malleable, but of low tensile strength. It decomposes water rapidly at red heat, and dissolves in dilute acids.	It forms two sets of salts, the thallous (*e.g.*, TlCl) and the thallic (*e.g.*, $TlCl_3$). All the compounds show a characteristic green line in the spectrum.
Thorium Symbol Th. At. wt. 232.15. At. no. 90. Valence IV. S. G. 11.0.	Occ. In monazite sand. Prep. By reducing potassium thorium chloride with sodium, or by electrolysis of the chloride in a mixture of fused potassium and sodium chlorides.	A metal with the color of nickel, that can be burnt in air. Hydrochloric acid attacks it but slowly.	The nitrate [$Th(NO_3)_4,6H_2O$] is used in making Welsbach incandescent mantles, which consist of 99% of ThO_2. All the compounds are radioactive.
Thulium Symbol Tm. At. wt. 169.4. At. no. 69. Valence III. M. P. 1700°.	Occ. In gadolinite and other yttrium minerals.		The salts are of a pale bluish color which is destroyed very easily by minute quantities of erbium.
Tin Symbol Sn. At. wt. 118.7. At. no. 50. Valence II and IV. S. G. 7.3. M. P. 232°. B. P. ca. 1600°.	Occ. As cassiterite (SnO_2). Prep. After roasting, the ore is reduced by heating with carbon.	A silver-white, rather soft, very malleable and ductile metal, practically unchanged in air. When heated, it may be burned in air. Dilute nitric acid is the only dilute acid that attacks it rapidly. When kept long at temperatures below zero C., ordinary tin changes to a brittle gray powdery modification. This form is the stable one below 20°.	Large quantities of tin are used in the tinning of iron for tinplate. It is a constituent of the alloys Britannia metal, pewter, solder, bronze, etc. Tin forms two sets of salts, stannous (*e.g.*, $SnCl_2$) and stannic (*e.g.*, $SnCl_4$). "Pink salt" [$(NH_4)_2SnCl_6$] is used in dyeing. "Mosaic gold" is SnS_2.
Titanium Symbol Ti. At. wt. 48.1. At. no. 22. Valence II, III and IV. S. G. 4.5. M. P. below 1850°.	Occ. As rutile (TiO_2) and in titanic iron ore ($FeTiO_3$). Prep. By reducing the chloride ($TiCl_4$) by means of sodium.	A hard, brittle metal, resembling polished steel in appearance, that may be forged at a low red heat. It dissolves in dilute sulphuric acid, and decomposes steam at 800°. It unites easily with nitrogen.	The element is very widely disseminated, though in small quantity. It is contained in the ashes of all plants.
Tungsten Symbol W. At. wt. 184.0. At. no. 74. Valence II, IV, V and VI. S. G. 19.3. M. P. ca. 2800°.	Occ. As wolfram ($FeWO_4$) and as scheelite ($CaWO_4$). Prep. By reducing tungstic acid (H_2WO_4) by carbon at a high temperature.	A hard, brittle, gray metal, attacked by chlorine only at 250°, although it can be caused to burn in air. It is slowly acted upon by dilute acids and even by water.	The metal is used for the filaments of incandescent electric lamps, giving an efficiency of 1.3 watts per candle power. Tungsten steel has 5% W. Sodium tungstates are used as mordants in dyeing.
Uranium Symbol U. At. wt. 238.17. At. no. 92. Valence III, IV, V and VIII. S. G. 18.7. M. P. ca. 1500°.	Occ. As pitchblende, which contains U_3O_8. Prep. By reducing the oxides with aluminium.	A white lustrous metal, tarnishing in air and attacking water slowly in the cold. It combines directly with many of the other elements.	All the compounds of uranium are radioactive in proportion to their uranium content. Glass to which uranium compounds have been added shows a greenish-yellow fluorescence.
Vanadium Symbol V. At. wt. 50.96. At. no. 23. Valence II, III, IV and V. S. G. 5.5.	Occ. In a few rather rare minerals. Prep. By reduction of the dichloride (VCl_2) in hydrogen.	A silver-white lustrous metal harder than quartz. It does not tarnish nor attack water at ordinary temperatures, but can be burnt in oxygen.	Vanadium added to steel even in small quantity (0.2%) increases the tenacity and elastic limit without reducing the ductility.

CHEMICAL ELEMENTS—Continued

Name, With Certain Data	Occurrence and Preparation	Properties	Chief Compounds and Uses
Xenon Symbol Xe. At. wt. 130.2. At. no. 54. Valence 0 B. P. 109°.	Occ. In minute quantity in the air, less than one volume in 100 million. Prep. By fractionation of liquid argon.	A transparent, colorless and odorless gas, very inert like its congener argon. It is the densest of the argon family.	It forms no compounds.
Ytterbium (Neoytterbium) Symbol Yb. At. wt. 173.6. At. no. 70. Valence III.	Occ. In gadolinite, euxenite and other rare minerals. Prep. The metal has not been isolated.		The compounds show a characteristic spark spectrum.
Yttrium Symbol Y. At. wt. 88.9. At. no. 39. Valence III.	Occ. In gadolinite, euxenite and other rare minerals. Prep. By electrolysis of sodium yttrium chloride.	A gray lustrous metal.	The chloride yields a characteristic, though complex, spectrum.
Zinc Symbol Zn. At. wt. 65.38. At. no. 30. Valence II. S. G. 6.9 to 7.2. M. P. 418.2°. B. P. 920°.	Occ. As zinc blende (ZnS), calamine ($ZnCO_3$), zincite (ZnO), etc. Prep. After roasting, the ore is reduced by coal, the metal distilling off.	A bluish-white, lustrous, brittle metal, that is malleable and ductile at 120°. It tarnishes in moist air, attacking water slowly in the cold and rapidly when heated in steam. It dissolves in dilute acids and in sodium hydroxide solution.	Sheet zinc is used for roofs and gutters. Iron is galvanized by dipping it in molten zinc, and so protected from rusting. Zinc is used for galvanic batteries and, alloyed with copper, to make brass. The salts are used in medicine; the chloride and sulphate yield antiseptic solutions.
Zirconium Symbol Zr. At. wt. 91. At. no. 40. Valence IV. S. G. 4.1.	Occ. As zircon ($ZrSiO_4$). Prep. By reducing the oxide (ZrO_2) with carbon in the electric furnace.	A hard gray metal, remaining bright in air and only slowly oxidized at a white heat. It is dissolved by aqua regia and by caustic potash solution.	The oxide is contained in some incandescent gas mantles.

SOME COMMON CHEMICAL SUBSTANCES

Common Name	Chemical Name	Chemical Formula	Remarks
Alabaster	Calcium sulphate	$CaSO_4 . 2H_2O$	A form of gypsum, fine in texture, varying in color, usually white. Used for ornaments.
Alum	Sulphate of potassium and aluminium	$KAl(SO_4)_2 . 12H_2O$	Colorless, crystalline. Used as a styptic or astringent.
Ammonia water or Aqua ammonia	Ammonium hydroxide solution	NH_4OH	Aqueous solution of the gas, ammonia (NH_3). Used in medicine and in the arts.
Aqua fortis	Nitric acid	HNO_3	Literally "strong water." Especially applied to ordinary commercial nitric acid.
Aqua regia	Nitric acid and hydrochloric acid	HNO_3 and HCl	Literally "royal water." A mixture of the two acids. It dissolves gold and platinum.
Arsenic, White	Arsenious oxide	As_2O_3	Also called "white arsenic," a poisonous oxide of arsenic. Used in medicine and in the arts.
Baking soda	Sodium bicarbonate	$NaHCO_3$	White, crystalline. Used in cookery and in medicine.
Bleaching powder	Calcium chloride-hypochlorite	CaCl(OCl)	Used for bleaching and as a disinfectant.
Boracic acid	Boric acid	H_3BO_3	Used in solution as a mild antiseptic.
Borax	Sodium tetraborate	$Na_2B_4O_7$	White crystalline. Used as an antiseptic and cleanser, and as a flux, in soldering and enameling.
Brimstone	Sulphur	S	Yellow substance. Used extensively in industry and in medicine.
Calcite	Calcium carbonate	$CaCO_3$	Native, crystalline. Known under various names, as calc-spar, etc.
Carbolic acid	Phenol	C_6H_5OH	Powerful caustic, poison, antiseptic.
Chalk	Calcium carbonate	$CaCO_3$	Soft limestone of marine origin. Much commercial chalk is calcium sulphate ($CaSO_4$).
Chrome yellow	Lead chromate	$PbCrO_4$	Brilliant yellow pigment.
Cinnabar	Mercuric sulphide	HgS	Brilliant red pigment.
Copperas	Ferrous sulphate	$FeSO_4 . 7H_2O$	Green, crystalline. Used in medicine and in dyes and inks.
Corrosive sublimate	Mercuric chloride	$HgCl_2$	Heavy, crystalline. Violent poison. Used in medicine and in the arts.
Cream of tartar	Potassium acid tartrate	$KHC_4H_4O_6$	White, crystalline. Found in grape juice. Used in baking powders and in medicine.
Epsom salt	Magnesium sulphate heptahydrate	$MgSO_4 . 7H_2O$	White, crystalline. Used as a cathartic, and in the arts. Originally made by boiling down the mineral waters at Epsom, England.
Glauber's salt	Sodium sulphate decahydrate	$Na_2SO_4 . 10H_2O$	Colorless, crystalline. Used as a cathartic and in soda and glass making.
Laughing gas	Nitrous oxide	N_2O	Colorless gas. Used as an anaesthetic in dentistry.
Limewater	Calcium hydroxide solution	$Ca(OH)_2$	Used as antacid in medicine and industrially.
Marsh gas	Methane	CH_4	Colorless gas, inflammable, found in natural gas and coal gas.
Muriatic acid	Hydrochloric acid	HCl	Usually applied to the commercial acid. Formerly thought to be derived from the oxide of an unknown element, "murium."
Niter	Potassium nitrate or Sodium nitrate	KNO_3 or $NaNO_3$	Potassium nitrate is known as saltpeter or Indian saltpeter. Chile saltpeter is sodium nitrate. Both nitrates are used as fertilizer, in explosives and in medicine.
Ocher	Ferric oxide	Fe_2O_3	An ore of iron, usually mixed with clay. With heat it becomes "burnt ocher." Used as a pigment.
Plaster of Paris	Calcium sulphate	$CaSO_4 . \frac{1}{2}H_2O$	White powder. With addition of water sets to form plaster casts, etc. Originally brought from a suburb of Paris.
Rochelle salt	Potassium sodium tartrate	$KNaC_4H_4O_6$	Colorless, crystalline, saline. Mild purgative. Discovered by Seignette, a druggist of Rochelle, France.
Rock salt	Sodium chloride	NaCl	Impure mineral, identical with halite.
Saccharin	Benzolsulfimide	$C_6H_4 . CO . NH . SO_2$	White, crystalline. Used as sugar substitute. From 300 to 500 times as sweet as sugar.
Sal ammoniac	Ammonium chloride	NH_4Cl	White, crystalline. Used in the arts and as an expectorant.
Sal Soda	Sodium carbonate	$Na_2CO_3 . 10H_2O$	White, crystalline. Also called "washing soda." Used in washing and in glass making.
Salteratus	Sodium bicarbonate or Potassium bicarbonate	$NaHCO_3$ or $KHCO_3$	Literally "aerated salt." Used as cooking soda.
Verdigris	Basic cupric acetate	$Cu(C_2H_3O_2) . HO$	The common acetate, dark green in color. Used in glazing.
Vitriol, oil of	Sulphuric acid	H_2SO_4	Applied to the concentrated acid. Formerly made by distilling green vitriol.

ETHNOLOGY

ANTHROPOLOGY is that science which studies man. Taken in its largest significance it includes so much and such diversified material that it is necessary to subdivide it. Four main divisions are usually recognized—somatology, ethnology, ethnography, culture history. Somatology, sometimes called physical anthropology, considers man as a living organism, in himself and in his relations to other animal forms. It includes anatomy, physiology and psychology. Ethnology and ethnography deal with races; the former is a philosophical, the latter a descriptive, science. The difference between them is the same as that between geology and geography.

Ethnology's Place Among Sciences. Ethnology is based on somatology; it defines the different races of mankind; it studies the great questions of origin, variation and distribution. Ethnography describes the different populations of mankind; it attempts to give a definite picture of the life and culture of each and every division of the human race; it deals little in theories, much in facts. Culture history studies the development of culture from lowest savagery to highest civilization; it is constructed from the facts supplied by ethnography.

The Scope and Field of Ethnology may be briefly indicated. The philosophical study of the human race involves investigation of the origin of mankind; it attempts to reconstruct the primitive type of man; it aims to locate man's first home; it defines the types and varieties of the human species; it seeks to follow the movements of mankind from its first home, and to present the facts of the present distribution of human varieties.

Origin of Man. The theory of evolution is as follows: Man is commonly recognized as no exception to the general rule. He is a part of animate creation, and is related by genuine ties of blood with other animals. His closest relatives are the various species of anthropoid apes living today in Africa, in southeastern Asia and in the adjacent islands.

There are four types which so much resemble man as to deserve the name of anthropoid apes—the gorilla, chimpanzee, orang-utan and gibbon. The gorilla and chimpanzee live in tropical Africa; the orang-utan and the gibbon live in the islands southeast from Asia, and in the neighboring portions of the continent. The gorilla is the largest of the four types, the different gibbons the smallest; all resemble man, but perhaps the nearest approach is in the chimpanzee and the orang-utan. Neither Darwin nor his followers have claimed that man is descended from any of the living types of anthropoids: that they and he alike have descended from a common ancestor; that they are collateral relatives.

Unity of Mankind. The old question of *monogenism* is no longer one of serious importance. Monogenism is the doctrine that all men have descended from a single stock; that all are of one blood. The counter-proposition that the different races of man have absolutely different origins, that they are different in blood, that all men are not brothers, is called *polygenism.*

In the early days of ethnology the battle between these two views was bitter. Naturalists held to the theory of the fixity of plant and animal species. It was recognized that within the range of a single species there might be variation, and varieties of species were recognized and clearly defined. But the idea that a species itself was temporary, and that one might go over to another through modification and by selection, was not recognized.

The question, then, was whether man formed a single species with several varieties or whether there were several human species. Certain tests of species had been determined. The two of most significance were these:

(1) BETWEEN THE DIFFERENT INDIVIDUALS OF A SPECIES THE RESEMBLANCE MUST BE GREAT AND THE VARIATION LIMITED.

(2) THERE MUST BE FERTILITY BETWEEN VARIETIES.

The scientific consideration as to whether man is of one or of several species clearly belongs to the biologist. As regards degree of resemblance it is certain that the different human races present less striking differences than those within the range of pigeons and domestic dogs. Whether the different races of mankind really breed well together and give rise to fertile offspring was much discussed, but, on the whole, may be assumed. Most of the old students, then, decided that mankind formed a single species with a number of varieties.

Today, however, the old question has little meaning. Biology no longer holds to fixity of species. All existing forms of life are believed to have been derived from previously existing forms through variation and selection. Under evolutionistic teaching, all types of man will eventually trace back to some single form, however different may be the present types of race. The question whether we shall speak of one or several species depends only at what point we choose to pass the plane which cuts across the twigs diverging from the parent branch. On the whole, the evolutionist of today chooses to assume a single species of mankind; but if he does so, he believes that variation early took place within the species and recognizes that the fundamental race types are old and have undergone comparatively little change in recent times.

Among recent forms of polygenetic (meaning "having many sources") theory the extreme is that of Sergi, which not only admits many species of man, but even several genera. Another recent phase of polygenetic thought is represented by Klaatsch, who believed there was a closer relation between local human races and the anthropoids of their district than between the races themselves. Thus he considered the Mongolic type of man and the orang-utan as offshoots from a common ancestor; the gorilla and Ethiopic type were similarly related; the chimpanzee and the Caucasic. Certain recent studies of blood reaction in human races and anthropoid apes have given support not only to polygenistic claims but also to the ideas of Klaatsch just stated. These are still open to question.

Original Type of Man. Various attempts have been made to reconstruct the primitive type of man. Years ago, de Quatrefages, on the basis of individual peculiarities occurring within the limits of all human races—peculiarities which he believed might be considered reversive—suggested that the first men were probably yellow of skin, red-haired and green eyed. While his view has been rarely accepted it has perhaps some elements of truth. It is possible to make a guess as to the structure of the earliest human occupants of western Europe, where various remains have been found in ancient deposits. Each fragment of human skeleton that has been found in glacial gravels or in cave-earth has given rise to bitter controversy. The number of pieces which have stood the test of critical examination and are unquestionably old is small. Among the most interesting of these remains are the skull-cap of Neanderthal and the skulls of Spy. Within a few years past, several discoveries of extraordinary importance have been made, and the list of authentic ancient pieces is double what it was a few years since. Rutot and others have recently summarized the whole discussion and we present a table based upon their evidence.

It is still too early to attempt a complete restoration of early man from these fragments. We may, however, say that even at that early time there were already variations. The type of Neanderthal presents many interesting points of resemblance to the anthropoid apes and suggests a being of low intelligence. At the same time, however, there existed forms with a far higher development.

The most interesting suggestion from the Table is that several markedly different types go far back in time and that the type considered by Osborn and English writers as the oldest had a remarkable skull capacity.

Man's First Home. It is possible that the discussion as to man's first home has been tinged by a survival of religious bias. The Garden of Eden of the Jewish scriptures was located in southwestern Asia. Most writers have, when they discussed the matter from the point of view of science, looked for man's home in the Asiatic continent. De Quatrefages claimed that it was natural to locate the place of man's appearance where his three great races—yellow, black and white—came into contact; where the different types of language also met. For him, the first home of man was in southern Asia, and from there migration started. Later writers looked farther south. Keane, for instance, believes that man originated on a land mass now disappeared, the old Indo-African continent, the existence of which has been proved by recent geological studies.

A hint as to the place of man's appearance comes from studying the range, past and present, of the anthropoid apes. We have already stated that the living species of anthropoids are confined to Africa and the Asiatic islands. It is probable that no forms strikingly resembling man have existed very far outside of the extreme range of living species. The much discussed and interesting "missing link" of Dubois, *Pithecanthropus erectus*, lived in Java. It may be fairly assumed that the place of man's origin was somewhere within the anthropoid range thus

suggested. It may also be quite safely claimed that a species like man, little adapted by nature to withstand a rigorous climate, originated in a region of mild temperature.

There is a tendency at present to move the first home farther north. The expeditions from the American Museum of Natural History, under Andrews, are seeking evidence for man's first home in Mongolia, an idea suggested by the geological history of the mammals.

Occasional suggestions that human evolution took place in America fail to meet support. Ameghino, in Argentina, believed he found ancestral forms in the palaeontological record of that region. Hrdlicka has decisively broken down his claim. The single tooth, found in Nebraska and at first championed by Osborn, has been abandoned.

Migrations. From the center of his original appearance man early started on migrations, which have been continued until, today, it may practically be said that he has penetrated every land area upon the globe. This is a fact without parallel. No other mammal can compare with man in its travels. The only approximation is the dog, which, as his friend and companion, has accompanied man upon his wanderings. It is legitimate study for the ethnologist to investigate the lines of migration, but a most difficult task. The present distribution of mankind, however, is a far more simple matter. The ethnological map of the world has been constructed with a fair degree of accuracy.

TABLE OF ANCIENT HUMAN REMAINS FROM QUATERNARY AND TERTIARY
(Based on Rutot and Osborn)

	Geological Divisions	Nature of Pieces and Locality	Types
Quaternary	Post-glacial	Skeletons, skulls or other fragments: from Duruthy, Cro-Magnon, Laugerie, Chancelade, Placard, Solutre, etc.	Cro-Magnon
		Mentone	Grimaldi Neanderthal
		Moustier, Neanderthal, Spy, La Naulette, Chapelle aux Saintes, etc.	
	Third Interglacial	Crapina	Neanderthaloid
	Second Interglacial	Trinil, Java	Pithecanthropus
	First Interglacial	Mauer, Germany	Heidelberg
Tertiary	Pre-glacial	Piltdown, England	Eoanthropus (Dawn-man)

RACES OF MAN

How many and what are the races of mankind? Authors differ greatly in their answers. At first sight this wide divergence of opinion between authors seems a serious matter; one feels as if the whole subject were in uncertainty and doubt; he is inclined to ask whether ethnology is actually a science. Huxley recognized two races; some other writers carried the number up to nearly forty. Cuvier, and French ethnologists generally, recognized three great races.

Blumenbach, who has profoundly influenced the general public and whose classification is that usually found in geographies and school textbooks, defined five—Ethiopian, Mongolian, Malay, American and Caucasian. His terminology has largely affected subsequent workers, even when they differed from him in their schemes.

The present tendency, as exemplified in three or four recent writers of repute, is toward the recognition of four main races. Thus Keane recognizes *Homo ethiopicus*, *Homo mongolicus*, *Homo americanus* and *Homo caucasicus*.

While this diversity between authors is to some degree a matter of regret, it need cause no serious distrust. The object of classification is convenience in study and the bringing together of things which are alike. When we compare the different ethnological schemes with one another, we usually find that they meet both these ends with fair success. All bring together groups which are alike, and but rarely do natural relationships of peoples seem to be disjointed.

We shall recognize the same types that Keane does, but shall apply to them the terms Ethiopic, Mongolic, American and Caucasic races.

Characters of Race. Topinard attempted to define the race types of the world. His study was the most careful and precise undertaken to that time. He based his types of races absolutely upon physical characters and made five features fundamental. These were the stature, head form, nose, hair and color.

Stature. In stature, man ranges from the tall Patagonian, with an average of six feet or more, to the pygmies of central Africa and the Negrito of the Asiatic archipelago. Among all races there is a sex difference in stature, and, in general, it may be said that the female will average one-sixteenth less than the male. In stating that any race or people is of a given stature it is meant that the average of stature in adult males is to be understood. The average stature of mankind is perhaps 1.65 meters.

The term "pygmy" is applied to the populations of smallest stature and the French writers have agreed to call all populations "pygmy" where the average stature of adult males does not exceed 1,500 millimeters. Sir William Flower set the limit for pygmy stature in English measure at five feet, which is practically the same thing. The ethnologist divides people on the basis of stature into tall tribes (1,700 mm. and up), medium (1,600 to 1,699 mm.) and short (below 1,600 mm.).

The Head Form is difficult to define in words. To convey it to the mind, certain measures are taken and a numerical statement made. The two most important head measures are the length and breadth. Actual length and actual breadth, however, have but little value, and it is common to compare the two, expressing the ratio between them in what is known as an "index."

Two head indices are commonly employed, one of which expresses the relation between the length and breadth of the skull and the other the relation of length and breadth upon the living subject. To the former the name "cranial" index is given; to the latter that of "cephalic" index. These indices are found by the same method, which is to divide the breadth by the length and drop the decimal point. Thus, if a skull measured eight inches in length and six inches in breadth, the cranial index would be 75. If, on a living head, the length were seven and one-half inches and the breadth five inches, the cephalic index would be 66⅔. There are no normal skulls with an index so low as 50 or so high as 100; that is, there are no normal skulls which are twice as long as they are broad, or which are as broad as they are long.

The indices are constantly employed in the defining of human races. The actual range as found in the averages of races is 69.4 to 88.7. Special terms are used to indicate the head form. Thus, brachycephalic (85.3 and up), mesocephalic (85.2 to 77), dolichocephalic (below 77). The Armenians are for most part brachycephalic with an index of 85.6; the Eskimo are dolichocephalic (76.8).

Nose. The form of nose is one of the best distinguishing characters of race. Here again, an index is calculated from two measurements—height and breadth. The nasal index is found by dividing the breadth of the nose by the height and dropping the decimal point. The range is from 60.4 to 107.9. A nose as wide as it was high would have a nasal index of 100; one which was half as broad as high an index of 50. Individuals with an index of 100 or more are not uncommon among negroes.

On the whole, the white peoples of Caucasic race have the narrowest and most prominent of noses. Three terms are used in connection with the nasal index—leptorrhinian (below 70), mesorrhinian (70 to 84.9), platyrrhinian (85 and up). The northern type of European is leptorrhinian, the Negrito of the Philippines is platyrrhinian.

Hair is one of the most distinctive marks of race. Huxley made it fundamental in his classification, and recognized two main divisions of mankind—the straight haired and the woolly haired. Various points should be observed regarding it. As regards its general form, hair may be straight, wavy, curly, crinkly or woolly. In cross section, it may be circular, oval or elliptical or flattened. White peoples, generally, have hair oval or elliptical in cross section; yellow peoples have hair with circular cross section; and blacks have distinctly flattened hair.

Hair differs racially in diameter, texture, abundance, distribution and angle of emergence. There are marked differences between races in the matter of calvity (baldness) and canity (graying). There are notable differences also in distribution and in the quantity and development of face hair. In color, race

differences of hair are black, brown, medium, light and blond. Red hair is found exceptionally among all races, but is typical of some sub-types. There are actually two types of red hair, one of which is blond, the other a variety of black.

Skin Color. The color of the skin varies with race. Its differences are so striking that they have attracted universal attention and in many attempts at classification the color basis is fundamental. It is difficult to suggest a serviceable series of color terms. There are no actual black populations and no truly white ones. For a careful discrimination, color scales are necessary, and ethnologists quite generally use a series of fixed color samples which they match with the skin of the subjects studied. The best known chromatic scale for use in race study is that of Broca, where some thirty-four shades are discriminated. In ordinary practice a list of half a dozen terms is employed.

Four Great Races. The four great races may be characterized as follows:

Ethiopic. Color, from brown to almost black; generally dolichocephalic; forehead, frequently retreating with heavy arches over the orbits; prognathic, that is, the lower part of the face notably projecting; the cheek bones do not project notably forward and anteriorly; the nose is broad and flattened, platyrrhinian; the eyes are large and prominent and lustrous, dark brown or black in color; the hair is black, frizzly or woolly, and presents a flattened cross section; the stature is above the average of mankind at 5 feet 10 inches. The pygmy populations differ from the normal Ethiopic type in stature, in head form, tending toward brachycephaly, and in hair color, frequently a reddish brown.

Mongolic. Color, a lighter or darker yellow; brachycephalic; the forehead fairly developed and without conspicuous orbital arches; the general impression given by the face is flatness and broadness with prominent forward development of the cheek bones; the nose is generally small and mesorrhine; the eyes black, with narrow almond-shaped opening, which appears to be oblique on account of a fold of skin at the inner edge; hair black, lank, coarse, circular in cross section; stature below the average at 5 feet 4 inches.

American. Color, brown with a reddish or yellowish tinge; mesaticephalic; large coarse features; forehead well developed and usually slight prognathism; cheek bones are prominent; nose mesorrhine, prominent, large, often aquiline; eyes small, round, straight, sunken, black; hair, black, lank, coarse, long, round; the face is usually beardless and there is little body hair; stature above the average at 5 feet 8 inches.

Caucasic. Color, ranging from white to almost black and presenting in white peoples distinctly fair and dark varieties; both types of head form occur, combined with both fair and dark colors; the face usually harmonizes in its form with the head form; prognathism rare; cheek bones not projecting; leptorrhine; eyes straight, rather large, and varying in color from light gray or blue to dark brown or black; hair, wavy, oval or elliptical in cross section, varying from flaxen to black; beard usually developed and body hair abundant; stature variable from tall to average.

The Ethiopic Race may be divided into continental and island divisions. The continental blacks occupy Africa from the Sahara Desert southward. The insular group is found in Melanesia and it is customary to add the native population of Australia to this race. Both on the continent and in the islands, two sharply contrasted types are found—the large Negroes and the small, or pygmy, populations.

Pygmies. The pygmies present the typical hair, features and general characters of the race, but in the average of adult males fall below 5 feet in stature. In central Africa they occur in little groups scattered over a wide area in the midst of large black peoples. They have practically no agriculture and depend on the chase for food, representing the culture stage of savagery. Their hair is frequently of a reddish or grayish brown. They are not to be considered a dwarfed or degenerate population, but a well-developed and active people of a type among the oldest known.

A curious condition of commensalism (meaning "to eat at the same table") usually exists between these little people and their large neighbors. The populations among whom they live are settled agricultural peoples, living in large and well-built villages. The pygmy settlements are usually at the edges of these towns, and a constant trade exists between the two groups. The little people bring fresh meat, ivory, honey and other natural products and receive in trade field products, cloth and iron.

To the little blacks of the island world, of whom those living in the Philippines are typical, the name "Negrito" is usually applied. They present the same physical peculiarities, stage of culture and mode of living. They live in practically the same relations with the neighboring Malays that the pygmies do with their large neighbors.

Bushmen. It is customary to group the Bushmen of southern Africa with the pygmies. They present some interesting points of difference. Their skin has a distinct yellowish tinge; they live in little wandering groups, taking refuge in caves and rock-shelters; they are hunters, but there is no distinct commensalism between them and their Bantu neighbors; they delight to mark their cavern walls with crude but lively representations of the animals they pursue. These peculiarities, to a less degree, mark the pygmies of central Africa. They are also found in the Hottentots, neighbors of the Bushmen, usually considered to be the result of intermarriage between them and the Bantu of the region.

Negroes. The large continental blacks live in good towns, depend upon the product of the fields (cultivated by women), or, especially toward the south, upon herds of cattle. Two great divisions are recognized—the true Negro of the Soudan district and the Bantu populations farther south.

In the true Negro the characteristics of the race already mentioned are carried to their fullest development; blackness, coarseness of features, flatness of nose, prognathism with accompanying thickness of lips, and dolichocephaly are emphasized in them. The Bantu present a fine, chocolate brown tint, more regular and, to the eye, pleasing features; prognathism is rarely pronounced and the head is by no means markedly dolichocephalic.

Melanesians. In the islands, the large blacks include the Papuans of New Guinea and the Melanesians of Fiji, New Caledonia, the Solomons and other island groups. Their life is interesting and has been the subject of much study. Dark colored, woolly haired, dolichocephalic, platyrrhine and of good stature, they are actually comparable with the big blacks of Africa.

The Mongolic Race is the most populous of the divisions of mankind. There is reason to believe that of the great races it perhaps nearest approaches the primitive stock of humanity. It is vigorous, hardy and expansive. Its primitive home is the great continent of Asia, which is still chiefly occupied by it. The race presents two chief divisions to which Keane gives the names Mongolo-Tatar and Tibeto-Indo-Chinese.

The Mongolo-Tatar is the northern in position. It has spread from Asia across northern Europe and occupies today the north of Russia and a considerable area of Scandinavia. To it belong the great wandering hordes of Siberia—Mongols, Kalmucks, Buriats, Tungus, Yakuts and the like; to it also belongs the great Finno-Tatar group—with Tatars, Turki and Ugrians. To this belong the Finns, Magyars and Bulgarians. In the far north are the Samoyeds and Lapps, the latter a people of small stature, who raise reindeer in the north of Sweden and Norway. To the great Mongolo-Tatar mass also belong the Koreans and the Japanese, relatives in blood and language. The Koreans are relatively pure Mongols, the Japanese much mixed with other elements, as we shall later see.

The Tibeto-Indo-Chinese division includes the Tibetans, the Chinese proper and the great mass of people in Indo-China and southeastern Asia, such as the Siamese, Burmese and the people of Annam. They are sedentary peoples, depending upon agriculture, with towns and cities, a dense population with distinctive culture, a true civilization. Linguistically, the southern group differs profoundly from the Mongolo-Tatar. Chinese and Japanese represent totally different types of language.

Eskimo. Besides the two great divisions mentioned, the Mongolic race includes two interesting extra-continental groups—the Eskimo and the Oceanic Mongols, or Malays. Taxonomically, the Eskimo present a difficult problem. In color, face, features, stature—in fact, in the whole general impression—they are clearly Mongolic. But they are at the same time dolichocephalic; the Eskimo skull is one of the most sharply marked; it is long and narrow, has square jaws and ridged vault to the degree that, viewed directly from in front, it gives a distinct pentagonal outline.

The Eskimo occupy the whole arctic coast of North America from south and western Greenland to the western end of Alaska and overlap into eastern Asia. Throughout this enormous range of thousands of miles they present remarkable uniformity in type, language and mode of life. The area occupied is chiefly American, not Asian; and the bulk of Eskimo population is found in the new world.

Malays. The Oceanic Mongols, or Malays, occupy the islands of Malaysia, the Malay peninsular and a part of the great island of Madagascar off the east coast of Africa.

Blumenbach considered the Malay one of the fundamental populations of mankind. It presents a fairly well-marked type, which, however, may be included in the Mongolic. The Malays and the Malayan peoples (for the word "Malay" proper is used chiefly in ethnology for those in the peninsula) are good seamen.

The American Race. Keane refuses to recognize the Malays as distinct, but insists upon separating the American type from the Mongolic. For him they are an off-shoot, but one of ancient date, which has had ample chance to develop peculiar characters in the American area. Contrasted with the other great races it presents a notable degree of physical uniformity. Writers have often said: "When you have seen one American Indian you have seen all; the American Indian presents the same type from the cold waters of the Arctic to the cold waters of Cape Horn."

This uniformity is striking but not absolute. Careful study shows tall and short tribes of American Indians, from the Patagonians, who are perhaps the giants of mankind, to Otomi, who almost touch the limit of pygmy height. There are long headed and short headed tribes, light and dark—from almost black to almost white; there are tribes with large faces and coarse features, like the Sioux, and tribes with soft and mild faces and delicate features, like the Chinantecs.

The American Indians present a notable uniformity in culture. While writers usually have claimed a single origin for the American peoples, it seems more reasonable to assume that immigrants have come by many routes from many regions. Within the new environment the fragments of old populations have approximated to each other until we have the present condition of relative uniformity.

The Caucasic Race. The continent of Europe is chiefly occupied by people of Caucasic race. Light whites and dark whites are readily distinguished. No section of the world has presented more serious problems to the ethnologist and no race is more difficult of satisfactory discussion than the Caucasic.

So far as Europe is concerned, Ripley recognizes three races: the northern, which is fair, tall, dolichocephalic; the Alpine, which is short, dark and broad headed; the southern or Mediterranean, which is short, dark and long headed. This classification is attractive for its simplicity. It seems indeed to be too simple, and with its acceptance, points of importance are lost from sight and real distinctions fail to be recognized.

Aryan Whites. Deniker recognizes ten types of European whites speaking Aryan tongues, which he groups under six races and four sub-races. His characterization of these types is as follows:

(1) *Northern.* Very lofty stature (1.73 m.); dolichocephalic (76-79); fair; wavy hair, sometimes reddish; light eyes, usually blue; ruddy white skin; long face; prominent, straight nose; *e.g.*, Swedes.
  (a) *Subnorthern.* Tall; mesocephalic; fair; straight hair; angular face; turned-up nose; *e.g.*, Letto-Lithuanians.
(2) *Eastern.* Short (1.63 m.); moderately round-headed (82-83); fair; straight light-yellow or flaxen hair; square-cut face; eyes blue or gray; nose frequently turned up; *e.g.*, Russians.
  (a) *Vistulian.* Very short; mesocephalic; fair; *e.g.*, some Poles.
(3) *Ibero-Insular.* Short (1.61–1.62 m.); dolichocephalic (73-76); dark; hair black, often curly; very dark eyes; tawny skin; straight or turned-up nose; *e.g.*, Spaniards.
(4) *Western*, or *Cevenole.* Short (1.63–1.64 m.); very rounded skull (85-87); dark; brown or black hair; light or dark brown eyes; rounded face; thick-set figure; *e.g.*, central French.
(5) *Littoral*, or *Atlanto-Mediterranean.* Tall (1.66 m.); moderately dolichocephalic or mesocephalic (79-80); dark; hair and eyes very dark colored. Always near the Mediterranean coast.
  (a) *Northwestern.* Tall; sub-dolichocephalic; chestnut hair, often brown; *e.g.*, Welsh.
(6) *Adriatic*, or *Dinaric.* Tall (1.68-1.72 m.); brachycephalic (85-86); dark; brown or black wavy hair; dark eyes; straight eyebrows; elongated face; delicate, straight or aquiline nose; slightly tawny skin; *e.g.*, Montenegrins.
  (a) *Sub-Adriatic.* Less tall (1.66 m.); less brachycephalic (82-85); lighter hair and eyes; *e.g.*, Luxemburgers.

These are all truly European types, speaking related languages.

Non-Aryan Whites. There are, however, other Caucasic peoples; thus, in the region of the Caucasus itself, a district of extraordinary mixture and ethnic confusion, are many interesting peoples. It is from this district of Georgians and Circassians that the name applied to the whole great race was drawn. The Basques of the Pyrennean district, divided politically into French and Spanish Basques, are white men, Caucasian, European, but not included in Deniker's types, being unrelated in language to the races of Aryan Europeans.

The whole of north Africa is occupied by peoples who are neither Ethiopic nor Mongolic, and who, though dark in skin for the most part, are regularly classed in the Caucasic race. Although, in their entirety, the general name Hamitic is given to them, some of them have been profoundly influenced by Semitic peoples and languages.

Many fine types occur within this area, which, of course, includes the Egyptians, past and present, the Libyans and the Berbers. While these peoples are for the most part dark, some remarkable groups of notably blond types occur among them. That these blond types are ancient is clearly shown by the wall-paintings of old Egypt, where the Libyan is regularly represented as blond. To the Caucasic race belong also the brunette populations, ancient and modern, who speak the pure and typical Semitic languages—Hebrews, the modern Arabs and their neighbors. With them, we enter Asia.

Asiatic Caucasians. In Asia, also, are Caucasic peoples, some of them speaking Aryan languages, in Persia, Afghanistan and parts of India. Caucasic elements in Asia date far back, and there is good evidence of their existence and influence even in that section of the great continent which is occupied by Mongolo-Tatar populations.

The Ainu of Yeso and Saghalien are a Caucasic people. They are the remnant of the aboriginal population of Japan. Perhaps they occupied the entire archipelago before the coming of the Japanese from the continent by way of Korea. They are dirty white in color; have abundant wavy hair, elliptical in cross section; horizontal, large expressive eyes; almost European features; abundant body hair and heavy beards. They are mild in disposition and in culture are almost in savagery. Their language differs notably from Japanese in structure and words.

In India are the Todas, whom Keane considers Caucasic. In face, features, hair and heavy beards, in yielding character, they present considerable analogy to the Ainu. They are, however, cattle raisers, and their whole life is wrapped up in the care of their animals. There are in other parts of Asia scattered fragments of populations which one and another writer have suggested as Caucasic and it is not impossible that continuous populations of inoffensive and weak Caucasic type once occupied the whole of eastern Asia and that they have been broken and separated by the flood of Mongolics coming from the west. The present tendency is to recognize the existence of Caucasic people in the island world.

Indonesians. The term "Indonesian" is much used for certain people of Malaysia who do not present the true ("Malay") Mongolic type. It is assumed by those who use the term that these Indonesians are in large part Caucasic, modified by Malay or other island blood. The Polynesians, too, are largely claimed at present as Caucasic. These peoples present a handsome, attractive type; of good stature, well built, with faces of regular features, they are beautiful, by our standards.

GEOGRAPHICAL DISTRIBUTION

In general, each continent has a distinct type of mankind. Asia has its Mongolic type; Europe and northern Africa its Caucasic type; south Africa its Ethiopic type, and the double continent of America its American type. Even Australia has a definite race type. While this is true, there has been so much of movement, interpenetration and admixture that the population of no great land area is now uniform.

European Peoples. Europe, with northern Africa, is the true home of the Caucasic race, but contains Mongolic peoples as well. In the accompanying table of European peoples by countries the main or fundamental population is given in one column, the more important secondary elements in another.

Asiatic Peoples. Asia is the continental home of the Mongolic race, which still forms the greater part of its population, but a large Caucasic element has been present since ancient times and there is local mixture of Ethiopic blood. Deniker recognizes eleven physical types, which have intermingled to produce the Asiatic peoples of today. Five of them are peculiar to Asia—Dravidian, Assyroid, Indo-Afghan, Ainu, Mongolian; six occur elsewhere—Negrito, Indonesian, Arab, Ugrian, Turkish and Eskimo. Six of these are Caucasic—Dravidian, Assyroid, Indo-Afghan, Ainu, Indonesian, Arab; four are Mongolic—Mongolian (Tibeto-Indo-Chinese) Ugrian (Mongolo-Tatar), Turkish (Mongolo-Tatar), Eskimo; one is Ethiopic—Negrito.

Dravidian applies to the brown aboriginals of southern India, who are short of stature, dolichocephalic and with curly or wavy hair. Peschel made of them a great race type. Their position among races has been disputed, but in our four-race classification they must be called Caucasic.

Assyroid is so called because the type is common in the wall sculptures of old Assyria. It is well characterized, with tawny-white skin, narrow hooked nose with thick lips, brachycephalic, hair wavy or curly. It is the Armenian type and the oft-mentioned "Jewish" type is fundamentally Assyroid. In our scheme it is Asiatic Caucasic. So, too, is Indo-Afghan, the type of the invading conquerors of part of India. It has clear brown skin, black wavy hair, narrow straight or convex nose, dolichocephaly, tall stature.

The Arab, typical Semite—though the word Semitic is properly linguistic, not ethnic—is dark, with black wavy hair, dark eyes, long elliptical face, dolichocephalic head, aquiline nose, prominent occiput.

Jew. This term should be used in only a religious sense; in so far as it has ethnic application it is fundamentally Assyroid or Arab or both; but it is everywhere mixed and approximates the people of the surrounding populations. Jews, of course, exist the world over. Gypsies, also world-wanderers, probably began in India and are Indo-Afghan, at least in part.

African Peoples. To draw up similar tables of the population of other continents would be more difficult and less satisfactory. The population of Africa falls into two well-marked divisions. Northern Africa to the Sudan must be ethnically joined to Europe. Brinton emphasized this fact by making one continent of the two land masses, to which he gave the name Eurafrica. Its population is Caucasic, though many of its peoples are dark of skin. In features, head-shape, hair, nose, they are clearly related to European peoples. Among them are Berbers, Libyans, Egyptians, Nubians, Abyssinians. Collectively these north-African peoples are called Hamitic but they have been strongly influenced by Arab (Semitic) hordes which have swept over the area.

On the southern border there is much mixture with Negro blood. To the rest of Africa, Brinton applies the name Aust-Africa. It is divided between true Negroes in the north and the Bantu peoples of central and south Africa. Bantu is a linguistic term, and the division between the two masses of population is primarily linguistic. But there are physical differences also. Scattered amid the big blacks of central Africa are the pygmy groups, and in the Kalihari Desert region of the south live Bushmen.

American Peoples. The great double continent, America, was occupied solely by the American race, except along the northern coast, where Eskimo live. American Indians have never been seriously classified upon the basis of physical types, due to the uniformity already mentioned.

Language is the basis generally employed in dividing the race into study groups. There are hundreds of languages spoken among them, and even language families, or independent stocks, number scores. Powell recognized fifty-eight linguistic families in North America north of Mexico. Brinton divides the double continent into five geographical regions—North Pacific, North Atlantic, Isthmian, South Pacific, South Atlantic. North Pacific, North Atlantic and Isthmian make up North America; the other two regions constitute South America.

While this division is geographical, Brinton emphasizes the fact that these regions are really culture areas as well. In such an article as this, further detail would but confuse by introducing a multitude of tribal names.

Oceanic Peoples. The Island World is not a unit ethnologically. It includes four well-marked, clearly characterized, areas—Malaysia, Melanesia, Australasia and Polynesia.

Australasia. These may be separated into the Australian and the Tasmanian types. The latter seems more primitive and approaches, perhaps, the Melanesian. The Australians are fundamentally blacks, Ethiopic, but have been influenced by Dravidian or other elements until they have lost the woolly hair. With chocolate brown skin, broad nose, dolichocephaly, and medium stature they present a fairly uniform type, which some authors class among the great races.

Melanesia includes New Guinea or Papua and a number of groups of smaller islands. The true Papuan shows a fairly distinct type, but he is usually included with the rest under the general term Melanesian, which includes all the large Oceanic Negroes, Ethiopic in race.

Malaysia extends from Madagascar to Melanesia, thus lying west of the two areas just considered. It includes the great islands of Sumatra, Java and Borneo; also Celebes, the Philippines, and many smaller islands; Formosa, ethnically, is Malayan. Malays form the chief population, but Melanesians have had local influence, and Negritos, little blacks, occur at many points.

The most interesting portion of Malaysia is the Philippine archipelago. Its ethnology is complicated. After making the first serious study of it, Blumentritt suggested the following theoretical explanation: Four populations occur—(1) the aboriginal Negritos; (2) a great list of tribes representing an early Malayan immigration, tribes like the Igorot, Ifugao and others; (3) a second Malayan immigration of people much further advanced in culture, represented by the civilized "Cristiano" populations, which form the bulk of the Philippine peoples today, including the Tagals, Visayans and Ilocano; (4) a third Malayan immigration, Mohammedans, the "Moros" of Mindanao and the Sulu islands. This immigration was just well under way when the Spaniards appeared in the sixteenth century and checked it. There seems to have been a northward streaming of Malayans from the Philippines and Formosa that carried Malay blood and influence into Japan. The Japanese are not pure Mongols, but owe much to Malays.

Most writers today would consider Blumentritt's (2) Indonesian rather than Malayan.

Polynesia is singularly uniform in population. There are local mixtures, of course, where the area touches Melanesia.

The recent streaming out of white men into all parts of the world has had a remarkable influence on race vitality and characteristics. Today in America and Australia, in Polynesia, and even in Africa, the original populations are disappearing or subordinated.

Table of Peoples of European Countries

Country	Chief or Foundation Peoples	Subordinate or Local
Austria.	Northern.	Western. In south, Adriatic.
Belgium.	Northern (Flemish). Western (Walloon).	Northwestern.
British Isles.	Northern, Subnorthern.	Northwestern; in Wales and Ireland.
Bulgaria.	Bulgars. (Mong.-Turko-Finn.)	Mixed with Slav elements.
Denmark.	Northern.	Along coast. Western.
France.	Western or Cevenole, in highlands.	Northwestern, in northern lowlands. Littoral in south. Adriatic. Ibero-Insular.
Germany.	Northern, in lowlands.	Sub-Adriatic. Western.
Greece.	Diversified and uncertain.	
Italy.	Adriatic in north. Ibero-Insular in south.	Littoral. Western.
Montenegro.	Adriatic.	
Netherlands.	Northern. Subnorthern.	
Norway.	Northern. Lapps, etc., (Mong.) in north.	Subnorthern and Northwestern, along coasts.
Portugal.	Ibero-Insular.	Northwestern.
Rumania.	Turki (Mong.). Western elements.	
Russia.	(Cauc.) Northern. Subnorthern. Eastern. (Mong.) Lapps. Finns, Samoyeds.	Vistulian (Poles). Adriatic.
Servia.	Adriatic.	
Spain.	Ibero-Insular.	Western, north coast; Littoral, south coast.
Sweden.	Northern. Lapps and Finns (Mong.)	Subnorthern and Northwestern along coasts.
Switzerland.	Cevenole, or Western.	Adriatic. Sub-Adriatic.
Turkey.	Turki (Mong.).	

Table of Peoples of Asiatic Countries

Country	Chief or Subordinate Peoples	Subordinate or Local
Afghanistan.	Indo-Afghan (Cauc. of Aryan speech).	Assyroid (Cauc.).
Arabia.	Arabs. Syrians (Cauc.—Semites).	
Baluchistan.	Baluchi (Cauc.—Indo-Afghan).	Arab. (Cauc.—Semitic). Negroid.
Burma.	Burmese.	(See Indo-China).
China.	Chinese. (Mong.—T.-I.-C.).	Lolos, Miautse (perhaps Cauc.). Other fragments of aboriginal peoples.
India.	In north, Mongolic.	In Punjab-Deccan; brachycephal Cauc.?
	Ganges and Indus valleys, Aryo-Dravidians.	Ceylon; Veddahs, aborigines (Cauc.?).
	In south; Dravidians.	
Indo-China.	Cambodians. Annamese. Burmese. Thai. (Shans. Laotians. Siamese.)	(Aboriginal "Indonesians" mixed with incoming Mongolic peoples.) Negrito.
Japan.	Japanese (Mong.—K.-J.).	Ainu (Cauc.). Much Malay influence.
Korea.	Koreans (Mong.—K.-J.).	Trace of Caucasic elements.
Persia.	Persians (Cauc. of Aryan speech).	Semites (Cauc.). Turki (Mong.—M.-T.).
Siam.	Siamese (Mong.—T.-I.-C.).	(See Indo-China).
Siberia.	Mongols, Tungus, Tatars, Yakuts, etc.	
Tibet.	Tibetans (Mong.—T.-I.-C.).	
Turkey.	Turki (Mong.—M.-T.).	Assyroid (Cauc.).

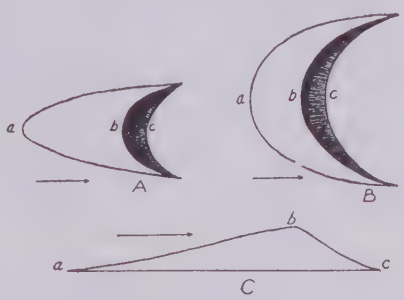
GEOLOGY

GEOLOGY is the history of the earth and its life. It is, moreover, ancient history rather than modern; and the record of its events are written in the rocks of the earth's surface rather than in ancient volumes. Geology therefore is one of the most comprehensive of the sciences, and it utilizes as its tools many of its companion studies such as physics, chemistry, astronomy, zoölogy and botany. So broad a science of necessity must have many subdivisions. *Cosmic geology* deals with the earth's relations with other astronomic bodies; *petrology* is the study of rocks; *structural geology* deals with the arrangement of the rocks; *dynamic geology* is concerned with the forces involved in geologic processes; and *physiography* treats of the earth's surface features. *Paleontology* is the study of fossils and faunas that have lived in the past; and *historical geology* is that phase of the science which deals with the succession of events both physical and organic throughout the earth's long history. Of the other branches of the subject which might be mentioned, *economic geology*, or the industrial application of geologic knowledge, is the most important to man. *Geography* may be regarded as a phase of modern geology.

PHYSICAL GEOLOGY

Earth Relations. Although the earth is supremely important to us, it is but a third-rate planet revolving about a second-rate sun. A number of the most important geologic processes, however, and indeed life itself are dependent on the earth's astronomical relations, which are discussed in detail under the chapter on "Astronomy."

Major Divisions of the Earth. The materials of the earth may be separated naturally into three major divisions: (1) the atmosphere, (2) the hydrosphere and (3) the lithosphere.



Atmosphere. Although extending far above the earth, the atmosphere nevertheless revolves and rotates as a fundamental part of it. Except when the wind is strong, we are unconscious of its weight, yet the atmosphere is estimated to comprise $\frac{1}{1000000}$ of the earth's great mass; and it exerts a pressure of about fifteen pounds per square inch at sea level. The density of the air diminishes rapidly upward, but from theoretical lines of reasoning it seems likely that the rarest parts of the earth's atmosphere extend out beyond the orbit of the moon.

The atmosphere is the most active of the major divisions of the earth, and its effects upon the other divisions are so great that it may be regarded as one of the most important agents of change in the geologic history of the earth. Its function in sustaining life is obvious.

Hydrosphere. The hydrosphere comprises all of the waters of the earth's surface, and it makes up about $\frac{1}{3000}$ of the earth's mass. Compared with the ocean, all of the other bodies of water are small, yet of all the geologic agencies shaping the earth's surface, running water is the most obvious and apparently the most efficient. In the form of rainfall, surface streams, underground waters, currents and waves, the hydrosphere is continually altering the earth's facial expression. It is eternally carrying sediment from the higher land to the basins where it is deposited.

Lithosphere. The lithosphere (rock sphere) is the only one of the three major divisions of the earth which is truly a sphere, for both the atmosphere and the hydrosphere are shells which penetrate the solid earth only to shallow depths. The greater part of the lithosphere is composed of solid rock, but at most places it is covered by a surface veneer of loose material such as soil, clay, gravel, sand and fragmentary rock, which is collectively known as *mantle rock.*

The solid rock is nowhere very far beneath this mantle, and at many places it appears directly at the surface. This solid rock is made up of many diverse varieties, all of

Dunes

A. and B. Sand dune shapes known as *barchanes*. C. Section through dune. Arrows show direction of wind.

which may be grouped into three main classes. The *stratified* rocks are layered, and they are similar in composition and in bedding to those sediments which are forming on the sea bottom today. The *igneous* rocks are hardened lavas, or other products of volcanic processes. *Metamorphic*, or altered rocks, have undergone physical and chemical alteration since their formation. These rocks have been derived from either the igneous or the sedimentary type chiefly through the agencies of heat, pressure and underground water.

Work of the Atmosphere. *Mechanical Work.* The mechanical work of the wind depends upon its movements. The transportation of dust by the wind is essentially universal, the particles finding their way to the interior of tightly closed drawers and even falling upon the decks of steamers in mid-ocean. During the eruption of Krakatoa, in Malaysia, in 1883 large quantities of dust were shot up to great heights by the force of the explosion. This dust, carried by upper air currents, completely encircled the earth and made red sunsets for several months. In some parts of China there are very thick deposits of a fine-grained, wind-blown dust known as *loess*, out of which the Chinese have carved walls, homes, and even entire villages.

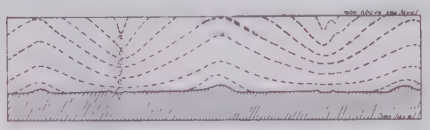
Winds do not commonly lift sand far above the surface, and therefore surface obstacles interfere with the movement and cause it to drift. It thus is aggregated into mounds and ridges known as *dunes*. The dunes may attain heights of several hundred feet, but more commonly they are from ten to thirty feet in height. The shape of the dune depends on many factors such as the strength and duration of the wind, the source of the sand, and the shape of the obstacle which started the dune. With fairly constant winds and abundant sand, dunes in cross section are seen to be relatively steep on the lee side and gently sloping on the windward side. The angle of slope on the lee of the dune is rarely as great as 30°, and on the windward side it is generally less than 15°. The continual transference of material from the windward to the leeward side causes dunes to march steadily in the direction of the prevailing winds. Thus entire forests are overwhelmed, covered, killed and finally again exposed by the shifting sands. The church at the village of Kungen, on the east shore of the Baltic Sea, was covered by a dune in 1809 and revealed again sixty years later by the migration of the sands.

The abrasive effect of the wind depends on the materials that it can carry. In semiarid regions the solid rock may be carved into fantastic spires and pinnacles by the sand constantly being blown against its surface.

Chemical Work. The atmosphere is an efficient chemical agent only in connection with water, for dry air has little effect on rocks or soil. The important atmospheric processes of a chemical nature are *oxidation*, *carbonation* and *hydration*. Oxidation is the union of oxygen with some constituent of the rock to form an oxide. Carbonation is the union of carbon dioxide with rock constituents to form carbonates, and hydration is the union of water with constituents of the rock. These processes operate most efficiently in hot, damp regions, but they are of importance in all climates.

Work as a Conditioning Agency. In addition to its chemical and mechanical work, the atmosphere is also a conditioning agent. Changes of temperature tend to break up rock. The alternation of heating and cooling of rock by day and night causes its disintegration. Atmospheric temperature is the chief factor governing evaporation, it is important in the circulation of the water vapor and it controls its precipitation in the form of rain or snow. In addition the water vapor of the air, together with its carbon dioxide, acts as a thermal blanket which permits the passage of the sun's radiant energy through it, but does not readily permit the heat generated at the earth's surface to spread out into space.

Work of Running Water. *Destructive Work.* It has been estimated that 30,000 cubic miles of water in the form of rain or snow fall upon the surface of the earth every year; and more than one-fifth of this great total is carried to the sea by rivers. Since many of these streams descend from great heights, their total energy is tremendous and the amount of sediment which they carry during a year is almost incalculable. The destructive work of some sluggish streams is not readily apparent, but swift-flowing rivers may be seen to wear away their banks from year to year, and streams in flood may excavate new channels in the course of a few hours.



Streams which flow the year round are called *permanent streams*, whereas those which flow only after rains or seasonally are known as *temporary* or *intermittent*. All permanent streams and most temporary ones flow in depressions known as *valleys*. Very small depressions in which water runs only after showers are called *gullies*, and somewhat larger temporary stream courses usually are referred to as *ravines*. The smallest gullies unite to form larger ones, which in turn join others to form ravines which lead finally into valleys.

After heavy rainfall the run-off becomes concentrated in natural depressions which are enlarged into gullies by the erosive effect of running water. The lengthening of these drainage depressions takes place chiefly at their upper ends and is known as *headward erosion*. While the depression is being lengthened by this process, it is also being widened by *lateral erosion*. It appears, therefore, that many valleys are developed by the run-off of a series of showers, but if the source of the water were run-off only, all surface streams would cease to flow shortly after rainfall. As the valley of an intermittent stream is cut deeper, however, the periods when it is dry are shorter; and when it is at last sunk below the *permanent ground water table* it becomes a permanent stream, no longer dependent directly upon rainfall. Since a valley ordinarily works headward, its lower and older course is likely to have a permanent stream, while the younger and upper parts are occupied by a temporary stream.

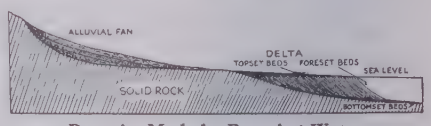
Other types of valleys are those which develop from the outflow of lakes; still others, which are formed as a result of the downfolding of rocks into structural depressions, are known as *structural valleys*. No matter how the valley has been formed, its size is somewhat limited by that of adjacent valleys. Some streams, however, are able to grow more rapidly than others, and thus they enlarge their drainage system by *capturing* parts of other rivers. Such streams are known as *pirates*.

The topography of an area being eroded is constantly changing. At first the running water roughens the surface by cutting out valleys, leaving ridges and hills between; but later the hills and ridges are reduced to the level of the valley bottoms. The plain which is approached before the hills are completely eroded is called a *peneplain*, and the elevations which rise above its general surface are known as *monadnocks*. When the latter have been completely subdued the resulting plain is called a *base level*. The time necessary to produce this condition is a *cycle of erosion*.

Just as the face of a man shows different and characteristic expressions in youth, maturity and old age, so do river valleys have diverse but easily recognizable physiographic expressions at different stages of their development. The cycle has its inception at the beginning of valley development, when drainage is in its *infancy*, and the infant valley is a ravine or gully. The valley becomes deeper, longer and somewhat widened, and passes into the *youthful* stage. In this stage of development the valleys are relatively deep, the divides between them relatively broad, and the streams are swift; they erode their bottoms rather than their sides, and their courses are marked by rapids and falls. As the valleys are deepened toward base level their power to cut vertically is greatly diminished; and they begin to widen their valleys and increase their number of tributaries. The country is reduced largely to slopes and only a little of the original upland surface remains. In this condition both the drainage and the topography are said to be *mature*. As the erosion processes are continued the gradient of all the valleys becomes less, the valleys grow wider, the hills and ridges are lowered, the divides become low and indistinct and the streams *meander* back and forth across swampy flood plains. Such valleys are described as *old*, and the country adjacent to their courses is also in topographic old age.

How the River Valley is Made

This diagram illustrates various stages in the development of river valleys. Valleys developed to stage *a* on the plain 1,000 feet above sea level are young; they are in late youth at stage *b*; early maturity at *c*; maturity at stage *d*; late maturity at *e*; early old age at stage *f*, and old age at stage *g*. They cannot cut much lower than *g* because the grade from *g* to sea level is needed to keep them flowing seaward.



Erosion is a group term applied to all processes by which soil or rock are loosened or carried from one place to another. The important subprocesses are weathering, transportation, corrasion and corrosion. *Weathering* is the term applied to all processes which loosen or change the exposed surface of rocks. *Transportation* is that process by which the products of weathering are moved. *Corrasion* is the mechanical wear effected by running water. *Corrosion* is the chemical effect of streams in dissolving soluble materials. These various processes are affected by the climate, by the gradient of the streams, by the physical and chemical character of the rocks over which the streams flow, and by the structure or attitude of the rocks.

Because of the various conditions affecting erosion many diverse surface forms result from stream action. Bad-land topography is developed in the early stages of maturity in high lands where the rocks are slightly and unequally resistant, and where the rainfall is limited to a few heavy showers during the year. Deep, narrow valleys most commonly result during the youthful stages of erosion of high, arid lands, and are called *canyons*. Small, narrow canyons, or their straight-walled, deeper portions are sometimes called *gorges*. Inequalities of hardness in the rocks of a stream valley result in *rapids* where the water flows very swiftly, or in *falls* where the water actually plunges over rock ledges. Similarly *rock terraces* occur along the side of a valley where hard layers of rock alternate with softer ones. In such cases the valley walls are steep at and below the hard rocks, and gently sloping where the softer beds occur. *Narrows*, or *water-gaps*, are notable constrictions of a stream's valley wall which occur where the stream crosses highly inclined beds of unequal hardness.

Many other topographic features result from the erosion of rocks of unequal hardness some distance from the stream course itself. *Plateaus* are relatively high-standing regions of considerable summit area. *Buttes* and *mesas* are smaller features of the same type, and *hogbacks* are linear ridges which result from the weathering of tilted layers of unequal hardness.

As stream courses develop from gullies to valleys they tend to become *adjusted* to the underlying rock structure. The processes of adjustment continue until the streams flow as much as possible on the weaker rocks, and consequently the more resistant strata tend to become *divides*. At base level, however, even the divides have been reduced. The old age streams meandering across base-leveled plains may be *rejuvenated* by the general uplift of the land. Because of the uplift, the stream's gradient is increased, it again assumes youthful features, and a new cycle of erosion is begun. If the stream is able to maintain its course in spite of the uplift the meanders become *incised* and the stream is said to be *antecedent*. New streams originating as a consequence of the uplift are defined as *consequent*. In some instances the river system may be depressed in relation to sea level and the lower course become *drowned*, as in the case of the Chesapeake Bay area. A stream may also be checked by an upwarping of strata across its course, in which case the river is said to be *ponded* above the point of uplift.

Constructive Work. Rivers, in carrying mud, sand and gravel to the sea in their constant attempt to degrade the land surface to base level, are often forced to drop their sediment upon the land, perhaps to carry it on again when conditions are more favorable to transportation. Water drops its load generally because its current has lost velocity. The deposition is sudden when the stream passes from a steep slope to a gentle one, or

Deposits Made by Running Water

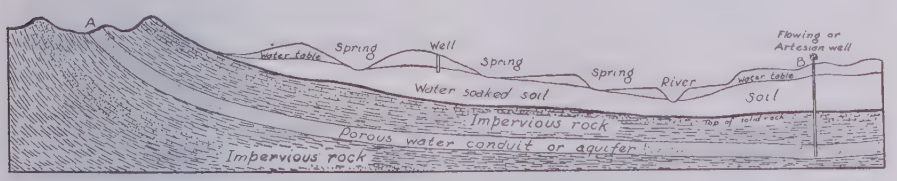


Diagram showing deposits made by running water upon the land and in the water. Note that the material of the fan is coarsest toward the source of supply. Note also that as the delta is built out to sea the landward portion becomes elevated.

when it flows into a body of standing water; it is slow when a stream gradient decreases gradually.

Deposition by running water takes place chiefly at bases of steep slopes, in valley bottoms and at river mouths. At the bases of steep slopes temporary streams are suddenly checked and deposit their heavy loads of debris in the form of partial cones, known as *alluvial cones*. *Alluvial fans* are similar deposits with lower angles of slope. The fans built by adjacent streams may spread laterally until they merge to form a *compound* alluvial fan, or *piedmont* alluvial plain. Such plains parallel the bases of most great mountain ranges.

As a stream descends its valley its gradient gradually is reduced, so that with diminished velocity it abandons part of its load. The sediment so deposited is left in the channel

of the stream at low water, but it is spread over the flood plains at high water, building them into alluvial plains. As streams grow older they tend to develop larger and larger alluvial plains. In times of flood the water, overflowing the normal channel, has its current checked as it moves out on the flood plain. For this reason sediment is deposited along the banks of the stream in the form of raised banks or *natural levees*. A stream in flood builds up its alluvial plain while eroding its channel, but when the water is low it again fills in its bed. This alternation of erosion and deposition in the stream bed is known as *scour-and-fill*. A stream with an alluvial plain generally meanders, that is, it has a very crooked, winding course. This is the result of low velocity, which permits the stream to be turned aside easily. The stream tends to cut its banks where they are least resistant, and once a curve of the bank is started it is increased by the current directed into it. As the current issues from this curve it is deflected so that it impinges against the opposite bank a little farther downstream. In this fashion a series of sinuous curves are developed so that the stream wriggles in snake-like fashion across its alluvial plain. In many cases the meanders become so pronounced that *moccasin bends* are formed. During flood stage the stream may cut off a meander and temporarily straighten its course. In such cases the abandoned channel becomes a crescent-like lake known as an *oxbow lake*. Lakes of this type are common along old streams such as the Mississippi and its larger tributaries.

Conditions Necessary for an Artesian Well

A cross section to show conditions required for artesian wells. Water enters the porous sandstone stratum at A and develops hydrostatic pressure which is released by the well drilled at B. The water table is shown in the soil above the bed rock.

At the point of debouchure of a stream into a lake or sea the velocity is promptly checked and its load is dropped. At such places, if strong waves or currents do not sweep the sediment away, *deltas* are formed. A delta has many features in common with an alluvial fan, but in the case of delta formation the current is checked more completely than in the building of a fan, and the initial deposition is beneath water rather than on the land. As the delta grows, however, it is built up to or even above the water level. Many large streams have built deltas of great size, of which those of the Mississippi, the Nile and the Hoang-Ho rivers are perhaps the best known. The united delta of the Ganges and the Brahmaputra has an area of 50,000 square miles above water, that of the relatively small river Po has been extended fourteen miles from Adria, which was formerly a seaport, and the Rhone River is adding about fifty feet a year to its delta front.

Work of Underground Water. Of the water which falls as rain or snow, one portion is carried to the sea by rivers, another portion is evaporated and goes back into the air, but a third portion sinks into the soil and the fractured bedrock beneath, and is known as *ground water*. This water fills the fissures in the rock and the pores of the soil up to a certain level whose surface is described as the *ground water table*. This table is lowered in dry weather and raised during the rainy season; it is near the surface in humid areas, and far beneath it in deserts. The surface of the ground water table in general conforms to the topographic irregularities of the land, but does not rise so high under hills nor fall so low under the valleys. Where the water table and the land surface intersect, springs, swamps, lakes or rivers occur. Wells also yield water because they have been dug deep enough to penetrate the water table. When they go dry the water table has been lowered below the bottom of the well.

Where water enters an inclined porous layer of rock which is enclosed between impervious layers, it may move down the slope, as in a conduit, until a considerable column of water is behind it, and great hydrostatic pressure is generated. Consequently wells drilled in such a position as to tap the porous layer give release to the pressure; and the water so obtained may be forced high in the air. Such flowing wells are called *artesian wells*.

Ground water takes substances into solution, transports them, and frequently deposits them; and thus it is an important geologic agent. Chemical denudation or the wearing away of land by solution is most effective in limestone areas, but is important in all humid regions. It is estimated that as a result of this type of erosion, or corrosion, North America supplies to the sea yearly 474,000,000 tons of material in solution.

In limestone areas the ground water enlarges natural fissures by solution until they become distinct underground channels. The latter further enlarge to form *caves* or *caverns*. The openings leading downward into these caves are termed *sink holes*. The underground waters may deposit some of the materials carried in solution on the roofs or floors of caves. Those icicle-like pendants which hang from the roof are known as *stalactites*, whereas those which grow upward from the floor are termed *stalagmites*. Deposition in caves commonly results in formations of grotesque form and bizarre beauty.

Work of Ice and Snow. *Non-Glacial ice.* The freezing of water in crevices of rock tends to disrupt the rock by ice wedge work, and the expansion of water in soil as it freezes also produces a variety of effects. On slopes it causes a slow downward *creep* of rocks and soil, and, together with the work of ground water, it is instrumental in moving masses of broken rocks in *landslides* and *rock glaciers*. In streams which freeze, the ice becomes cemented together with gravel and soil which are transported when the ice breaks up in the spring. The ice of lakes modifies their shores by the thrust which it exerts upon expansion. The ice which fits the lake perfectly when first frozen contracts under very low temperatures and cracks form. Water welling upward into the cracks is frozen and the ice again fits the lake. With return of warmer weather, however, the ice expands and exerts an enormous pressure. By this means loose material along the shore is pushed up into walls known as *ice ramparts*.

There are places on all continents except Australia where the annual fall of snow is not completely dispersed each year by evaporation and melting. These perpetual snow fields occur only on the tops of lofty mountains in the tropical zone; they occur on much lower mountains in the temperate zone, and in the arctic they approach sea level. Thus, from equator to poles there is a descending line above which snow lies all the year, and consequently this line is called the *snow line*. In the snow fields the snow becomes compacted by the weight of the various annual layers, and changes character. The snow is altered from its original loose, feathery condition to a coarse granular material known as *nevé*, which is partly the result of alternate freezing and thawing at the surface. The nevé passes downward into porous ice which becomes progressively denser with depth. If the nevé is followed down slope a point is reached where movement begins, and the ice in a sense slowly flows down the valley. At the place where this forward motion of the glacier is balanced by its melting there issues a river which carries off the water. The point where movement begins is commonly regarded as the beginning of the *glacier*.

Glacial Ice. The ice fields of the world are divided into three great classes: (1) valley, or Alpine, glaciers; (2) piedmont glaciers; and (3) continental glaciers, or ice caps. Valley glaciers are typical of all mountain regions which rise above the snowline. Like rivers they may have tributaries; all have catchment basins for gathering of the snow; all are confined to valleys, and all move down slope; and usually they are replaced by rivers at their lower ends. Valley glaciers are so common in the Alps that they sometimes are termed the "Alpine type."

When a number of valley glaciers descend out of the mountains on to nearly flat land they may give rise to a large body of nearly stagnant ice. Such ice fields, or piedmont glaciers, are confined to high latitudes, and are uncommon. Continental glaciers are ice sheets of vast extent. They may be regarded as "oceans" of ice when compared to the "rivers" and "lakes" of ice seen in the valley and piedmont glaciers. The present Greenland ice cap covers an area of about 700,000 square miles, and the Antarctic ice cap is nearly 5,000,000 square miles in extent. That other similar, but even greater, ice sheets existed in the geologic past is indicated by the record of the geologic work which they performed over much of northern North America and Europe.

A number of theories have been advanced to account for glacial motion, but the most probable explanation seems to be that by melting and refreezing under pressure, and

by movement along gliding planes in the ice itself, the granules change position, and thus the ice undergoes a slow flowage which imitates, but is not, a viscous motion. The surface of a glacier is traversed by wide, deep cracks known as *marginal*, *longitudinal* and *transverse crevasses*. It is also covered in places by heaps of earth and stone called *moraines*, which, according to the position they occupy, are known as *lateral*, *medial*, *ground* and *terminal*.

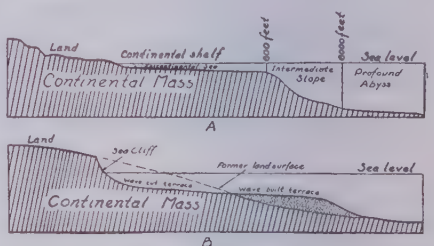
The glacier in its movement acts as a monstrous rasp, for frozen into its base are many boulders and sharp angular fragments of rock. These are its cutting tools, and they constantly grind away the bed rock on which it moves. This bed rock soon becomes smoothed and polished but marked also by grooves called *glacial striae*, which run in the direction of glacial movement. These and

At the Glacier's Edge

A diagram to show the deposition of material at the melting edge of a glacier. The ice front remains stationary when melting just balances the rate at which ice particles advance. Thus as the ice moves toward the right in the diagram, material frozen into the ice is brought to the melting edge and dropped there to form a terminal moraine. The water flowing away from the ice builds up an outwash plain.

other characteristic erosional features may remain after the glacier has melted away, and they attest to the fact that the area in which they are found has been *glaciated*.

Glaciers erode in their upper courses, whereas the material incorporated into the ice there is finally deposited at the point of their melting. Unlike water-laid sediments these deposits are unstratified. They are composed of a heterogeneous mixture of smoothed, striated and faceted boulders which have taken part in the erosion work of the glacier, and of those, which having ridden on the surface of the glacier, are still rough and angular. This morainic material, which is not only heterogeneous as to size of material, and degree of rounding or of faceting, but as to type of rock as well, is called *glacial till*, or *boulder clay*. Great blocks of rock, differing markedly in composition from the bedrock on which they rest, clearly have been transported by ice and are known as *glacial boulders*, or *erratics*. In many cases they are as large as a small house.



The deposits of a continental glacier are more extended than those of valley glaciers. They form well defined terminal and ground moraines, but no well marked lateral or medial deposits. The materials left behind after the melting of continental sheets are grouped under the term *glacial drift*. The drift may be characterized by narrow, rounded, elongate hills of unstratified material whose longer axes point in the direction of ice movement, known as *drumlins*; by *kames*, which are hills, knobs or short ridges made of stratified material lying athwart the direction of ice movement; by *eskers*, which are long sinuous ridges of stratified sands and gravels trending in the general direction of the ice flow; or by *valley trains* which represent the materials carried away from the ice front by streams generated by the melting ice.

Oceans. The oceans cover nearly three-fourths of the globe, and their average depth is about two and one-half miles. In spite of their great depth and tremendous extent, however, they are in reality a mere film on the face of the earth. If a sphere three feet in diameter representing the earth were dipped in water and withdrawn, the wet film adhering to its surface would correctly depict the oceanic depth. The oceans have overflowed the oceanic basins and have inundated the *continental shelves*. The parts of the ocean resting on these continental platforms are called *epicontinental seas*, and they have a total extent of about 10,000,000 square miles.

The ocean is not only an important regulator of climate, but it is also a geologic agent of the first rank. Its geologic work depends upon its movements which may be divided into three classes: *ocean currents*, *tides* and *waves*. The unequal heating of the ocean by the sun in tropical and polar regions establishes a slow general circulation of water by convection currents. This circulation is increased and modified by prevailing winds, and by the configuration of land and sea. The best known current is the Gulf Stream. The tide is a huge uplift, or wave, of the ocean caused by the attraction of the moon, and, to a lesser degree, of the sun. Were there no continents it should pass around the earth in about twenty-four hours, but the interval between tides is actually twelve hours and twenty-six minutes. This is the reason why the time of high and low tide progressively changes from day to day. The tide rises highest in narrow bays and estuaries where the difference between high and low tides may be as much as fifty feet. On exposed headlands the difference is commonly only a few feet, and the tides are not noticed on the open ocean. Waves are due to the force of the wind. The water particles move in circles and thus generate the wave form which advances, though the water itself ordinarily does not. On shores, however, there is insufficient water to complete the wave form and as a result the tops of waves collapse with a strong forward motion. This results in *breakers* or *surf*.

The surface of the ocean is an ever-moving, horizontal saw which is eternally cutting all shores. Sea water has a solvent action on most rocks, thus aiding the more important work of currents, tides and waves, which is largely mechanical. The chief eroding action results from grinding effected by dislodged sand, gravel and boulders which act as the tools of the moving water. In the erosive process the tools themselves are rounded and reduced in size. The resulting material is carried away from the shore line by *undertow*, and by tidal and shore currents; and thus it is prevented from serving as a buffer of loose material which would protect the shore. The effective erosion by waves is confined to a narrow zone. Where the sea is cutting its shore back into higher land, the seashore is marked by a cliff. Beneath the cliff is an area of shallow water which marks the lower limit of wave action, and is known as the "shore platform" or "wave-cut terrace." The terrace is slowly lowered seaward to a point where the depth prevents further erosion. Here the materials eroded from the shoreward edge of the platform accumulate and form deposits known as "wave-built terraces."

Shallow water deposits are confined to the continental shelfs. The *beach* is the familiar edge zone of seas which consists of material being worked over and ground up by the waves. The sediments of a beach commonly are coarsest at the landward edge and become finer toward the sea. If the continental shelf slopes very gradually breakers may form relatively far out to sea, and the waves in such cases pick up sediment from the bottom and move it shoreward. The undertow, however, tends to move the material back again, and hence there is built up a long, narrow bar parallel to the general trend of the coast. Such bars may grow until they are above sea level, and are known as *barriers*. Between the barrier and the mainland lies a body of water which is called a *lagoon* if small, or a *sound* if large. Shore currents commonly sweep materials across the mouths of indentations of the coast and build the sediment up in the form of an embankment which may eventually become land. Such embankments with free ends are called *spits*, whereas those which close or nearly close the indentation are known as *bars*. Tidal currents sweeping in and out of the *bay* behind the bar generally prevent complete closure by maintaining an *inlet*.

Shore Processes

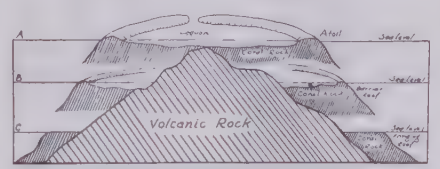
A. Diagram showing relation of continental mass to oceanic basin and epicontinental sea. B. Diagram representing the cliff resulting from the sea advancing on a greatly sloping coast. The material eroded from the cliff base is moved seaward and deposited on the outer edge of the wave-built terrace.

The rivers, bringing sediment to the sea, deposit it near their mouths where part of it is reworked and mixed with the material obtained by the erosion of the shore. It thus happens that the continental shelf is continually receiving sediments which are deposited in definite layers, or *stratified*. These sediments may have mixed with them the remains of plants and animals which lived in the shallow waters or were swept out to sea by the rivers. In general, the coarse-grained sediments are found near the coast, and finer and finer deposits farther out to sea. Thus sands and gravels commonly are being deposited near the shore, fine-grained muds farther out in quieter waters, and still farther seaward limy oozes are being laid down.

The ocean bottom beyond the edge of the continental shelf and down to a depth of 6,000 feet is called the *intermediate slope*. It may be considered as the side or wall of the true ocean basin. The deposits are chiefly the very finest of the land sediments or *blue* and *green* muds. The *profound abyss* comprises all the ocean bottom below the 6,000

feet line. Over most of this floor land derived sediments are wanting, but deep sea sounding has determined that it is covered with peculiar fine, soft deposits called *oozes*. These oozes are volcanic, organic or cosmic in origin.

Lakes and Interior Drainage. Lakes are enclosed bodies of water with little or no current. They are generally fresh but a few are salt. They have their origin in structural depressions, in rock basins which have been formed by glacial or volcanic action, or behind natural dams which have been formed across drainage channels. Glaciers are perhaps responsible for most lakes, as is indicated by the fact that lakes are far more numerous in glaciated than in unglaciated areas. From the geologic standpoint all lakes are only temporary. This is true because all rivers which feed lakes tend to fill them up with sediment, whereas all streams flowing out of lakes tend to deepen their channels upstream and thus in time completely drain the lakes.



Rivers which end not in the sea, but, through evaporation, in interior basins are called *interior drainages*. In such drainages the salts carried by the streams constantly accumulate at the point where drainage ends. This place may be called a *salina*, or salt marsh, if it is swampy, or a *salt lake* if it is a permanent body of water. Salinas are common in desert areas, and many examples of salt lakes such as the Dead Sea and Great Salt Lake, are known. Salinas and salt lakes are commonly important economically, for many valuable alkaline salts may be concentrated in them.

The erosive and depositional work of lakes is essentially similar to that of the ocean, previously described.

Geologic Work of Organisms. Animal and vegetable life is present over much of the surface of the land and throughout much of the sea. In many cases these organisms tend to destroy existing structures; in others they build new ones, and in still others they protect existing structures from the action of other agencies. The most important protective effect is that of vegetation in hindering erosion of the soil either by wind or running water.

Destructive Work. Vegetation acts in a mechanical way to destroy existing structures, as is seen in the splitting and disintegration of rocks by the roots of trees and other plants. The plants also play an important rôle in chemical weathering for they aid in the formation of the carbonic and humic acids which tend to reduce rocks to soil. Animals are less destructive than plants, but even such insignificant creatures as earthworms and ants aid the process of weathering by constructing holes and burrows and by bringing fresh material to the surface. The most destructive animal, however, probably is man, who by cutting down forests has greatly increased the rate of erosion over large areas, and who has by his great engineering projects even reversed entire drainage systems.

The constructive work of plants is best exemplified in the formation of peat bogs. *Peat* is brown to black carbonaceous material formed by the partial decay of vegetable material under a protective covering of water. In the growth of a plant the carbon dioxide of the air is decomposed, the carbon is utilized by the plant, and the oxygen largely returned to the atmosphere. In addition plants use the oxygen and hydrogen of water, and certain mineral compounds of the soil. Their framework, however, is largely cellulose, $C_6H_{10}O_5$, which for simplicity we may regard as forming the organic matter of plants. If cellulose is burned in air complete oxidation takes place with the formation of carbon dioxide and water vapor. If the air supply is limited, as it is in burning wood in kilns, the oxidation is incomplete, and a greater part of the carbon remains behind as *charcoal*. Similar though much slower processes take place in nature. The woody material of dead plants slowly oxidizes or decays and the component parts are returned to the air and soil. If the decay takes place under water, however, as it does when plants grow in water, or fall into it after death, the oxidation is incomplete. In this case the partly decayed material is rich in carbon, and forms the carbonaceous substance described above as peat.

Formation of Reefs and Atolls

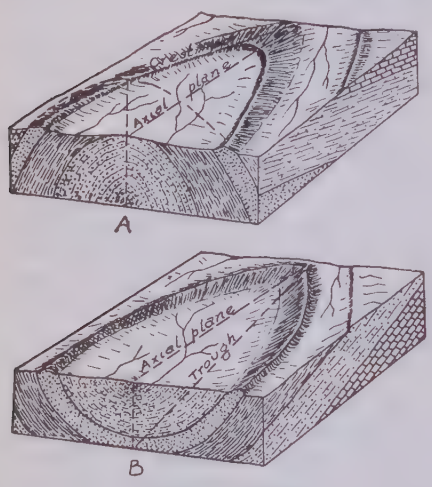
Sections showing the successive formation of a fringing reef, a barrier reef and an atoll during the relative elevation of sea level from C through B to A.

Peat is forming today, just as it has through the long geologic past, in small lakes, ponds, lagoons and marine marshes. Peat is the first stage in the formation of coal, which results from the slow compacting of the peat, not only as a result of the weight of sediment put down over the organic material, but also as a result of slow chemical processes. These *dynamo-chemical* processes result from deep burial and great pressures operating over long periods. They cause the further oxidization or escape of gases from the organic material and leave the residue richer and richer in carbon.

The constructive work of animals has resulted in enormous deposits. Most of these have been built by marine organisms which extract calcium carbonate from the water in which they live, and build their skeletons of it.

Of all these animals the corals are perhaps the most interesting. The corals are lowly marine animals which secrete a stony base of calcium carbonate to support their filmy bodies. Although very small, they live together in colonies made up of countless individuals. The most important of the corals, geologically speaking, are the *reef-builders*. This type is common today in warm, clear, shallow seas, and they were abundant in the past apparently in a similar habitat.

Corals grow upward and spread laterally as one generation builds upon the bases of their dead ancestors. Many other animals living among the corals also have their skeletons incorporated into the constantly accumulating material. Calcium carbonate, deposited out of the warm sea water, cements the fragments together and eventually the deposit becomes a solid white limestone upon whose upper surface the corals flourish. This surface rises until it is just below the level of low tide, and forms the *coral reef*. These reefs include the fringing reefs, barrier reefs and atolls.



Corals growing in shallow water at the edge of existing land gradually build up a platform to sea level, which, since it fringes the older land, is called a *fringing reef*. *Barrier reefs* are similar to the fringing type but are located some distance from the land, and are separated from it by a lagoon of varying width. These lagoons commonly serve as good harbors, though in many cases they are too shallow for large ships. *Atolls*, like many barriers, are more or less circular, ring-like reefs, but they are without any central land mass, and they inclose a shallow lagoon. Many reefs of the latter type apparently have been formed by the subsidence of the volcanic island around whose shore they originated. Chalk, limestone, coquina and phosphate rock also are in large part of organic origin.

Materials of the Earth's Crust. When carried by any transporting agent rock waste becomes *sediment*. Most of the transporting agents, except ice, have the power of *sorting* this sediment because changes in the velocity of the agent are directly reflected in its ability to move various types of material. It thus happens that two layers of material may be separated by a distinct juncture plane, known as the *bedding plane*, on either side of which they differ in texture or composition. Such bedding is called *stratification;* the rocks so bedded are said to be *stratified*, and they generally are of the *sedimentary* type.

The most common sediments are gravel, sand and mud. These may be deposited upon the land, in which case they are *continental;* they may be deposited on the beach and are then called *littoral;* or they may fall to the ocean floor beyond the strand line, in which case they are said to be *marine*. After the sediment is laid down it generally is cemented into solid rock by the deposition of mineral matter held in solution in water. The cemented gravel is called *conglomerate* if the fragments are rounded, *breccia* if they are angular; the cemented sand is called *sandstone;* and cemented mud is known as *shale*. These are common sedimentary rocks, and they are said to be *clastic* (fragmentary) since they are made of particles derived from other rocks. Some limestone, which is broken up, redeposited and recemented, is also clastic. Many sedimentary rocks are not clastic. Some, including most limestones, are formed either by chemical precipitation, or more commonly by the cementation of organic remains. Some, such as salt and gypsum, are entirely the result of precipitation from saturated solutions. The principal classes of sedimentary rocks are given below:

Clastic	Mechanically formed....	Conglomerates — gravel, conglomerates, breccia
		Arenaceous rocks—sand, sandstone, arkose
		Argillaceous rocks—clay, shale
		Some limestones
Non-clastic		Some carbonate rocks—some limestones, travertine, siderite
	Chemically formed....	Chlorite rocks—rock salt
		Sulphate rocks—gypsum
		Some siliceous rocks—some flint, some chert
	Organically formed....	Calcareous rock—many limestones
		Carbonaceous rocks—coal, peat
		Siliceous rocks—siliceous oozes

Most sedimentary rocks are stratified, but some, such as glacial till and some conglomerates, are not. If bedded, the term *stratum* is commonly applied to a single layer, and *formation* to a set of layers, or strata, of similar nature and considerable extent. Sedimentary rocks, especially shales, are in many cases very thinly bedded and are said to be *laminated.* Many of these sedimentary rocks are marked by *cross bedding, mud cracks, ripple marks* and *raindrop impressions,* just as sediments deposited today are so marked. Many of the rocks of the earth have had their original positions altered by crustal movements, but these alterations are recorded best in sedimentary rocks since they are definitely layered. The *dip* of a rock stratum is its inclination when referred to a horizontal plane, whereas its *strike* is the trend or direction of its horizontal edge. Where beds dip

Results of Erosion

A. Block diagram to show features resulting from erosion of a symmetrical anticline. B. Block diagram to show features resulting from the erosion of a symmetrical syncline.

in a single direction they form a *monocline.* Where they are arched upward into a fold, they form an *anticline,* and where downfolded they form a *syncline.* Where found in nature many folds are rather completely eroded, but their character may still be determined by a study of their dips and strikes.

Sedimentary rocks are spread over a large part of the earth's surface, but their thickness, though locally measurable in thousands of feet, is relatively slight; and they may be thought of as constituting a veneer over the igneous or metamorphic rocks on which they rest.

Igneous rocks are the products of vulcanism. Because of the tendency of various types to intergrade they are difficult to classify, but on the basis of chemical composition they may be divided into *acid* and *basic* rocks. The acid rocks are rich in silica, and poor in iron, lime and magnesia. They are generally light in color, fuse only at high temperatures, and have a relatively low specific gravity. The basic rocks are relatively poor in silica, and rich in lime, iron and magnesia. They are dark in color, fuse at relatively low temperatures, and are heavier than the acid types.

The rate of cooling also influences the character of igneous rocks. Those that cool slowly so that crystals have a chance to form are coarse-grained; those that cool more rapidly are fine-grained, or in extreme cases, glassy; and some are fragmental. The coarse-grained rocks are all intrusive in character, that is, they cooled deep within the earth; where they are now exposed erosion has removed the rocks into which they were intruded. *Granite* is one of the most abundant rocks of this type. It is made up of the minerals *quartz* and *feldspar,* usually with minor amounts of *mica* and *hornblende.* (See section on "Mineralogy.") *Syenite* is a rock similar in every respect to granite except that it contains no quartz. *Diorite* is a coarse-grained rock composed largely of hornblende and feldspar. *Gabbro* is superficially similar to diorite, but in it the hornblende is replaced by *augite. Peridotite* is composed entirely of ferro-magnesian minerals, such as hornblende, augite and *olivine,* and it lacks feldspar. Peridotites are of special interest as they are the only rocks in which diamonds are formed.

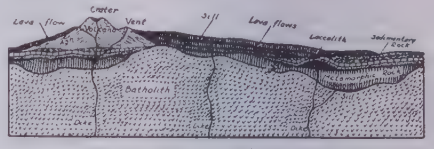
The fine-grained igneous rocks were extruded onto the surface so that they congealed before any considerable crystal growth. *Felsites* are the light-colored, fine-grained chemical equivalents of the coarse-grained granites and syenites. *Andesites* are rocks transitional in character between the felsites and the *basalts.* Basalts, or *traps,* are dark-colored, fine-grained, basic, extrusive rocks similar in mineral composition to the diorities and gabbros. The glassy rocks are *obsidian* and *pitchstone.* Obsidian is a natural glass which breaks with the same shelly fracture as artificial glass. It has a high luster, and is usually jet black, but it may be brown, red, green or gray. Pitchstone is similar to obsidian, but has a duller, more pitch-like luster.

The fragmental rocks are products of eruptions of explosives violence. *Tuff* is a light colored, highly porous rock made up of volcanic dust and ash. Volcanic *breccia* is a coarser igneous rock composed of angular fragments cemented together in a tuff-like matrix of ash and dust. Fragmental and fine-grained igneous rocks may have a rude to fairly perfect stratification, but in the main igneous rocks are homogeneous in character. For this reason their deformation is not so readily deciphered as that of the sedimentary rocks.

Metamorphic rocks are the products formed when igneous or sedimentary rocks are subjected to great heat and pressure. Metamorphic rocks which are massive, and homogeneous in size and arrangement of parts are said to be *nonfoliate;* those which have the mineral particles arranged so that the rocks readily split along definite cleavage planes are said to be *foliate. Marble* and *quartzite* are the chief nonfoliate metamorphic rocks. Marble is metamorphosed limestone. It is more coarsely crystalline than limestone and takes a high polish. For this reason it is widely used as an ornamental stone. Quartzite is metamorphosed sandstone in which the individual sand grains are so thoroughly cemented by silica that the rock breaks through the grains rather than around them.

Slate is one of the most common of the foliate rocks; it is metamorphosed shale. *Gneiss* is a coarsely foliated or laminated rock which resembles granite in composition, and which is usually marked by bands of segregated light and dark minerals. *Schists* grade into gneisses, but are typically more finely foliated. The results of the metamorphism of various rocks is shown in the following tables:

METAMORPHISM OF SEDIMENTARY ROCKS



Original Rock	*Metamorphic Equivalents*
Conglomerate	Gneiss and schist
Sandstone	Quartzite and schist
Shale	Slate and schist
Limestone	Marble

METAMORPHISM OF IGNEOUS ROCKS

Original Rock	*Metamorphic Equivalents*
Coarse-grained acid rocks (Granite and syenite)	Gneiss and (rarely) schist
Fine-grained acid rocks (Felsite, tuff and others)	Gneiss, schist and slate
Basic rocks (Diorite, gabbro, basalt and others)	Schist

Vulcanism. Vulcanism is the term applied to all movements of molten rock toward the surface of the earth, as well as to certain related phenomena. The molten rock which reaches the surface is known as *volcanic,* and is said to be *extrusive;* that which congeals before reaching the surface is known as *plutonic,* and is said to be *intrusive.*

Molten rock which solidifies in fissures forms *dikes;* in chimney-like openings it forms *pipes* or *plugs;* inserted between layers of rock it forms *sills,* and where it arches the strata above it forms *laccoliths.* Still more massive instrusions are known as *batholiths.* All of these intrusive bodies bake or *metamorphose* the rock into which they are intruded, but thin dikes and sills produce no great effect.

Types of Igneous Formations

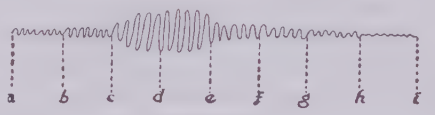
This diagram shows various types of extrusive and intrusive igneous bodies.

The extrusive processes are the most impressive of geologic phenomena. Volcanoes are elevations built of the igneous material thrown out of a central vent. In its most typical form a volcano is a steep, conical mountain with a pit-like depression, or *crater,* at its top, from which there issues at times of *eruption* gases, ashes, steam, bombs and flows of molten rock called lava. Many volcanoes, however, are low, some are irregular in shape, and in others the crater may be located far from the center; some are not over 100 feet in height, and yet others attain an elevation of more than 20,000 feet. We may classify volcanic eruptions as those which are *explosive* in character, those which are *quiet,* and those which are of the *intermediate* type.

Volcanoes of the explosive type give rise to sudden, violent explosions during which great quantities of gas, dust and ashes are shot high in the air. During the eruption of Krakatoa, more than four cubic miles of material were blown into the air; the vast cloud so formed completely hid the sun over many thousands of square miles; the terrific

detonation was heard for more than 150 miles, and more than 40,000 natives of Java and Sumatra were drowned by the great waves generated by the explosion. The volcanoes of Mont Pelée and Soufrière in the West Indies, and Mt. Katmai in Alaska are of the same type. Many explosive eruptions apparently are so violent that they destroy the volcanic cone, and leave in its place gigantic basins called *caldera*. Crater Lake, Oregon, occupies such a depression, but in this particular case the former volcano seems to have collapsed rather than exploded.

Quiet volcanoes give rise to outflows of liquid lava without the issuance of ashes, or the violent expulsion of gases. The Hawaiian volcanoes are the best examples of this type, and the Hawaiian Islands have been built up 30,000 feet above the sea floor as a result of the long continued eruptions of this type.



In the intermediate type of volcano the eruption begins with explosive violence, but in its later stages it produces great lava flows of a more or less quiet nature. Vesuvius, the recently extinct cones of the Pacific northwest, such as Mt. Rainier and Mt. Shasta, those of the Aleutian Islands, and, in fact, most volcanoes are of this character.

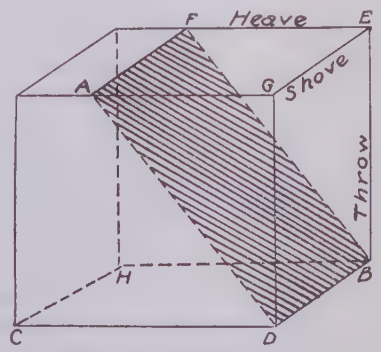
Long after an eruption has taken place, vapor and gas may escape from minor vents in the crater or on flanks of the volcano in emanations known as *fumaroles*. Where these vapors move through layers of sediment they may form small cones of mud with miniature craters termed *mud volcanoes*. *Hot springs* are also common phenomena which are caused by ground water coming in contact with hot rocks deep beneath the surface. *Geysers* are gushing hot springs whose eruptions are due to the accumulation of water under pressure which is heated above the boiling point. Steam forming at the bottom of the ground water conduit forces water out at the top, or crater, of the geyser. This relieves the pressure throughout the conduit with a result that a great deal of the water immediately turns to steam and is ejected violently.

For the causes of vulcanism the reader is referred to one of the standard reference works listed on page 976.

Diastrophism. The outer shell of the earth is not fixed and rigid, but it is constantly oscillating, as can be shown by comparing the land elevation with that of the sea. Along certain coasts it is common to see features made by the work of the waves now elevated far above their reach. Along other shores the physiographic features, such as drowned valleys, submerged forests and the seaward extension of river channels, indicate clearly that the land has been depressed in relation to sea level. All such movements of the outer shell, whether of continental masses, or of mountain making type, whether of folding or fracturing or of thrusting or stretching, are included under the group term, *diastrophism*. The immediate cause of the movements of the earth's crust is the unequal contraction or shrinkage of the earth as a whole. A discussion of the ultimate causes of diastrophism does not lie within the scope of this volume.

The earth's shell is constantly undergoing movements, some of which act through long periods of time, others of which take place rather suddenly. Those of the latter type sometimes occur as recognizable tremors which are called *earthquakes*. The study of earthquakes is known as *seismology*, the instrument which records them is called a *seismograph*, and the record written by the stylus of such a machine is a *seismogram*. The principle upon which a seismograph is constructed is that a heavy pendulum, owing to its inertia, will remain at rest when an earthquake shock vibrates the earth beneath it. A stylus is attached to the suspended weight or pendulum, and a strip of paper revolving on a drum operated by clockwork is fixed to a pile driven to the solid rock. The stylus draws a straight line on the paper while it is at rest, but a vibration of the pile causes the line to oscillate sinuously from one side to another. The study of seismograms has shown that the main shock of distant earthquakes is preceded by smaller quick vi-

Seismogram



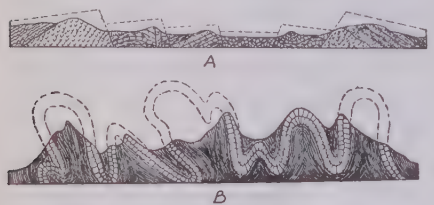
A distant earthquake seismogram: *ab*, first preliminary tremors; *bc*, second tremors; *ce*, main tremors; *eh*, later phases; *hi*, tail.

brations. These tremors represent the shock which has come through the earth, that is, along a chord; whereas the large vibrations represent the waves which have traveled the longer route along the surface of the earth. As the time between the arrival of the preliminary tremors and the main shock is proportional to the distance to the earthquake center, the distance to that place may be calculated at any seismograph station as soon as the record is received. If the distances from three recording stations are known the exact place of disturbance also can be calculated geometrically.

The rocks of the outer shell of the earth are traversed in all directions by fractures which vary from minute crevices to large fissures. Those fractures which develop in single rock masses are commonly known as *joints*, whereas those which traverse many adjoining rock masses are termed *rifts*. There are many kinds of joints and fractures and they occur in all types of rock. Movements along rifts either at the time of their formation or later may displace rocks with reference to their former position. Such displacements are called *faults*, and earthquakes commonly result from their formation. The fracture along which movement takes place is called the *fault plane*, or better, the *fault surface*, for it is rarely a plane surface. The movement in faulting may involve a series of blocks in which case a fault *zone* is formed, and the process is called *step faulting*. The rock masses involved in faulting exert great pressure on the faulting surface, and the rock faces, therefore, commonly exhibit polishings and groovings known as *slickensides*. The line of intersection of the fault with the horizon is known as its *strike* (trend), whereas the angle of the fault surface with the plane of the horizon is known as its *dip*, and the angle formed with the vertical plane is termed the *hade*. In the case of an inclined fault the upper side is known as the *hanging wall*, the lower as the *foot wall*.

Faults in which the movement has been such that the hanging wall has moved down with respect to the foot wall are known as *normal;* those in which the hanging wall has been shoved up over the foot wall are described as *reverse*. With reference to their supposed mode of origin, reverse faults are sometimes termed *compression* faults, and normal ones *tension* faults. Faults are among the most common of geologic phenomena, and in many cases they are of great economic importance for they serve as the place of deposition of many great ore bodies. As a result of their formation many topographic features such as *fault scarps* and *block mountains* arise. Many normal faults have *displacements*, or movements along the fault surface, which are to be measured in thousands of feet, and in some reverse, or thrust, faults the hanging wall has ridden over the foot wall for distances of several miles.

A *mountain* is a conspicuous elevation with a limited summit area. There is great local variation in the usage of the term mountain, for many small hills are given the distinction of that name, whereas the Black Hills of South Dakota are truly great mountains, though not designated as such. Mountains may be irregularly disposed in *groups* such as the Catskills, or aligned as *ranges* such as is the case of the Sierra Nevadas. Ranges may consist of a single ridge, but in most



Fault Diagram

Diagram illustrating the various components of normal faults. The fault surface is shaded, the bars indicating the direction of movement. AB is the displacement if a point formerly at A has moved to B.

cases they are compound, that is, composed of many ridges whose general direction is parallel. A range is regarded as a *geologic unit* since it was formed at a definite time by a definite set of processes. A group of ranges having a common general trend, and formed at about the same time, is known as a *mountain system*, whereas a complex combination of systems, such as those of the Andes, constitutes a *cordillera*.

Many mountains are formed by igneous agencies. These are mountains produced by the extrusion of igneous materials to form volcanic peaks, and elevations formed by the intrusion of igneous material into sedimentary rocks, which are domed and elevated by the process. Some mountains are formed by the erosion of elevated tracts of land leaving isolated remnants of the former plateau surface. Many of the western buttes are

mountains of this type, as are the Catskills of New York. The above mountain types, however, are of small importance when compared with those which have been formed by movements of the earth's crust. Such mountains may be made chiefly, or entirely, by faulting, or they may be produced by wrinkling or folding. In the former case, the ranges are the exposed edges of great tilted blocks of the earth's crust, consequently they are called *block mountains*. The Great Basin ranges of Nevada are of this type. In the second case the ranges result from the wrinkling of the crust into anticlines and synclines, and are called *folded* ranges. Most great mountain ranges are of the latter type,

Mountain Structures

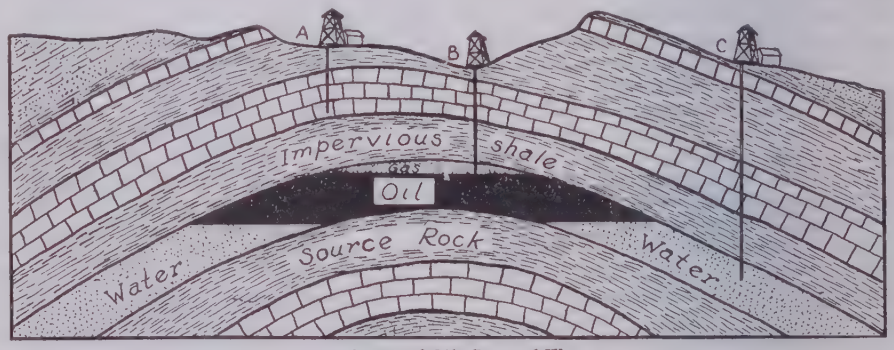
A. Faulted mountain structure, Great Basin type. Dotted lines indicate the position of the blocks unmodified by erosion.

B. Folded mountain structure, Alpine type. Dotted lines represent the shape of the uneroded folds.

although most of them are also rather complexly faulted as well as folded.

Detailed examination of folded mountain ranges has shown that they are invariably composed of masses of very thick sedimentary beds. These were deposited in a long basin of deposition or trough known as a *geosyncline*. As sediments were added to the basin it slowly sank, so that great thicknesses of sedimentary rocks resulted. After this long quiet pre-mountain forming period, the sediments of the geosyncline were thrown into complex folds by lateral pressures generated by the contraction of the earth's shell. Since the rocks are complexly folded, the areas in which they are located has suffered crustal shortening. In the Appalachians this crustal contraction amounts to at least fifty miles. That mountains have been formed after the manner described above is clearly indicated not only by field evidence, but by experimentations in which perfect replicas of existing mountain ranges have been made experimentally.

Some folded mountain ranges are particularly complex because igneous episodes occured in the late stages of their folding; and the study of all ranges is complicated by the effect of erosion on the folds.



Economic Geology. Compared with the great bulk of rock in the earth's crust, deposits of economic value are extremely rare, and where they occur they have been concentrated under unusual geologic conditions. It is the business of the economic geologist to search out such deposits and to aid in their exploitation. The materials of the earth which man utilizes may be divided conveniently into *non-metallic* and *metallic* substances.

The most important non-metallic mineral deposits are coal and petroleum. *Coal* is a sedimentary rock which is not difficult to locate, but whose profitable mining in many places is impossible. The geologist, by his knowledge of sedimentary processes, is able to increase the efficiency of mining in areas of normally profitable mines, and to introduce mining methods which make possible the recovery of coal in areas where ordinarily it would not be exploited.

Petroleum is quite as valuable as coal to our present industrial development, and its discovery falls particularly within the sphere of the geologist. Petroleum is a liquid hydrocarbon which is found in porous rocks such as sandstones. It apparently is entrapped during the deposition of marine shales, migrates from them into porous reservoir rocks, and finally is concentrated on or near the crests of anticlines. It is the business of the petroleum geologist to locate such structures, for although not all anticlines produce oil, nearly all oil is produced from anticlinal or similar upfolded structures.

Other valuable non-metallic products are *salt, gypsum, graphite, barite, mica* and *phosphates*. In addition to these, building stones, clays, limestones for the manufacture of cement, slate for roofing, and other similar products of the earth's more common constituents are, in the aggregate, of great economic importance.

Most of the valuable minerals are metallic; where they occur in quantities great enough to be mined profitably they are called *ores*. The study of these ores and their occurrence is one of the largest divisions of the subject of geology, but it can only be mentioned here. *Iron* is the most widely used of our metals. Together with petroleum and coal it forms the very basis of modern industrialism. Most of the great iron ore deposits are of sedimentary origin, and in most places they are mined by steam shovels. Most of the other ores are thought to have been deposited from hot solutions ascending through fissures of the earth's crust from some deep seated igneous source. In this category are most of the ores of *copper, gold, silver, lead, zinc, cobalt, nickel, antimony, arsenic, tin, aluminum* and *mercury*, though some of these also have had a sedimentary origin.

Accumulation of Oil, Gas and Water

Diagram showing the accumulation of oil, gas and water on the crest of an anticline. Well A has not been drilled deep enough to strike oil; Well B obtained both oil and gas, and Well C has encountered only water. The water moves upward in the porous sandstone and the gas is placed under great pressure, which, when released, causes flowing wells or "gushers."

HISTORICAL GEOLOGY

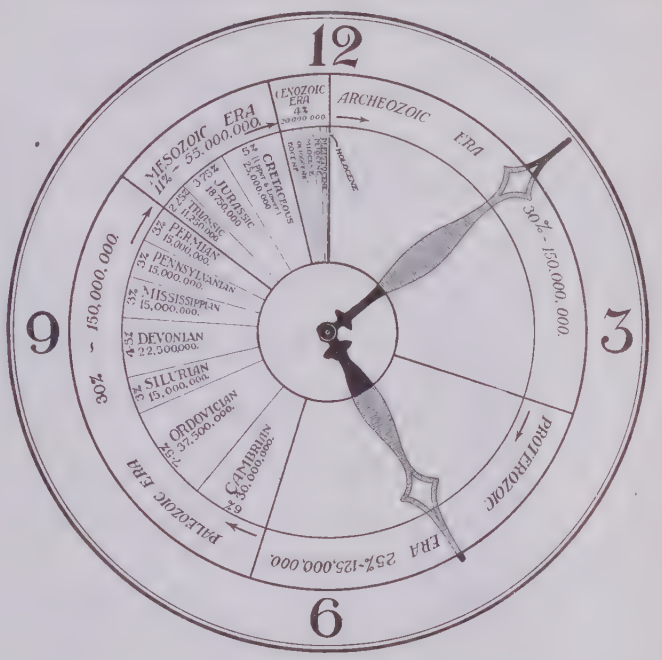
The Origin of the Earth. The stratified rocks of the earth's crust record its relatively recent geologic history with great fidelity, but the older events are in some cases indistinct, and the geologist has been unable to decipher all of the very earliest records. The complexly altered igneous and metamorphic rocks below the sedimentary veneer, and the inaccessible interior of the earth itself undoubtedly hold the secret of the earth's origin, but their study is difficult and has so far yielded only hints as to the final solution of the question. For this reason the relationship of the earth to other heavenly bodies has also been carefully studied in this connection, and as a result other suggestions as to the earliest stages of earth history have been obtained. Consequently a number of theories for the origin of the earth have been proposed, of which the planetesimal theory of Chamberlin and Moulton, of the University of Chicago, perhaps is the most widely accepted.

The planetesimal theory states that the sun, while in an early gaseous condition, was approached by another and probably greater star. The mutual gravitational attraction resulting partially disrupted the sun. The matter ejected from it took on the shape of long spiral arms connected with the central sun, whose mass was many times that of all the material in the arms. In this stage of the development of the *nebula*, our ancestral solar system resembled closely the *spiral nebulae* which may be seen in the heavens at present. The ejected material was mainly dust-like, small particles which have been called *planetesimals;* hence the name of the theory. Included in the cold dust-like material were a number of relatively large, possibly hot, masses called *knots*. These *knots*, in revolving in their orbits, were able because of their superior size, to gather the planetesimals to them to build up at last the nine planets, their satellites and the asteroids.

Changes of the Earth's Facial Expression. Whatever the origin of the earth, the keynote of all of its physical and organic history is change. The lands have altered slowly but continually. Mountains have been elevated to alpine grandeur only to be eroded to sea-level. The ocean has flooded the land, not once, but scores of times; and each inundation has left the record of its existence in the sedimentary deposits which it left behind.

"There rolls the deep where grew the tree,
O earth, what changes hast thou seen!
There where the long street roars hath been
The stillness of the central sea."

This is not only poetry, but sound geology. The area of Riverside Drive in New York, Michigan Avenue in Chicago, the Strand in London, and the Champs Elysees in Paris have all been beneath "the central sea" at repeated intervals. Even the continents themselves have changed remarkably in outline during the geologic past. Old Mother Earth has indeed suffered many vicissitudes; her facial expression changes daily, and though the changes are ordinarily too slight to be noted by the casual observer, the geologist knows that during the long geologic past her face has been wrinkled where now it is smooth, and unmarked where now it is deeply furrowed.



Fossils and Their Significance. A *fossil* is any record of prehistoric life. The rocks which contain them are the graveyards of the animals and plants which link the past with the present. Fossils vary greatly in their perfection. Insects are so perfectly preserved in amber that their soft parts may be dissected, and the extinct mammoths of the frozen Siberian tundras are so well preserved that even the contents of their stomachs ordinarily may be examined. Most fossils, however, are only parts of once living things.

Most dead organisms are at once attacked by microscopic fungi and bacteria, and by scavenging animals, so that they leave no trace of their former existence. If, however, the organism is covered by sediment immediately after death, a complete or partial record of its presence may be preserved. Organisms with hard parts have the best chance of writing their record into the rocks, but even most of these are not preserved. Fossils are of many different types. The soft parts in rare cases are preserved, but generally only the hard structures such as bones or shells remain. The latter may be preserved as the original material, but much more commonly these hard parts have been altered, or *mineralized*. In still other types of fossils the original substance is entirely missing, but the former presence of the organism is indicated by *molds*, *imprints* or *natural casts*.

Fossils are not freaks of nature, nor chance records of extinct organisms, but they are the very important documents upon which the time-table of the geologic past has been established. They also indicate the path of organic evolution, the ancient distributions and migrations of plants and animals, the habitats of these organisms, and they even give important information as to the changes of climate throughout geologic time.

The Geological Time-Table and the Age of the Earth. Geologic history, like human history, falls into certain major divisions, and these in turn into minor ones. The sequence of events is determined by the actual order of superposed sequence of stratified rocks, by the degree of evolution attained by the fossils found in the rocks, by the breaks, or *unconformities*, in the sequence of rock formations, and through the order in which igneous rocks intersect one another and sedimentary beds. The *era* is the longest division of geologic time; it is one volume of historical geology. The eras are divided into *periods*, which are chapters in the geologic volumes. Periods are sometimes further divided into *epochs*.

Man has long been interested in determining the age of the earth. Hutton, in 1795, after studying the geology of Scotland, said that he could find "no vestige of a beginning —no prospect of an end." Since that time the age of the earth has been variously estimated as from 20,000,000 to 1,600,000,000 years. The great differences in these estimates result from the different bases used in making them. The physicist's study of radioactivity results in the larger figure given above, whereas geologic evidence obtained through calculations of the time involved in the accumulation of salt in the sea, or in the deposition of the combined column of sedimentary rocks, gives a figure nearer 500,000,000 years. If the latter figure is taken as representing approximately the age of the earth since the beginning of the *Archeozoic*, or first era, and if all subsequent geologic time be shown as taking place during the course of an hour, the proper time relationships of the various eras and periods may be shown on the face of a clock, as is done in the accompanying figure.

Geologic Time Clock

If all geologic time since the beginning of the Archeozoic era is taken as 500,000,000 years and is represented on the clock as one hour, then thirty-three minutes of that hour elapse before the rocks begin to yield abundant evidence of life. The beginning of the Mesozoic era and the dominance of reptiles occur only nine minutes before the end of the hour. The Cenozoic era, or the age of mammals, lasted only two minutes and twenty-four seconds. And man, commonly stated to have been present for about 1,000,000 years, has occupied the center of the stage in the pageantry of changing life for only seven seconds of that hour.

Man makes iron implements 1350 to 900 B.C.
Man makes bronze implements 3500 to 2000 B.C.
Man makes polished (Neolithic) implements 18000 to 7500 B.C.

SYNOPSIS OF MAJOR EVENTS OF HISTORICAL GEOLOGY

Era	Period	Important Physical Events	Important Organic Events
Cenozoic	*Holocene (Recent)*	Completion of oceanic depression to present level. Climate as today. Gradual rise of depressed lands and depression of marginal bulge. Ocean waters flooding depressed lands.	
	Pleistocene	Ice front retreated to southern Sweden. Würm (Wisconsin) glacial advance. Interglacial period. Riss (Illinoian) glacial advance. Interglacial period. Mindel (Kansan) glacial advance. Interglacial period. Günz (Nebraskan) glacial advance.	Cro-Magnon Man—first of present species. Neanderthal man—Paleolithic culture. Heidelberg man—Paleolithic culture.
	Pliocene	Continued world-wide elevation. Epicontinental seas restricted.	Intermigration of North and South American mammals. Horses and elephants become essentially modern in appearance.

SYNOPSIS OF MAJOR EVENTS OF HISTORICAL GEOLOGY—Continued

Era	Period	Important Physical Events	Important Organic Events
Cenozoic	*Miocene*	World-wide uplift and mountain-building. Birth of Alps, Himalayas and other systems. Vulcanism in western North America. Marginal seas and cool climate.	Notable advances in the horse and elephant families. Apes appear in the Old World.
	Oligocene	Extensive erosion. Marginal seas. Warm climate.	Carnivores and ungulates become well established. First ancestral elephants.
	Eocene	Uplift in western North America. Marginal seas. Enlargement of Mediterranean basin.	Dawn of mammalian dominance. Reptiles in subordinate position. Coming of modern types of marine invertebrates.
Mesozoic	*Upper Cretaceous*	World-wide continental uplift. Birth of Rockies and Andes. Widespread interior seas. Formation of chalk and coal deposits.	Extinction of all Mesozoic types of reptiles and birds. Climax of cephalopods. Armored and horned dinosaurs reach climax just before extinction.
	Lower Cretaceous (Comanchean)	Great swamp deposits in North America. Some marine flooding in form of interior seas.	Introduction of modern flowering plants. Toothed birds and flying reptiles known. Marine pelecypods very abundant.
	Jurassic	Widespread emergence and erosion of North America. Small interior seas in northwestern North America. Birth of Sierra Nevadas.	First birds appear. Crustaceans take on modern aspect. Cephalopods very numerous. Gigantic reptiles common. Marine and flying reptiles abundant.
	Triassic	Continental and marine deposits in Europe. Mostly continental in North America. Widespread deserts with salt, gypsum and red beds.	Appearance of mammals. Reptiles dominate. Cycads prominent. Marine invertebrates reduced in number.
Paleozoic	*Permian*	World-wide uplift and mountain building, glacial episodes and aridity. Birth of the Appalachian system.	Extinction of most Paleozoic types of invertebrates and many Paleozoic plants. Reduction in all types of life. Primitive reptiles fairly numerous locally.
	Pennsylvanian	Crustal instability. Much land oscillating near sea level. Formation of world's greatest coal deposits.	Great coal forming forests. Earliest known reptiles. Trilobites become rare. Brachiopods, pelecypods and gastropods common.
	Mississippian	Coal swamps in Europe. Low lands and warm, mostly clear interior seas in North America.	Great abundance of crinoids. Sharks numerous. Amphibians become well established.
	Devonian	Progressive widespread submergence of continents. Terrestrial deposits in Europe and North America. Local diastrophism and vulcanism at close.	First amphibian record. Armored fish numerous. Brachiopods reach climax. First forests known. Coral reefs important.
	Silurian	Important marine transgression. Salt and gypsum deposits and aridity. Crustal disturbances in many parts of the world at close.	First air breathers in the form of scorpions. First great abundance of corals and coral reefs. Eurypterids reach climax. Trilobites diversified. Land floras appear.
	Ordovician	Three cycles of marine inundation in North America. Greatest known submergence. Vulcanism in British Isles. Local diastrophism in North America.	First vertebrate record in ostrocoderins. Climax of invertebrate dominance. Brachiopods, trilobites and cephalopods most numerous and characteristic.
	Cambrian	First abundantly fossiliferous rocks. Low lands, mild climate and crustal stability.	Most invertebrates present. Trilobites most abundant and characteristic. Brachiopods and gastropods fairly numerous.
Proterozoic	*Lipalian Interval*	Widespread erosion. Records mostly lost.	Great development in the inyertebrates.
	Upper Proterozoic	Great vulcanism in central and eastern North America with formation of great copper, silver, gold and nickel deposits.	Sponges and foraminifera probably present. Some higher invertebrates possibly present.
	Middle Proterozoic	Sedimentary processes dominant. Formation of great iron deposits.	Bacteria and seaweeds present. Sponges and protozoa probably present.
	Lower Proterozoic	Normal sedimentary processes dominant. Earliest known glacial episode.	Bacteria and seaweeds present. Sponges and protozoa possibly present.
Archeozoic	*Unconformity*	Widespread erosion. Records mostly lost.	Development of primitive plants and animals.
	Laurentian	World-wide igneous instrusive activity.	Blue-green algae present.
	Keewatin	World-wide igneous extrusion and some sedimentation.	Primitive one-celled plants and animals possibly present.

GEOLOGIC DEVELOPMENT OF THE ANIMAL KINGDOM

(Simple forms below—complex types above)

Phylum		Class	Known Geologic Range	Common Name or Living Example
Chordata	Vertebrata	Mammalia	Triassic to present	Mammals
		Aves	Jurassic to present	Birds
		Reptilia	Pennsylvanian to present	Reptiles
		Amphibia	Devonian to present	Amphibians
		Pisces	Silurian to present	Fish
		Ostracodermi	Ordovician through Devonian	Bony-plated fish
		Cyclostomata	Devonian to present	Lamprey eels
		Acrania	No fossil record	Amphioxus
		Urochorda	No fossil record	Ascidians
		Adelochorda	No fossil record	Balanoglossus
Arthropoda	Invertebrata	Insecta	Mississippian to present	Insects
		Arachnida	Cambrian to present	Spiders
		Myriopoda	Devonian to present	Centipedes
		Onychophora	Cambrian to present	Peripatus
		Crustacea	Cambrian to present	Crayfish
Mollusca		Cephalopoda	Cambrian to present	Squid
		Scaphopoda	Ordovician to present	Tooth shells
		Gastropoda	Cambrian to present	Snails
		Pelecypoda	Ordovician to present	Clams and oysters
		Amphineura	Ordovician to present	Chitons
Molluscoidea		Brachiopoda	Cambrian to present	Lamp shells
		Bryozoa	Ordovician to present	Moss animals
Echinodermata		Holothurioidea	Cambrian to present	Sea cucumbers
		Echinodea	Ordovician to present	Sea urchins
		Ophiuroidea	Ordovician to present	Brittle stars
		Asteroidea	Ordovician to present	Starfish
		Crinoidea	Cambrian to present	Sea lilies
		Blastoidea	Ordovician through Pennsylvanian	Sea buds
		Cystoidea	Ordovician through Mississippian	Sea bladders

GEOLOGIC DEVELOPMENT OF THE ANIMAL KINGDOM—Continued

(Simple forms below—complex types above)

Phylum	Class	Known Geologic Range	Common Name or Living Example
Vermes: *Annulata*	Classes omitted	Cambrian to present	Segmented worms
Vermes: *Trochelminthes*	Classes omitted	No fossil record	Wheel worms
Vermes: *Nemathelminthes*	Classes omitted	Cambrian to present	Threadworms
Vermes: *Platyhelminthes*	Classes omitted	Pennsylvanian to present	Flatworms
Coelenterata	Ctenophora	No fossil record	Comb jellies
	Anthozoa	Cambrian to present	Corals
	Scyphozoa	Cambrian to present	Jellyfish
	Hydrozoa	Cambrian to present	Hydrozoans
Porifera	Porifera	Proterozoic to present	Sponges
Protozoa	Infusoria	No fossil record	Infusorians
	Sporozoa	No fossil record	Gregarina
	Mastigophora	Cretaceous to present	Euglena
	Sarcodina	Cambrian to present	Amoeba

(Invertebrata)

GEOLOGIC DEVELOPMENT OF THE PLANT KINGDOM

(Simple forms below—complex types above)

Phylum	Class		Known Geologic Range	Common Name or Living Example
Spermatophyta (Seed Plants)	Angiospermae (Covered seeds)	Dicotyledones	Early Cretaceous to present	Oaks, maples, elms
	Angiospermae (Covered seeds)	Monocotyledones	Early Cretaceous to present	Grasses
	Gymnosperms (Naked seeds)	Gnetales	No fossil record	Ephedra
	Gymnosperms (Naked seeds)	Coniferales	Permian to present	Pines
	Gymnosperms (Naked seeds)	Ginkgoales	Permian to present	Ginkgo
	Gymnosperms (Naked seeds)	Cycadales	Triassic to present	Cycads
	Gymnosperms (Naked seeds)	Cycadeoidea	Permian to Cretaceous	Cycadeoids
	Gymnosperms (Naked seeds)	Cordaitales	Devonian to Permian	Cordaites
	Gymnosperms (Naked seeds)	Cycadofilicales	Devonian to Jurassic	Neuropteris
Pteridophyta (Fern Plants)		Lycopodiales	Devonian to present	Club mosses
		Sphenophyllales	Devonian to Permian	Sphenophyllum
		Equisitales	Devonian to present	Horsetails
		Filicales	Devonian to present	Ferns
Bryophyta (Moss Plants)		Musci	Mississippian to present	Mosses
		Hepaticae	Silurian to present	Liverworts
Thallophyta (Thallus Plants)		Fungi	Silurian to present	Fungi
		Diatomeae	Jurassic to present	Diatoms
		Algae	Proterozoic to present	Seaweeds
		Myxomycetae	No fossil record	Slime molds
		Schizophyta		
		Blue-green algae	Archeozoic to present	Blue-green algae
		Bacteria	Proterozoic to present	Bacteria

MINERALOGY

MINERALOGY is the science that treats of the properties of minerals and teaches us to characterize, distinguish and classify them according to their properties. Prior to 1750, geology was included in the science of mineralogy, but this term has more recently become restricted to the study of the individual minerals and their relations to each other, forming an important section of the present science of geology. The science of mineralogy, however, is not confined to the study of the external characters of mineral substances, their chemical composition being equally important.

Classification. Minerals may be described and classified either in accordance with their chemical composition, their crystallographic forms, or their physical properties of hardness, fracture, color, luster and so forth, or a combination of all; and thus various systems of classification have been adopted. Most minerals crystallize in definite forms. There are not a few, however, which are not distinctly crystalline, but are earthy or occur in masses, the latter exhibiting important varieties of structure, as *laminated, fibrous, granular, reniform, botryoidal* and others. Other distinctive characteristics are *color*, which, however, varies even in the same mineral; *luster*, the character of the light reflected from the surface, and described as *adamantine, vitreous, nacreous, greasy, silky* and so forth; *fracture*, or the character of the freshly broken surface; *streak*, or the color of the powder; and *hardness*, now determined by Moh's scale. In this scale type minerals are used in an arbitrary scale, in which the hardnesses are given as from 1 to 10. Diamonds, however, are known to be from 90 to 150 times as hard as corundum, ordinarily regarded as the next hardest substance. The type minerals of Moh's scale are:

1. *Talc*, common laminated light-green variety.
2. *Gypsum*, a crystallized variety.
2.5 *Mica.*
3. *Calcite*, transparent variety.
4. *Fluor spar*, crystalline variety.
5. *Apatite*, transparent variety.
5.5 *Wernerite*, crystalline variety.
6. *Potash feldspar*, white cleavable variety.
7. *Quartz*, transparent.
8. *Topaz*, transparent.
9. *Corundum.*
10. *Diamond.*

To determine the hardness of a mineral, ascertain, by experiment, which of the minerals it will scratch and which will scratch it; thus, if a mineral will scratch fluor spar but not apatite, while the latter will scratch it, its hardness is between 4 and 5. Diaphaneity, refraction, polarization and electric properties are all distinguishing marks.

Precious and Semiprecious Stones. Minerals which, because of their beauty, hardness and rarity, are prized for use in ornamentation, especially in jewelry, are classified as "precious stones." The diamond, ruby, sapphire and emerald are the only stones which are, strictly speaking, entitled to be called "precious" in this sense. But the opal, on account of its beauty, is often included with the precious stones, as is also the pearl, which is not really a stone, but a secretion of a shellfish. The following dictionary presents distinguishing points on the better known stones:

Agate. A semitransparent, uncrystallized variety of quartz, presenting various tints in the same specimen. Its colors are delicately arranged in stripes or bands, or blended in clouds.

Alexandrite. A variety of chrysoberyl found in the mica slate of the Ural Mountains. It is of a rich garnet color by artificial light, by daylight of a dark moss green. It is the only stone that so changes. The finest specimens of alexandrite are nearly as valuable as diamonds.

Almandine. A common maroon-red variety of garnet.

Amethyst. A variety of crystallized quartz, of a purple or bluish-violet color, of different shades. It is much used as a jeweler's stone. The lighter colored amethysts come from Brazil, the deep purple ones from Siberia. In value the amethyst is about equal to garnet.

Aquamarine. A transparent, light-blue variety of beryl, used as a gem.

Aventurine. A variety of translucent, reddish quartz, spangled throughout with scales of yellow mica or hematite.

Beryl. A very hard mineral, of much beauty when transparent. It occurs in hexagonal prisms, commonly of a green or bluish-green color, but also blue, light-blue, yellow, pink and white. It is a silicate of aluminum and beryllium. Beryls are usually very delicate in color. Their value is about four dollars per carat, except for emeralds (which see).

Bloodstone. A dark green, uncrystallized quartz sprinkled with red jasper, from which it takes its name. Also called Heliotrope.

Cameo. A figure cut in relief in stone or shell which often is composed of different colored layers. The value depends upon the artistic merit of the engraved figure.

Carbuncle. A term used by the ancients to designate any deep red, transparent stone, but expecially applied to garnets. Today the carbuncle is a deep red garnet cut *en cabochon* (not faceted).

Carnelian. A variety of chalcedony, of a brownish-red color. It is moderately hard and capable of taking a good polish. It is sometimes used for seals. Its entire use is not extensive today.

Cat's-eye. A variety of quartz or chalcedony exhibiting shifting reflections from within, like the eye of a cat. The name is given to other gems affording similar effects, especially to the chrysoberyl. A fine specimen of the latter about three-eighths of an inch across might be worth one hundred dollars or more.

Chalcedony. An indistinctly crystalline, translucent variety of quartz, of a whitish or grayish color and with a luster nearly like wax.

Chrysolite. A transparent gem, composed of silica, magnesia and iron, of a yellow to green color. It is also known as *peridot*. It is little used.

Chrysoprase. An apple-green variety of chalcedony. Its color is due to nickel.

Dendrite. A stone in which are branching figures, resembling shrubs of trees, produced by a foreign mineral, usually by an oxide of manganese, as in moss agate.

Diamond. A precious stone or gem excelling in brilliancy and beautiful play of prismatic colors, and remarkable for extreme hardness. It occurs in many hues—green, rose, straw, yellow and others—but the straw-colored diamonds are the most common. The diamond is a native carbon occurring in isometric crystals, often octahedrons, with rounded edges. It is the hardest substance known. Diamonds are said to be of the *first* water when very transparent, and of the *second* and *third* water as the transparency decreases.

Diopside. A crystallized variety of pyroxene (a silicate of lime and magnesia), of a clear light-green color; also called *mussite*.

Emerald. A precious stone of a rich green color; it is the most valuable variety of beryl (which see).

Epidote. A mineral, commonly of a yellowish-green to greenish-brown color, occurring granular, massive, columnar and in crystals. It is a silicate of alumina, lime and oxide of iron, or manganese.

Essonite. Cinnamon stone. A variety of garnet, yellow to brown in color. It is not much used.

Fire Opal. See Opal.

Fluorite. Calcium fluoride, a mineral of many different colors—white, yellow, purple, red, green and others—often very beautiful. When crystallized it is commonly in cubes with perfect octahedral cleavage. Some varieties are used for ornamental vessels. Also called *fluor spar* or *fluor*. The colored varieties are known as *false ruby, false emerald, false topaz, false sapphire* and *false amethyst*. It is too soft for use in jewelry.

Flint. A massive, somewhat impure variety of quartz, in color usually gray to brown or nearly black, breaking with a conchoidal fracture and a sharp edge. See Quartz.

Fluor spar. See Fluorite.

Garnet. A mineral having many varieties, differing in color and in their constituents, but with the same general chemical formula. The commonest color is red; the luster is vitreous, or glassy; the hardness is greater than that of quartz. The common crystal forms are the dodecahedron and trapezohedron. Besides the red varieties there are also white, green, yellow, brown and black garnets.

The garnet is a silicate with various bases, such as alumina-lime (grossularite, essonite), alumina-magnesia (pyrope), alumina-manganese (spessartite) and chromium-lime (ouvarovite—color emerald green). The transparent red varieties are used as gems. The garnet was the carbuncle of the ancients. Garnet is a very common mineral in gneiss and mica schist.

The finest specimens of red garnets come from Arizona, and a single stone is worth about two dollars. A green variety that comes from Russia is worth about half as much as the diamond.

Golden Beryl. See Beryl.

Heliotrope. See Bloodstone.

Hematite. An important ore of iron, the sesquioxide, so called because of its red color when in the form of powder. It occurs in splendid rhombohedral crystals and in massive and earthy forms, the last being called *red ocher*. It is now seldom used in jewelry.

Hyacinth. A reddish-brown variety of zircon, sometimes used as a gem. It resembles closely a dark Spanish topaz, and is worth a trifle more than a garnet.

Idocrase or **Vesuvianite.** A mineral occurring in tetragonal crystals, also massive; brown to green in color, rarely sulphur yellow or blue. It is a silicate of alumina and lime, with some iron and magnesia. It is found at Mt. Vesuvius. It is little used.

Indicolite. A variety of tourmaline of an indigo-blue color.

Intaglio. A figure cut in a stone or shell so as to be depressed below the general surface, which may be the same as or a different color from the material exposed by the cutting. The value depends upon the artistic merit of the work.

Iolite. A silicate of alumina, iron and magnesia showing bright blue and yellow colors when viewed from different directions, and with a vitreous or glassy luster. It is remarkable for its dichroism. Also called *dichroite*.

Jacinth. Same as hyacinth.

Jade. A stone commonly of a pale to a dark green color, but sometimes whitish or showing light tints of other colors. It is moderately hard and very tough, capable of a high polish. It is used for ornamental purposes and for implements, especially in the Orient and among many primitive peoples.

Jasper. An opaque, impure variety of quartz, of red, yellow and other dull colors, breaking with a smooth surface. See Quartz.

Kyanite or **Cyanite.** A mineral occurring in thin-bladed crystals and crystalline aggregates, of a sky-blue color. It is a silicate of aluminum. It is remarkable for differing greatly in hardness when scratched in different directions. It is slightly used in jewelry.

Labradorite. A kind of feldspar, commonly showing a beautiful play of green, blue, yellow and copper colors, and, hence, used for ornamental purposes. The best specimens come from Labrador.

Lapis Lazuli. A mineral of fine dark blue color, usually occurring in small rounded masses. It is usually a silicate of alumina, lime and soda, with some sodium sulphide. It is often marked by golden yellow metallic spots or veins of sulphide of iron. It is much valued for ornamental work.

Moonstone. A nearly pellucid variety of feldspar, showing bluish pearly or opaline reflections from within. The best specimens come from Ceylon. Moonstone is worth a few dollars a carat.

Nephrite. A hard, compact mineral, of dark green color, formerly worn as a remedy for diseases of the kidneys, whence its name, *kidney stone*.

Obsidian. A kind of glass produced by volcanoes. It is usually black in color and opaque, except in thin splinters.

Olivine. A common name of the yellowish-green mineral chrysolite, especially of the variety occurring in eruptive rocks. See Chrysolite.

Onyx. Chalcedony in parallel layers of different shades of color. It is used for making cameos, the figure being cut in one layer with the next layer as a background (see Cameo). It is stained black and used to make mourning jewelry.

Opal. A mineral consisting, like quartz, of silica, but inferior to quartz in hardness and specific gravity. The precious opal shows a peculiar play of colors of delicate brilliant tints, and it is highly esteemed as a gem. One kind, with a varied play of colors in a reddish ground, is called *harlequin opal*. The *fire opal* (of Mexico) has colors like the red and yellow of flame. This is not the cheap so-called "Mexican opal." A spherical opal about three-eighths of an inch in diameter, or an oval flat opal about half an inch long, if of finest quality, might be worth about sixty dollars. A Mexican opal of the same size might be worth only fifty cents unless old, uncracked and very attractive.

Pearl. A shelly concretion, usually rounded, having a brilliant luster, with varying tints, formed in the mantle, or between the mantle and shell, of certain bivalve mollusks (especially in pearl oysters and river mussels) and sometimes in certain univalves. Its substance is the same as nacre or mother-of-pearl. Pearls which are round or nearly round and of fine luster are highly prized as jewels. They are sold by grain (quarter carats) instead of by carats.

Pyrope. A red variety of garnet, used as a gem.

Rhodonite. Manganese spar, or silicate of manganese, a mineral occurring crystallized and in rose-red masses. It is used almost entirely for ornamental purposes as in slabs and blocks. It is often veined with black.

Rock Crystal or **Mountain Crystal.** Any transparent crystal of quartz, particularly of limpid or colorless quartz. A sphere of rock crystal of absolutely perfect clearness, about five inches in diameter, is worth at least $20,000.

Rose Quartz. A pinkish or red, usually badly flawed, variety of quartz.

Rubellite. A variety of tourmaline varying in color from a pale rose to a deep ruby, and containing lithium. It is a little more valuable than garnet.

Ruby. A precious stone of a carmine-red color, sometimes verging to violet, or intermediate between carmine and hyacinth red. It is a crystallized variety of corundum. The ruby from Siam is of a dark color and is called *oxblood ruby*. It has about the same value as the diamond. The ruby from Burma, called the *pigeon-blood ruby*, is of a lighter color and several times more valuable than the oxblood. A fine pigeon-blood ruby, weighing two carats, may be worth more than $6,000.

Rutile. A mineral, usually of a reddish-brown color and of billiant, adamantine luster, occurring in tetragonal crystals.

Sapphire. Gem corundum or aluminum sesquioxide. Gem miners and dealers use the term for material of any color, as pink, white and other sapphires. The name sapphire, alone, is applied by jewelers only to the blue stone. The best specimens of the blue variety are nearly as valuable as the diamond.

Sard. Same as Carnelian.

Sardonyx. A variety of onyx consisting of sard and white chalcedony in alternate layers. See Onyx.

Spinel. A mineral occurring in octahedrons of great hardness and various colors, as red, green, blue, brown and black. The red variety is the gem *spinel ruby*. It consists essentially of alumina and magnesia, but commonly contains iron and sometimes also chromium. Fine specimens of spinel ruby are worth rather more than one-fourth as much as diamond.

Sunstone. Aventurine feldspar; aventurine.

Topaz. A mineral occurring in rhombic prisms, generally yellow and pellucid, also colorless, and of greenish, bluish or brownish shades. It sometimes occurs massive and opaque. It is aluminum fluo-silicate, and is occasionally used as a gem. It is but little more valuable than garnet, except in the case of unusually fine specimens. Yellow varieties when heated sometimes turn pink.

Tourmaline. A mineral occurring in three-sided prisms. Black tourmaline is the most common, but there are other varieties, as the blue (*indicolite*), red (*rubellite*), green, brown and white. The red and green varieties, when transparent, are valued as jewels. The finest ones come from California and Brazil, and are worth from four to five times as much as garnets.

Turquoise. A hydrous phosphate of aluminum containing a little copper. It is blue or bluish-green in color, is nearly opaque, and usually occurs in kidney-shaped masses with a nodular surface like that of a bunch of grapes.

Unio-pearl. A pearl secreted by a fresh-water mollusk, in distinction to those secreted by the ordinary marine pearl oyster.

Verd Antique. A mottled-green, serpentine marble. Also a green porphyry which is called *oriental verd antique*.

Zircon. A mineral occurring in tetragonal crystals, usually of a brown or gray color. It consists of silicon and zirconium. It is harder than garnet. The transparent varieties are used as gems. The reddish brown variety is called *hyacinth*. The *jargon* is a colorless, pale yellow or smoky-brown variety from Ceylon.

THE WEATHER

WHAT is the weather going to be? Is it going to rain or snow? Is the sun going to shine? Will there be a frost? These and a thousand other questions of like import are asked daily by people all over the world, whether they be young or old, rich or poor, living in the most palatial city house or in the simplest rural cottage. All are interested in what the weather will be. No other subject is such a general topic of conversation, simply because no other subject commands so much interest. Yet in spite of all this interest, relatively few people know even the scientific fundamentals in a study of the weather, and probably more untruths are told about the weather than about any other single subject.

Meteorology a Science. There are certain simple fundamental facts of science, readily available in textbooks, that can be used as a measuring stick in deciding what and what not to believe about the weather. These facts have been collected and arranged in orderly fashion, and the study of them is the field of *meteorology*. These are the facts that the observer uses in forecasting the weather for the next twelve, twenty-four or thirty-six hours. Unfortunately, the laws which govern weather are not sufficiently well known to forecast for periods of much greater length.

Clouds. Many of our weather changes are foretold in *clouds*. Many kinds of weather have their own kinds of cloud forms, which are indicative of impending weather. Thus there has grown up a cloud lore that incorporates many scientific facts. Although clouds are merely a collection of minute but visible water particles condensed from the water vapor of the air by cooling, the form occupied is determined very definitely by the existing atmospheric conditions. There is no real distinction between the formation of a fog and a cloud; in fact, "a fog is a cloud on the earth; a cloud is a fog in the sky." Yet the interpretative values of a "cloud on the earth" and a "fog in the sky" are very different. Both, however, are caused by

sufficient cooling to condense the water vapor in the air into minute droplets.

Cloud Forms. Clouds are classified according to their appearance. There are four general types: *cirrus*, *stratus*, *cumulus* and *nimbus*. Aside from these standard types there are innumerable variations and combinations. Many words are compounded to express these forms, as fracto-cumulus, fracto-stratus, alto-cirrus, alto-stratus, cirro-cumulus and cumulo-nimbus. Besides these, there are others such as scarf, riffle and billow. Although these major groups received their names over one hundred years ago, many cloud problems still remain unsolved.

Cirrus Clouds. The cirrus are detached clouds of delicate appearance, threadlike or hairlike in structure, and feathery or plumelike in form. They may resemble isolated tufts or curls of hair, or may be in long straight or curved filaments ending in tufts, not uncommonly arranged in bands converging more or less at a point on the horizon. "Cat's whiskers" and "mares' tails" are cirrus clouds. They are usually in the upper regions and are our highest clouds, five to ten miles high and in regions of extreme cold. Naturally, at this height they must be made up of snow or ice particles.

The altitude, however, is not vital provided conditions for their formation are favorable. The extreme cold in which they are found necessitates a limited amount of moisture; consequently they are never heavy and do not obscure the form of sun or moon. When these bands thicken and become solid sheets they are the forerunners of storm and the sailor prepares for high seas. If, however, they become thinner and die out, clear weather for several days may be expected.

Stratus Clouds. The stratus are our lowest lying clouds, generally less than one-half mile above the earth's surface. "A uniform layer of cloudlike fog not lying on the ground" is the international definition given to this form. The lack of observable structure differentiates it from all other forms. It is the cloud that produces our drab, chilly, cheerless days for it shuts off the sun completely. The so-called "high fogs" of California where a deep sea fog drifts over a relatively warm land, evaporating the lower part, is one of this type. At times such a cloud sheet becomes broken by winds and then the term "fracto-stratus" is applied to it. There are many other variants.

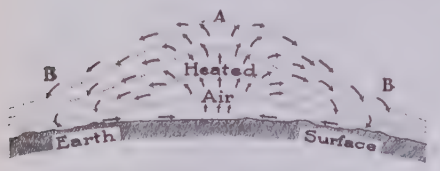
Cumulus Clouds. A third general type is the cumulus cloud. This is a "thick cloud of which the upper surface is dome-shaped and exhibits protuberances, while the base is generally horizontal." They are the great billowy heaps, or "wool packs," that one is likely to see in mid-latitudes (the intermediate area between the tropics and the polar regions) on a summer afternoon. They are formed by the warmed air in the lower regions being pushed up into colder regions. They increase with the heat of the afternoon, usually growing smaller as evening approaches. Because they indicate rising air currents, they are more commonly seen over bodies of water at night. Forest fires often produce cumulus clouds which, when high and well broken up, give the sky a flaky appearance and are known as "cirro-cumulus" or "mackerel sky."

Nimbus Clouds. The fourth general type, the nimbus, is the dense, dark, shapeless rain cloud. The average altitude of its under surface is little more than one-half mile. These clouds are usually too heavy for the sun to penetrate, consequently their under parts are dark, gray or even black. When they are broken up by strong winds they are known as "fracto-nimbus."

Relationships Between Clouds and Weather. Clouds bear a definite relationship to a wide range of weather phenomena. Their movement and velocity is generally the same as that of the stratum of air in which they float. They are generally lower in winter than in summer; and lower in high than in low latitudes, due to the differences in temperature and relative humidity. In mid-latitudes, the cumulus is more common in summer and the stratus in winter. Also the sky is markedly different in the trade wind belt from that of the belt of the westerlies, in desert from that of humid regions, in morning from afternoon or night. Each cloud form has its significance and each change its corresponding weather change. Because clouds are so sensitive to changing atmospheric conditions, they are, to those who can read their story, excellent forecasters.

The Air. Different kinds of weather result, of course, when different kinds of atmospheric conditions prevail. The atmosphere, or air, is a real substance, although we are hardly aware of its existence. We know that it is a substance, for it has been liquified. We know not only that air can be compressed into a liquid, but also that it is elastic. An automobile tire filled with a liquid would be less resilient than if made of solid rubber, because a liquid, for all practical purposes, is neither compressible nor elastic. We know also that the air has weight, for if we balance an electric light bulb on a scale and then melt a spot on the bulb with a blowpipe and permit the air to rush in without losing any glass, we find that the bulb with the hole will be heavier than it was with the air pumped out. From experiments we learn that a cubic foot of air at sea level weighs approximately one and one-fifth ounces.

Compressibility of Air. From the fact that the air has weight and is compressible, many interesting phenomena may be explained. Thus a cubic foot of air is heavier in the lower than in the upper air. If it were not for this principle, the upper layers of air would be as dense as the lower, and balloons would rise and float on the outer surface of the air as a ship does on water. Moreover, it is largely due to the rarity of the upper air that airplanes are limited in their altitude records, and that high mountain peaks, as Mount Everest, have never been climbed.



Air Pressure. Since air has weight, the lower layers of air are weighted down by all the air mass above it; and this total weight, or "pressure," as it is called, is equal at sea level to approximately fourteen and seven-tenths pounds per square inch. The column of air resting upon a square foot of surface at sea level will therefore weigh over one ton. The weight of this air column, spoken of as "air pressure," is equal to a column of mercury thirty inches high. The total weight of the air is equal approximately to a layer of water covering the whole earth to a depth of thirty-three feet. Although the atmosphere extends out into space indefinitely, the higher the altitude the rarer the air becomes because it is less compressed by the lesser weight of the air above it. Thus it is estimated that, although the atmosphere extends out into space hundreds of miles, half of the atmosphere, by weight, lies below an altitude of three and six-tenths miles above sea level, and that approximately three-fourths of it lies below our highest mountain peaks.

This air pressure is measured by a *barometer*. The instrument most commonly in use is made of a glass tube, sealed at one end, and filled with mercury. It is then inverted into a dish and the mercury flows out, leaving a vacuum above, until the air pressure on the mercury in the dish is equal to the height of the mercury column. If there is an increase in air pressure, the mercury column will rise in the tube and we speak of it as a "high barometer." If, on the other hand, the air pressure decreases, the mercury column falls and we speak of it as a "low barometer." This, in a measure, is the meaning of the words "high" and "low" on a weather map; pressures less than thirty inches are considered as making up a low, and above thirty inches as a part of a high. As the atmospheric pressure decreases with altitude the height of mountains may be measured with a barometer. Barometers made especially for this purpose are known as "aneroid" barometers or simply as *aneroids*, or *altimeters*.

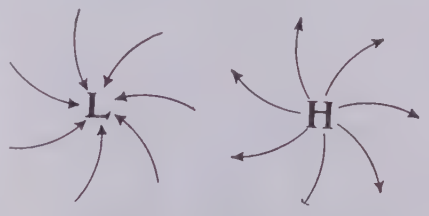
Air Density. The density of the air, and consequently the pressure that is exerted, may be changed with a variation in temperature. As is the case with most materials with which we are acquainted, an increase of temperature causes an increase in space occupied (if the space is not restricted) and consequently becomes less dense; in other words, it becomes lighter per unit amount. If, under normal conditions, a cubic foot of air weighs one and one-fifth ounces, then a cubic foot of colder air will weigh more, and a cubic foot of warmer air less, than one and one-fifth ounces. This principle accounts for practically all air movements or winds. Near the earth's surface cooler and heavier air flows to a warmer area and pushes the warmer and lighter air up. Thus, it is as safe to say that winds are currents of air always flowing down slope, as it is to say that water always flows down hill. Water in a stream may be forced over a boulder, but its general trend is downward. So with air; it may be forced over a house or even over a mountain, but its general trend is downward. As swift waters are caused by steep topographic slopes, so strong winds are caused by steep barometric slopes.

Cause of Winds. If winds always flow down barometric slopes one may well ask why all the air does not get to the bottom. Similarly one might ask, why, since all streams flow to the sea, do they not after a time stop running. The answer, of course, is simple: the water evaporates, due to the sun's heat, and is carried back by the winds to the lands, there to start its ceaseless flow to the sea again. The same holds true with air movements. Some parts of the earth get warmer than others, thus expanding the lower layers of air and lifting the whole mass above. This will cause a movement in the

upper regions away from this domed area into areas where the air has not expanded in this manner. This flow in the upper regions toward areas not thus expanded will make the column of air in the colder area heavier. The air from this area will move at the earth's surface to the warmer region, to make the same ceaseless round. Thus, in general, winds flow from colder to warmer areas at the earth's surface, from places of descending currents to places of ascending ones, from areas of high pressures to areas of low pressures. Unequal heating of air, therefore,

Unequal Heating and Air Currents
The diagram illustrates air movements when certain areas (A) are heated more than other areas (B). The areas show the probable currents of air and the dotted lines suggest in general the barometric slopes.

causes currents to rise in one region and to come down in another. The accompanying diagram makes this principle clearer.



Winds and Weather. Winds are very important factors for weather conditions in a host of ways, chiefly perhaps, in the distribution of moisture. Of course if there were no winds there could be no clouds, no rains and no snows. We could hardly have what we call weather. Winds may take moisture from a region or bring moisture to it. Thus there are deserts where, in a sense, it never rains or snows, and there is tremendous evaporation if any water is available. Such areas are found not only on the land but also over the ocean where, because of this tremendous evaporation, the ocean waters are much saltier than in the rainy regions. Then there are regions where the precipitation vastly exceeds the evaporation.

Precipitation. Evaporation is a process familiar to all. Its rapidity may be increased by raising the temperature and also by increasing the movement of the air so as to replace the moisture laden air with dryer air. Heat, however, is the vital principle. In order to dry the air we heat it—not to drive out the moisture but to increase the holding capacity. Then, by reversing the process (and this is the only way) we can get the moisture out by cooling the air sufficiently. Thus, to get the moisture out of the air—be it in the form of dew, frost, clouds, rain, snow, hail or in any other form—that air must be cooled; the cooler the air, the less moisture it can hold. Perhaps we have had the experience, on a winter's day, of opening the door of a laundry and forthwith finding the air suddenly turned to steam; or of having our eyeglasses coated over on entering a warm room, or of seeing a cold water pitcher "sweat" on a warm summer afternoon. The explanation for all these occurrences is that the air has been cooled to a point where it can not hold the moisture which it easily held at higher temperatures. This cooling must happen if there is to be precipitation in any form.

A decrease in temperature always precedes any form of precipitation of moisture from the air. Thus the reason why dew does not fall but rather condenses on the solid object is because that object is cooler than the air. For the same reason moisture condenses on a pitcher containing ice water. If the temperature at the point of condensation, the so-called "dew point," be below freezing, then instead of dew there will be frost. When, in the upper regions of the moisture laden air, the temperature is lowered sufficiently to reach the dew point, clouds will result. If the temperature is above freezing and the condensation heavy enough, rain will result; if below freezing, snow will form. Sometimes the upper air is so cold that snow is formed, but the lower air is warm enough to melt the snow, and it therefore comes down as rain. In an ice storm the objects on which the rain falls, such as trees, telephone wires and the like, are colder than the air above.

Thus some regions have much more rain than others. The simple explanation is that in regions of heavier rainfall there is a greater tendency for the air to rise and cool. This cooling is brought about principally by the rising air. The greater rainfall, therefore, is on the windward slope of mountains, and the lesser on the leeward side. Areas with rising air will have rain; areas with falling air currents will have little or no rain; air blowing from a colder to a warmer region will be a drying wind and the sky will be cloudless; air blowing from a warmer to a colder region will be a moisture-bearing wind and the skies will be overcast.

There are a number of areas which have more or less permanent low (ascending air) or permanent high pressures (descending air). In some cases they are seasonal. Thus over Asia in summer, because the land gets warmer than the bordering waters, a low pressure develops, pulling in the air from all sides to take the place of the rising air. In winter the reverse process takes place because the land becomes colder than the water and a high pressure is developed. During the high pressure period there are descending currents of air becoming somewhat warmer as they approach the earth, and therefore this is the dry

High and Low Pressure Areas
This diagram shows in a general way the chief surface directions in related high and low pressure areas, provided there were no modifying factors at the earth's surface. It will be noted that the wind in the high, as it comes down from higher regions, blows in broad currents toward the center of the low where it must rise to repeat the same round.

season of the year. On the other hand, in the south Pacific, west of central Chile, there is a permanent high continuing throughout the entire year. As a result, in that part of South America is one of the great desert regions of the world.

Fundamentals. The principles discussed —(1) the effect of heat on the density of the air and (2) the effect of heat on the relative humidity of the air—are the great foundation stones in a study of the weather. Whatever will bring about changes in these two conditions will also bring about changes in the weather. One of the dominant reasons for mid-latitude weather like that in the United States and Europe is the constant migration and succession of lows and highs from west to east. Each of these has its own specific characteristics, but, in general, in these low pressure areas the wind blows in great curves inward, counterclockwise and upward. In the high pressure areas the winds come down, go clockwise and outward. Within the influence of the lows the air rises and consequently cools, thus reducing the moisture-holding capacity; as a result, clouds are formed and rains may fall. Within the influence of the highs the colder air from the upper regions moves toward the earth. Although the air is cold as it starts on its downward path, it is getting warmer and warmer the nearer it comes to the earth, and consequently is a drying wind bringing clear and cool weather. It is quite evident that, could we know all about these lows and highs, we could tell all about the weather.

The weather map published by the United States Weather Bureau is a record of the weather conditions that dominate the whole country. All weather predictions are made from the data gathered by the weather bureau and much of the data may be read from the map. The weather map, therefore, is a storehouse of information, and every intelligent person should be able to read it.

All forecasts given on the weather map are based on the general assumption that the lows and highs carry with them the same weather conditions that prevail at the time of the forecast with certain modifications which, in the past, have been generally true. Thus the direction of winds may be foretold if the position of the low or high can be foretold, and the strength of the wind by the barometric gradient. A strong low over northern Texas will probably be over the Great Lakes region in twenty-four hours, and over New England in another twenty-four. If rain accompanied in Texas, quite surely it will rain in the Great Lakes region the next day, and in New England the next. Changing temperatures are shown on the weather map by dotted isothermal lines and migrate in a general way with the highs and lows.

However, the weather observer does not always succeed, for the simple reason that the weather does not turn out as it might well be expected to do, judging from what happened under similar conditions in the past. These centers may not follow the exact course that others before them generally have done; or for some unknown reason they may increase or decrease the speed of travel; they may grow stronger or weaker; they may disappear, or new ones may form. Besides this there are a host of other possibilities away from the ordinary conditions. Thus there has arisen the saying: "There is nothing certain about the weather except that it changes." Yet, in spite of this uncertainty, the science of meteorology has definitely established a host of scientific laws and principles.

PHYSICS

WE LIVE in a world of matter and energy. Everywhere we see nature constantly changing, heavenly bodies in motion, and we are told that the earth is traveling more than a million and a half miles a day. We are familiar with two kinds of objects: one we classify as living, such as grass, eagles, fish and man; the other we denote as non-living, and includes such objects as stone, glass, air and the moon. For convenience in grouping scientific knowledge, it is customary to make two great divisions of science: biological science, which deals with living matter, and physical science, which deals with inanimate matter.

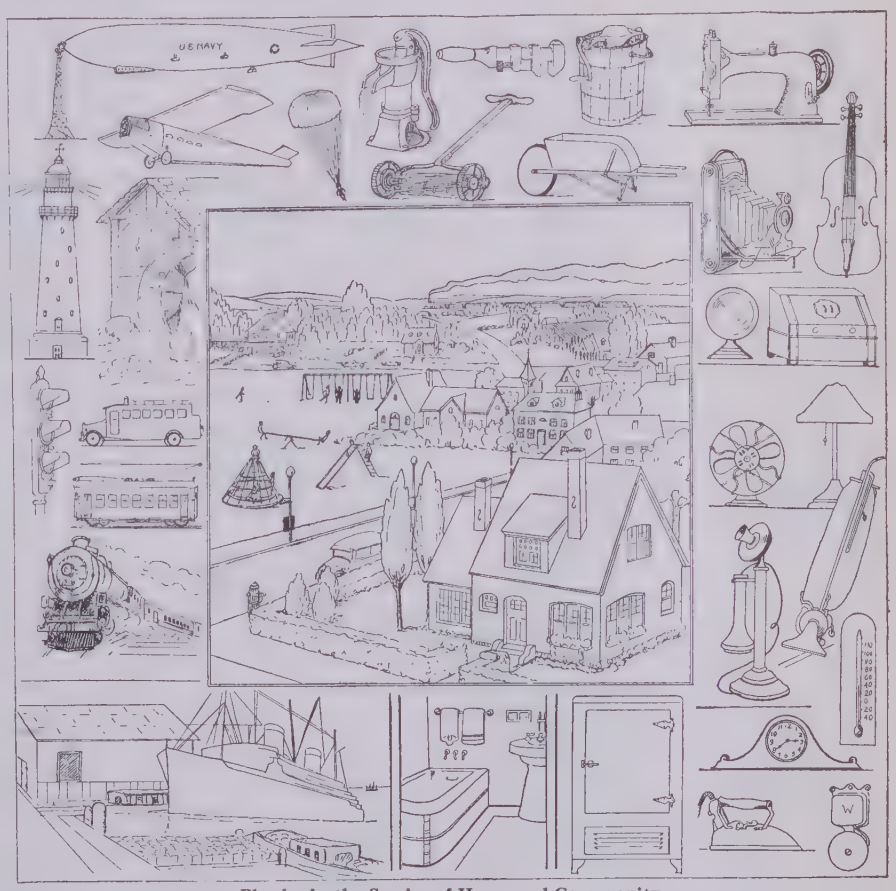
Under this classification, chemistry is a branch of physical science and geology largely belongs in this grouping. It is impossible to carry on a study of biological science without the use of many facts obtained from the physical realm. In nature there are no limiting fields of science. In studying about the growth of a plant we are lead into all general branches of systematized knowledge. Not only in the natural world but in an artificial world as well do we find that we are surrounded by countless devices made by man. To be of service, these objects, made of matter, require energy. The inventor who devises new machines must have at his command many important facts and principles from the domain of physics. The engineer is merely a physicist trained in a special practical field. Indeed, a broader knowledge of physics will give one an enrichment of life, a deeper appreciation of the many creations of skillful workers, and a better understanding of the natural wonders of the world.

THE MAJOR DIVISION OF PHYSICS

To systematize the study of physics it is customary to group the subject matter around the major topics of heat, mechanics, light, sound, electricity and magnetism.

Heat deals with energy changes, temperatures, changes in size through expansion, and with changes in state and transmission of heat. Some knowledge of heat is essential in the use of most mechanical contrivances and is required for the planning of the various heat engines, heating devices, refrigerators and refrigerating plants.

Mechanics includes the effect of force on matter, questions of motion, power, machines, pressure, flow and buoyancy of fluids. The effect of force on liquids is known as hydraulics, and that upon gases, as pneumatics. Mechanics is at the foundation of such engineering as bridge and tunnel building, boat making, transportation on earth and in the air, power plant and dam construction and hydroelectric development.



Light and sound have to do with two of our most prized senses, for we learn more through sight and sound than through all other means together. Without light we could not read nor could we see objects. Without sound we would hear nothing. Sound covers the principles of mechanical vibration by which music is produced. Light explains the relations of ether vibrations by which harmonious colors result.

Electricity and magnetism make possible electric transportation, much of our communication with people at a distance, electric heating and lighting, magnetic cranes, X-rays, violet rays and infra red rays used by physicians in treatment of disease.

Altogether, physics provides the foundation for utilizing the forces of nature for man's comfort and enjoyment, and for the enrichment of his life. And now that we have briefly outlined the field that physics covers in the practical affairs of the world, let us consider the science from a more technical standpoint.

Physics is the science which deals with the phenomena of the material world. The material world consists of matter, energy and ether. Matter is anything that has weight, as iron, water and air. There are numberless kinds of matter. Energy is the capacity to do work. There are five kinds of energy, namely: heat, light, mechanical energy, chemical energy and electricity. Ether is a weightless medium which many scientists believe fills all space, and which makes possible the passage of energy by radiation. Thus heat and light are brought from the sun to the earth as ether waves, and ether waves carry electrical energy from the broadcasting stations to radio receiving sets. Matter and energy are employed in harmonious relationships for all manifestations in the physical world about us. Neither is of any value except by association with the other.

Molecules. All matter is composed of tiny particles called molecules. We would need microscopes far more powerful than any that exist to see one of these molecules. The smallest molecule is that of hydrogen. To make the molecules that are required to fill a single glass with water requires about eight million millions of millions of millions of molecules of hydrogen and half as many molecules of oxygen. In a solid, as a piece of iron, the molecules are separated by spaces greater than the diameter of the molecules. In gases, the molecules are much farther apart than in solids and liquids. One cubic inch of water makes about 1,700 cubic inches of gas (steam), but there are the same number of molecules in the cubic inch of water as in the 1,700 cubic inches of steam. In gases and liquids, each molecule has freedom of motion and may circulate so that it has a new set of neighboring molecules from time to time. In a solid, a molecule keeps in one place. The same molecules as neighbors always surround it.

Physics in the Service of Home and Community
Physics plays an important part in the activities and equipment of the home and community.

HEAT

Heat is a form of energy resulting from the vibrating motion of molecules in matter. All molecules vibrate. Increase in the vibrating

energy produces a rise in temperature. Vibrating molecules act upon the ether which surrounds them and set up ether waves. It may be in this way that the intensely hot sun sets up ether waves, some of which are radiated to the earth. When ether waves are received by matter, some of them are absorbed, thus causing an increase in molecular vibration and consequently a rise in temperature. In conduction, heat is carried along from molecule to molecule. Metals are good conductors of heat. Asbestos, glass and air are poor conductors of heat. Our wool and fur clothing keep the heat of the body in largely because of air enclosed and held by the fibers of the material.

Absorption and Radiation. Dull, rough, black surfaces absorb heat better than bright, smooth, white surfaces. Surfaces which absorb heat best also radiate heat best. If it is desired to have a device give out radiant heat quickly, its surface should be dull and rough. This is the practice in making radiators. If it is desired to hold the heat in, have a polished, bright surface as is found on the teakettle and teapot. Hot coals in a furnace or a stove radiate intense heat to the walls about. Radiated heat from the walls of the oven supplies most of the heat for baking.

Effects of Heat. The importance of heat lies in the different effects produced by it. The most significant of these are as follows: Heat may cause (1) change in size, (2) change in temperature, (3) change in state, (4) change in composition.

Expansion. Most bodies increase in size, or *expand*, when heated, and *contract* when cooled. A long iron bridge has one end fastened and the other end on rollers, with a space for it to move outward in summer and back in winter. A cold thick glass will sometimes crack when boiling water is poured into it because glass conducts heat slowly, and the inside, which is heated first by the water, expands more than the outside and so puts the glass under such strain that it breaks. A thin glass is much less liable to crack. Quartz glass expands so little that when heated red hot it can be plunged into cold water without cracking, whereas ordinary glass, under the same conditions, will be shattered into hundreds of fragments. The swelling of wood in the house in summer is due more to the absorption of moisture than to expansion by heat, because when the artificial heat used in the winter comes on, the wood dries out and shrinks.

Temperature. The conditions of matter which we designate as hot, warm and cold are due to the intensity of vibration of the molecules. When we add heat to a body and its molecules take on additional vibrating energy, the body acquires a higher temperature. The loss of this vibrating energy results in a lowering of temperature. Temperature is often confused with the amount of heat. Temperature is measured in degrees—Fahrenheit degrees in the English system and Centigrade degrees in the metric system. Heat is measured in British Thermal Units (B.T.U.). One B.T.U. is the amount of heat required to warm one pound of water 1°F. In metric units, heat is measured in calories. One calorie (small calorie) equals the amount of heat required to warm one gram of water 1°C. A large calorie equals 1,000 small calories; the large calorie is used in measuring the heating value of foods. Changes in temperature are usually measured by means of a thermometer. Very high temperatures are measured by means of pyrometers. We use mercury or colored alcohol in our common thermometers. The expansion of a liquid when heated makes it possible, when a suitable scale is provided, to use this change in size in measuring temperature.

Mercury can be used for measuring temperature as high as its boiling point, 670°F. And in a nitrogen filled thermometer, with a strong, glass tube to stand the pressure, it is possible to measure temperature above 700°F. Mercury can register —39°F. before it freezes. Alcohol can register temperature down to —200°F. before it freezes. It is therefore useful in cold latitudes.

Water in Three States
The solid (ice), liquid (water) and gaseous (steam) states of water are all shown here.

When healthy, the human body has a temperature of 98.6°F. Temperatures below this are subnormal, and those above indicate fever; 100° is slight fever, 102° moderate fever, 104° high fever. Above 104° is very high fever and indicates an extremely dangerous condition. It is always best to call a physician if the body temperature gets to 101° or over.

We keep our living rooms at about 70°F. If the relative humidity (percent of saturation) is 60 to 70, we may be comfortable at 68°F.; but when the air gets very dry, that is, when the relative humidity is low, the rapid evaporation of moisture from the body cools us, so that we must have the room at a higher temperature. The heat in our body is produced by the oxidation of the foods we eat. This oxidation goes on in all the cells of the body.

States of Matter. The state of matter—solid, liquid or gas—is, in most cases, determined by its temperature. Under normal conditions water below 32°F. is *solid* (ice); between 32° and 212°F. it is *liquid* (water); and above 212°F. it is *gas* (steam). Water changes into a gas at all temperatures. When this change takes place at the surface, it is called *evaporation*. When water at sea level is heated to 212°F., bubbles of gas (steam) form in the bottom of the container where heat is applied. These bubbles rise through the liquid and escape. This process is called boiling. *Vaporization* is a term that includes both evaporation and boiling. Steam is at the same temperature as the boiling water from which it comes, but it has stored in it a large amount of heat absorbed during the change in state. It is this stored, or latent, heat which is liberated when steam condenses in the radiators which warm our rooms in steam-heated buildings.

When one pound of steam condenses it gives up 965 B.T.U. and the resulting water is at the same temperature that the steam was. It is because of this heat that a burn from steam is much severer than a burn from boiling water which has just as high a temperature.

Solids like wax, lead, ice and lard can be changed to liquids by means of heat. The process is called *melting*, or *fusion*. Each substance has a definite temperature at which the change occurs. This temperature is the melting point of the substance. Ice melts at 32°F. and water freezes at the same temperature. When 144 B.T.U. are added to one pound of ice at 32°F. it becomes one pound of water at 32°F., and when one pound of water at 32°F. freezes it gives out 144 B.T.U.

Artificial Cold. Every pound of ice which melts takes 144 B.T.U. from surrounding bodies. When ice and foods are enclosed in a box with heat insulating walls, as in a refrigerator, the foods supply the heat which melts the ice; they are cooled by this loss of heat. If the hand is wet with a volatile liquid, as ether or gasoline, and moved in the air, the liquid quickly evaporates and gives a sensation of cold. This principle of cooling is employed in home electric refrigerators. When compressed, some gases as sulphur dioxide and methyl chloride, for example, become liquid and give out heat. This heat is liberated in a *condenser* outside the refrigerator. The liquid then passes from the condenser to the *expansion coils* in the refrigerator; here the liquid *changes to a* gas and *expands*. Both processes absorb heat. In this way the refrigerator is cooled. The expansion coil is connected with a pump which draws the gas out and compresses it again. The pump is driven by means of an electric motor.

Artificial cold is produced on a much larger scale for cold storage warehouses, ice making and indoor skating rinks. The principle of cooling is the same as in the home electric refrigerator, but ammonia is used inside the circulating pipes. The gas is compressed to a liquid in the condenser and the heat removed, often by running water. The expansion pipe is sometimes surrounded by brine in which cans of water are frozen for the purpose of producing ice. The cold brine itself may be pumped through pipes which pass around the walls of rooms or show cases which are kept cool. Thermostats automatically control the degree of cold so that a room may be kept at any desired low temperature.

MECHANICS

Mechanics is the science that treats of force and its effects. A *force* is a push or a pull. Whenever force is applied there are two actions equal and opposite in direction. All kinds of matter have four important general properties: *inertia, gravitation, capacity for carrying energy* and *elasticity*.

Inertia. Bodies at rest remain at rest until acted upon by some force great enough to move them. Bodies in motion continue to move with uniform motion unless acted upon by some outside force. The tendency of a body at rest to remain at rest is called *inertia*, and the tendency of a moving body to continue in a state of motion is *inertia of motion*.

A ball rolled over the floor soon stops. A spinning top soon stops. Why? Frictional force stops them. The friction between any two bodies moving in contact opposes the motion. The wheel of an inverted bicycle once set into motion rotates a long time. The friction has been reduced at the axle by the use of greased ball bearings. Roller bearings in the automobile wheel axle accomplish the same purpose. If the friction at the axis and the friction of the air against the wheel could be entirely removed, the wheel once set into motion would never stop. The earth rotates on an imaginary axis, and moves through space without frictional force. We, therefore, see no reason as far as opposition by friction is concerned, why it will ever stop rotating on its axis once in twenty-four hours, thus giving us day and night, or why it should ever stop revolving around the sun once a year, thereby giving us our four seasons.

Gravitation. Every particle of matter in the universe attracts every other particle with a force equal to the product of their masses and inversely as the square of the distance between them. We are particularly interested in the application of this law to the earth. The attraction of the earth for bodies at or near its surface is called *gravity*. The measure of gravity is *weight*. It is the weight of water that gives it its buoyant force on boats, and the weight of air that gives it its buoyant force to support balloons and airships. There is a point in a body called its *center of gravity*. The body acts just as it would if all the weight of the body were concentrated at that one point. A line from the center of gravity of a body to the center of the earth must always pass within the base of support of the body, or it will tip over.

Capacity for Carrying Energy. Mechanical energy is of two kinds, *kinetic* and *potential*. Kinetic energy is the energy of motion. Potential energy is the energy stored in matter by its advantageous position. When doing work may be one of three types, (1) gravity—lifting a body to a higher elevation; (2) friction—moving a body in contact with another so that surfaces of the two rub together; (3) inertia—starting a body from rest, or stopping a moving body. The English unit of work is the foot pound which is equal to the work done when a resistance of one pound is overcome through a distance of one foot. One horse power equals 33,000 foot pounds a minute.

Elasticity. Elasticity is the ability of matter to recover its original size and shape when the force which distorts or compresses it has been removed. The elastic limit is the point beyond which the body which has been distorted will not return to its original shape and size.

Engineers must plan their bridges so that no loads will distort the steel beams beyond the elastic limit. The elastic power of compressed steam must be understood by the man who designs a new steam engine. Liquids can be compressed very little, and because of this fact, water, glycerine and other liquids are used in machines to produce tremendous pressures. They are used also in hydraulic elevators and in hydraulic brakes of some automobiles. Gases are easily compressed. Each time the pressure is doubled, the volume is halved. One thousand cubic feet of air compressed to 100 cubic feet will exert a pressure of 147 pounds per square inch. Because of its elasticity, compressed air expands when pressure on it is removed. It is used to do work in many ways, as in air brakes, air blasting and road drills.

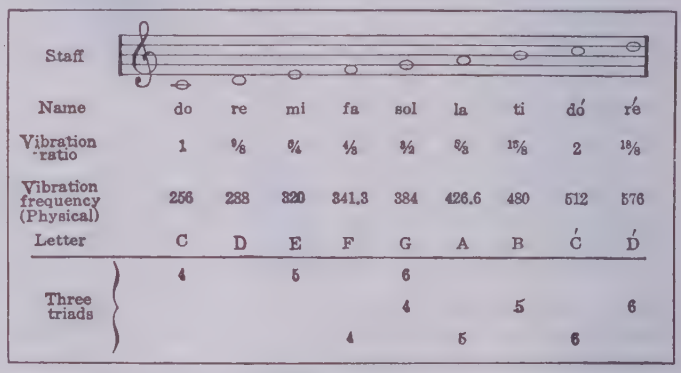
desired, this potential energy can be released, and an equivalent amount of kinetic energy will result. A moving cannon ball strikes a building; the waves of the ocean beat against the shore, and falling water drives a waterwheel. In all of these examples a moving body does work, and they illustrate the utilization of kinetic energy. Water held at a high elevation, a wound spring in a watch or clock, and compressed air illustrate matter in a position of advantage. They have stored energy which can be released at will to do work. The resistance which is overcome in

Two upper diagrams on this page, upper diagram on p. 951, illustrations on p. 952 and diagram on p. 956 from Whitman's *Household Physics* [Wiley].



SOUND

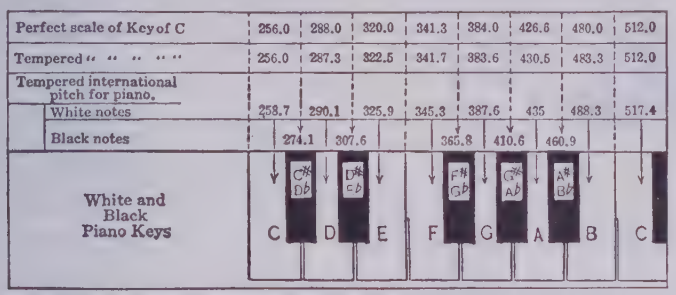
A body vibrating between 16 and 40,000 times a second in an elastic medium such as air causes audible waves of the same frequency as those of the vibrating body. These waves are spherical and rapidly diminish in intensity. When these waves come to a person's eardrum, they cause it to vibrate.

Sound Waves in Air

Sound waves are spherical in form and consist of alternate bands of condensed and rarefied air.

The Musical Scale

The vibration rates given above are the standard ones of the physicist. Those used by the musician are slightly different.



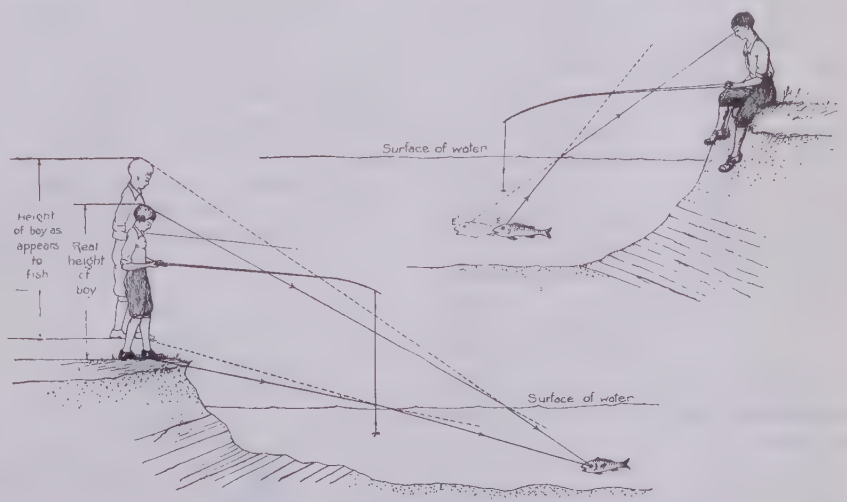
The bones in the middle ear carry the impulses on to the inner ear where the nerves take up the message and carry it to the brain. The person then receives the sensation of sound. Three important characteristics of sound are *intensity*, *pitch* and *quality*.

Intensity or Loudness of Sound. By striking the piano key harder, the wire is made to vibrate through a wider space. This increases the loudness. A sounding tuning fork held with the tip of the handle upon a piano cover or a table, forces a large surface into vibration and this makes the sound louder. A sounding body held at the mouth of a hollow cylinder will be reënforced when the length of the air column is right. The cavity of the mouth acts as a resonant chamber to increase the loudness of a Jew's-harp.

Pitch. Perhaps you have a pitch pipe which gives you a certain musical note. Every musical note is due to a definite number of vibrations per second. High, shrill notes have many vibrations and low, bass notes have few vibrations per second. The frequency of vibration determines the pitch of a sound.

Quality. You easily distinguish between a sound coming from a piano, a violin and the human voice even though they all have the same number of vibrations per second and are of the same loudness. This is possible because they differ in quality. The mingling of overtones with the fundamental tone changes the wave form, and makes it complex without altering its frequency. The overtones may be produced in stringed instruments by a wire vibrating in segments at the same time that it vibrates as a whole. In the voice, the resonant air chambers may be changed and thus change the wave form.

Stringed Instruments. The natural rate of vibration of a wire depends upon length, thickness and tension. Just as a short pendulum swings faster than a long one, so a short wire vibrates more times a second than a long one of the same diameter and material. Halving the length doubles the number of vibrations and raises the pitch one octave. The thicker vocal cords of a man give lower tones than the more delicate vocal cords of a woman. By virtue of this she can produce the higher and shriller tones. The piano tuner makes a string give a higher note when he increases its tension. In order to lower its pitch, he loosens it or gives it less tension.



The Tempered Scale

This is probably what you have in your piano. By equalizing the vibration interval between adjacent notes, music in different keys will be played.

The C on the line above the bass clef is the same as the C on the line below the treble clef. It is therefore called "middle C." In the international pitch used in music, middle A has 435 vibrations per second, and middle C has 261 vibrations per second. The ear recognizes sounds as harmonious if their frequencies are in the ratio of 4:5:6 (major triad). There are three major triads C-E-G, F-A-c, and G-B-d. These give the basis for building the tones of the musical scale called the *diatonic* scale. The physicist uses a tuning fork of 256 vibrations per second as his standard for middle C. A piano, tuned with middle C having 256 vibrations per second and other notes in proper ratio, will produce harmonious music; but it will be of lower pitch than that commonly used by musicians.

To obtain a succession of notes of equal intervals on the piano, five black notes are added in proper places in each octave between the white keys, thus giving twelve steps between C and c. This is called the *chromatic* scale. In tuning a piano, the interval between any two notes is made the same. This varies a little from the values given in the diatonic scale, but not enough to make a noticeable discord with a person who sings or plays a violin in the true diatonic scale. The piano tuned to equal intervals is using the *equal temperament* scale. The piano and harp have a wire for each note. Other instruments, such as the violin, banjo, cello and mandolin, have few strings; but by fingering, each string may be made to produce many notes of different pitch.

Wind Instruments. The organ pipe and tin whistle are two of the simplest wind instruments. Air is set into vibration as it moves across the sharp edge of the opening, and the tube increases the sound by the principle of resonance. If the outer end of the pipe is closed, the pitch is an octave lower than when it is open. In the trombone, a sliding tube changes the length of the air column. Lip vibrations produce the sound in the bugle and cornet. In the cornet there are three extra loops of pipe which can be added by pressing a key, but the cornetist depends largely upon changing the shape of his lips and the wind pressure to make overtone vibrations in producing additional notes. In the bugle it is the air pressure and lip action which cause overtones that make different notes possible, since there is no way of changing the length of the vibrating air column. The clarinet and saxophone have a vibrating reed in the mouthpiece; but in them, as in the flute, different notes are produced by varying the length of the air column. By opening holes in different places along the tube, the effective length of the air column is changed.

Refraction of Light

Refraction causes an apparent displacement of the fish as seen by the boy (E, the actual fish; E′, as the fish appears to the boy). Refraction causes the boy as seen by the fish to appear taller than he really is.

LIGHT

Luminous bodies like the sun, stars, electric lights and burning candles give out light of their own. *Non-luminous* bodies like the earth, stones, trees and chairs are visible only when they receive light and reflect it to our eyes. It is a generally accepted theory that light is carried as waves in the ether. Light travels 186,000 miles a second. Light, just leaving the sun now, will reach the earth in eight minutes.

Three things may happen to light when it comes to a body of matter. It may be *reflected*, *transmitted* or *absorbed*. Usually two of these occur and, in the case of transparent bodies, all three are involved.

Reflection. When light goes from your face to a mirror and comes back to your eyes, you see an image of your face. This cannot happen in a dark room. There must be light which your face can reflect. Then the mirror reflects some of the light it receives from your face.

A smooth surface reflects a beam of light in another beam, but a rough surface scatters or diffuses it. Surfaces which diffuse light are better in our homes and books. A smooth page often makes a glare which is harmful to the eyes. Fewer rays of light are reflected from the surface of glass when they are perpendicular to it than when they are very oblique.

Transmission. Bodies are called transparent (as clear glass), translucent (as frosted glass) or opaque (as wood), depending upon their action in transmitting light. When a transparent body transmits light, the light may pass straight through or it may bend according to the laws of refraction. A body may be transparent to certain rays and opaque to others, as in the case of colored glass.

Refraction. Refraction is the bending of rays of light upon passing from one transparent medium to another of different density. Rays perpendicular to the surface between the media are not bent, but all others are. The bending is caused by the fact that matter slows up the light beam. Owing to refraction, a stream looks shallower than it really is, and objects partly in and partly out of water may appear bent, while in reality they are straight. The illustration shows how bending of rays of light, in passing from water to air and from air to water, causes deception. To the boy fishing, the ray of light from E seems nearer the surface of the water and to start from E′. To the fish the boy looks taller than he really is.

Lenses. When glass is made with rounded surfaces, thicker in the middle than at the

edges, it is called a *convex lens*. It has the power, through refraction, to bring rays of light to a point as in a burning glass, to make images of objects on screens as in the camera, to aid vision as in our spectacles, and to magnify bodies as in the reading glass and in the microscope. A *concave lens* is thinner in the middle than at the edge. It will not make a real image; but an unreal image, smaller than the object, can be seen by looking through the glass at the object.

Early Development of Artificial Lighting
The evolution of artificial lighting from the pitch knot to the kerosene lamp covered a period of 6,000 years.

Absorption. When light energy is absorbed by matter it makes the molecules vibrate with greater energy, thus increasing the temperature of the body. White reflects the greater part of light it receives, while black absorbs the greater part. Selective absorption results in color.

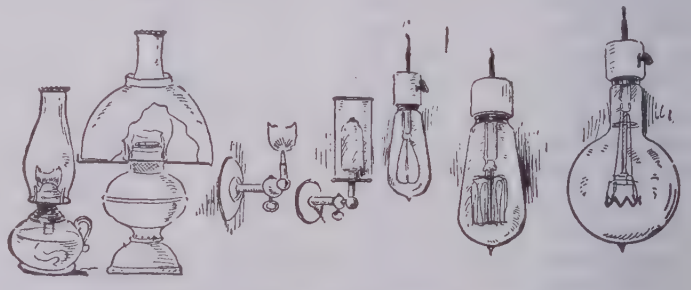
Color. When a beam of sunlight enters a triangular glass prism at a large angle of incidence, a band of *spectrum colors* can be produced upon a white screen. These spectrum colors—red, orange, yellow, green, blue, violet—were all present in the white light from the sun, but were separated by refraction in the prism. Color is a property of light determined by wave length. The wave length of red light is 0.000068 cm., and of violet, 0.000042 cm. The wave lengths of other colors lie between these extremes. When the material in a body absorbs all the light rays except those which have the wave length of red, we say the body is red. Red glass in our windows allows only the red rays to enter. A dress which is blue in daylight will appear black in a room in which light enters only through red glass.

Color Nomenclature. Any two colors which, when mixed, produce a neutral gray, are *complementary colors*. The following pairs are complementary: violet and yellow, blue and orange, green and red. The dominating spectrum color in any mixture is called its *hue*. The *intensity* of any color is softened by mixing a little of its complement with it. The *value* of a color is modified by mixing it with white or black. With black, a *shade* results; but with white, a *tint* is produced. Yellow, green and blue and their tints are called *cool colors*, while violet, red and orange and shades of them are *warm colors*. Any hue may be mixed to indicate both the predominant and the modifying color as well. For example, a little green added to blue gives a green-blue, but a little blue added to green gives a blue-green. Any color appears brighter against a black background and darker against a white background. Complementary colors all harmonize. They also give the strongest contrast.

Mixing Light and Mixing Pigments. Red, green and bluish-violet light can be mixed in proportions to produce white light. By varying the amount of them, any other color can be produced. Since the other colors can be produced from these, they are called the three *primary colors*. Pigments of paints show the color, due to the wave length of rays they reflect from white light, all other colors being absorbed.

The three primary pigments—peacock blue, yellow and crimson (orange red)—seen in white light are complements of the three primary colors. Since the color of the pigments is due to subtracting colors, the mixture of the three will absorb all light and produce black. But the mixture of two of them will produce another color; for example, the blue pigments reflect some green with the blue, but they absorb all yellow. The yellow pigments reflect some green with the yellow, but absorb all blue; hence, when yellow and blue pigments are mixed, all green which is reflected by both is the result. By this principle different colors are produced by various combinations of the primary pigments.

Color Printing. Three photographs are taken of a colored object through three gelatin filters, each stained with one of the three primary colors. Three plates for printing are made from these photographs. The prints are carefully placed so that they will all register on exactly the same spot on a piece of white paper where the print is to be made. Each plate prints a different color; the inks used have the colors of the three primary pigments. In the process of printing, the three plates superimpose one color on another in such amounts that the original colors of the object are reproduced.



Ultra-violet Rays. Just as the sun sends out waves (heat waves) longer than those which are visible, so it also sends out invisible waves at the end of the spectrum. These rays, just a little shorter than those which produce violet light, are called the *ultra-violet rays*. These are abundant in sunlight and are responsible for tanning our skin, for sunburns, for chemical activity in plants and in photography. They have a curative power when properly used. Quartz glass and some special trade glasses transmit much more of the ultra-violet rays than ordinary glass does. The ultra-violet rays can be produced artificially.

ELECTRICITY

Electricity is a form of energy which can be passed over wires to light our lamps, heat our ranges and turn machinery. Or, electricity may charge bodies so that they will attract or repel other bodies. Franklin showed that electricity is the same identical form of energy that accumulates at times in the clouds and produces lightning.

For many years scientists have said, "We know what electricity can do, but we do not know what it is." Recent advances in scientific knowledge have dispelled much of the mystery that has surrounded electricity for so long a time. The central nucleus of all atoms consists of *protons*, and about these are other bodies, called *electrons*. The electrons revolve in orbits about the central nucleus much as planets revolve around the sun. Electrons are negative electricity, and protons are positive electricity. (See article on "Chemistry" for more details of electrons and protons in the atom.)

The name "electricity" is derived from the Greek word *electron*, meaning "amber." When the ancient Greeks rubbed amber with wool, some of the electrons moved from the wool to the amber, giving it an excess of electrons. The amber thus became *negatively electrified* and would attract light bodies. The wool, having lost electrons, had an excess of protons and became *positively electrified*. Friction was the only artificial source of electricity employed until Galvani, near the end of the eighteenth century, accidentally obtained it by the contact of two metals with the moist leg of a frog. Volta developed Galvani's discovery, and in 1800 invented the first *galvanic* or *voltaic* battery by which a *current of electricity* was produced.

Recent Development in Artificial Lighting
Within a period of fifty years the kerosene lamp has been followed by gas, the gas mantle and the various types of incandescent electric lamps.

There are two types of electrical action: attraction and repulsion of electric charges *at rest*, called *electrostatic*, and attraction and repulsion resulting from the magnetic effect of electricity *in motion* or current electricity, called *electro-dynamic action*.

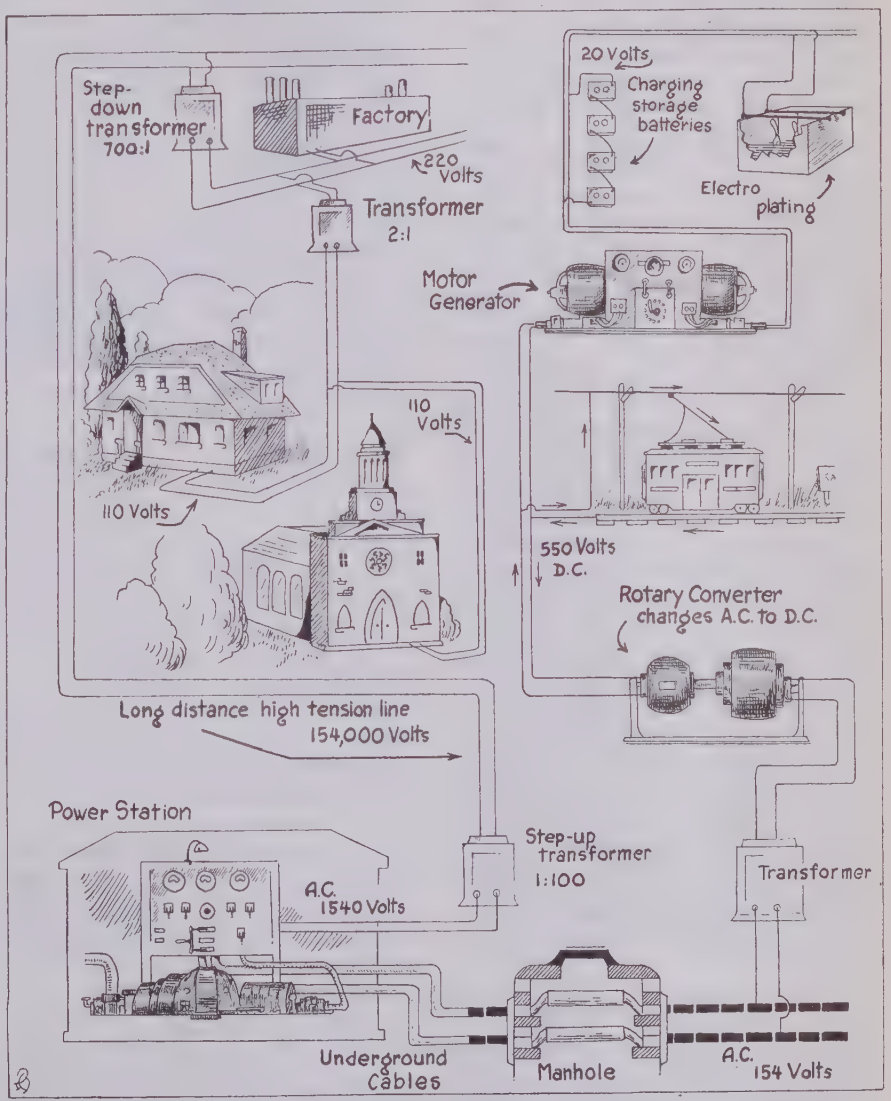
Conductors and Nonconductors. When a metal rod is held in the hand and rubbed with wool, no electric charge is detected on the metal. If the metal rod is held in the hand which is covered with a heavy rubber glove and then rubbed with wool, it will have an electric charge. In the first case electricity was produced, but was conducted away into the hand and body. In the second case the electricity remained on the metal, because rubber does not conduct electricity.

Depending upon their ability to conduct electricity, materials are classified as conductors, poor conductors and nonconductors. Nonconductors are also called insulators. The following table shows the relative conducting power of common substances:

Good Conductors	*Poor Conductors*	*Insulators*
metals	moist air	dry air
"lead" in pencil (graphite)	pure water	rubber
carbon in battery	kerosene	mica
water solution of acid, base and salt	wood	bakelite
	paper	paraffin
	cotton	porcelain
	wool	

Examine the crossbars on poles along the streets which support electric wires. Can you find insulators? Heavy insulators must be used in high tension circuits. In your home, you find insulators as the base of switches, light sockets and fuse blocks. Wire for the powerful electric light current is insulated by covering with rubber, several layers of cotton, and waterproof material outside of all. For an electric bell, a double cotton cover is sufficient insulation. The production and transmission of the electric current would not be possible were it not for the fact that some materials are conductors and others are insulators.

Electrostatics. All neutral bodies have equal numbers of electrons and protons. When this balance is disturbed as, for example, by friction between two unlike bodies, an excess of electrons on one gives it a negative charge, and an excess of protons on the other gives it a positive charge. If these charged bodies are conductors or are conducting materials which are insulated, the charges remain at rest and are called *static charges*. Glass rubbed with silk becomes positively charged, but rubber rubbed with silk, wool or fur becomes negatively charged. Oppositely charged bodies attract each other, but bodies with like charges repel. The force of attraction or repulsion varies directly as the product of the charges, but inversely as the square of the distance between them.



$$F \propto \frac{\text{charge 1} \times \text{charge 2}}{\text{distance}^2}$$

When a charged body is brought near a neutral body it causes a separation of electrons. If the charging body is positive it attracts electrons to the side near it; but if the charging body is negative it repels them to the distant side. On removal of the charging body the electrons go back and make the body neutral again. By grounding a body which is under the influence of a negative charge, the earth receives electrons; and by breaking the earth connection before removing the negative body, the return of electrons is prevented. The body thus becomes permanently electrified. This process is called *induction*.

Lightning. Two insulated conductors may be so heavily charged respectively with positive and negative electricity that when they are brought near each other they overcome the high resistance of the air and an electric spark passes between them. Since induction may produce an opposite charge in the side of a body near a charged body, a discharge may also occur between a charged body and a neutral body. This action, which is shown on a small scale in the laboratory, occurs on a huge scale in nature.

Under certain conditions, raindrops falling through a strong ascending current of air are broken into a spray. The fine particles receive a negative charge, and the larger particles a positive charge, of electricity. The positively charged raindrops, being heavier than the finer, separate and fall to the earth, thus removing the positive electricity from the atmosphere. The negatively charged spray may gather in a cloud. The continued accumulation of electricity produces such heavy charges that the resistance of the air between cloud and earth breaks down, and a lightning flash results. It is possible for the positively charged particles also to form a positively charged cloud, and lightning may then pass from one cloud to another, but this is rare. Most of our lightning is between negatively charged clouds and the earth.

Lightning heats and expands the air. Upon cooling, a partial vacuum results, and the meeting of molecules of air pushed into the vacuum by atmospheric pressure produces the sound we call thunder. Light travels practically instantaneously, while sound

Electricity at Work

Showing some of the uses of electricity for light and power, and illustrating some of the changes incident to the transmission and varied uses of electricity.

travels about one-fifth of a mile a second. If we count the seconds between the flash and the thunder coming from it, we can tell how far away the lightning is; allow five seconds to the mile. Bodies extending above the earth shorten the distance for lightning to travel through the air to reach the earth, and so are common targets for the lightning. Lightning rods, extending above our buildings and reaching down deep enough into the earth to be always in moist earth, allow a discharge between clouds and earth without using the buildings as part of the discharge path. Man-made lightning, produced by discharging electricity at over a million volts, is used in laboratory studies of the nature and control of lightning.

Electricity and Magnetism. In 1819, Oersted discovered that a wire carrying a current of electricity was surrounded by a magnetic field. Two parallel wires carrying currents will be attracted if they carry current in the same direction, but will repel each other if the current flows in opposite directions. In 1831, Joseph Henry wound insulated wire around a soft iron core and produced the first electro-magnet made in America. By control of the electric current, it is possible through the magnetic force to ring bells, operate telegraph and telephone instruments, drive motors, and lift tons of iron or steel by means of powerful lifting magnets. In 1831, Faraday, in England, discovered that a closed coil of wire, if moved so that it cut lines of magnetic force, would have a current of electricity generated in it. The use of this principle in generators in our power stations is responsible for the great development of electricity today.

Electric Units. The *ampere* is the amount of current which is required to deposit silver at the rate of 0.001118 gram per second. The resistance offered by any conductor to the flow of an electric current is measured in ohms. An *ohm* is equal to the resistance offered by 1,000 feet of No. 10 copper wire. In order to drive electricity along a conductor, there must be electromotive force or electric pressure. A *volt* is that electromotive force required to drive a current of one ampere through a resistance of one ohm. The relation of these three units is expressed in Ohm's Law, as follows:

$$\text{I (amperes)} = \frac{\text{E (volts)}}{\text{R (ohms)}}$$

If you find by test with an ammeter that one dry cell (voltage is 1.5) sends .5 amperes through an electric bell, you find the resistance of the wire in the bell is three ohms as follows:

$$.5 = \frac{1.5}{x}, \text{ hence } x = 3 \text{ ohms.}$$

The unit of electric power is the *watt*. It is the amount of power developed by a current of one ampere and electromotive force of one volt.

volts x amperes = watts.

One horsepower equals 746 watts. A kilowatt-hour equals 1,000 watts for one hour. If you pay 10c a kilowatt-hour for electricity and burn five 100-watt lamps for four hours the cost of lighting will be:

$$\frac{5 \times 100}{1000} \times 4 \times .10 = .20 \text{ or } 20\text{c.}$$

The Generator. By far the most important electrical machine is the generator (dynamo). In one type of commercial generator a rotor is rotated inside a stator. The rotor, or armature, has a number of electro-magnetic poles alternating north and south. A direct current carried through brushes to rings connecting with the ends of the wire of the rotor produces the magnetic fields which are moved so that the coils of wire on the iron ring of the stator cut the lines of force. Since each coil receives lines of force alternately from north and south poles, the current generated will be an alternate current.

Transformers. When two coils of wire have one iron core in common, and an alternate current is sent into one coil, called the *primary* coil, the lines of force coming to and going from the other, or *secondary* coil, produce a series of currents in it by the principles of induction. The device is called a *transformer*. The voltage in the two coils varies directly as the number of turns of wire in the two coils; thus the voltage will be raised if the secondary has more turns of wire than the primary, but will be lowered if the secondary has less turns than the primary.

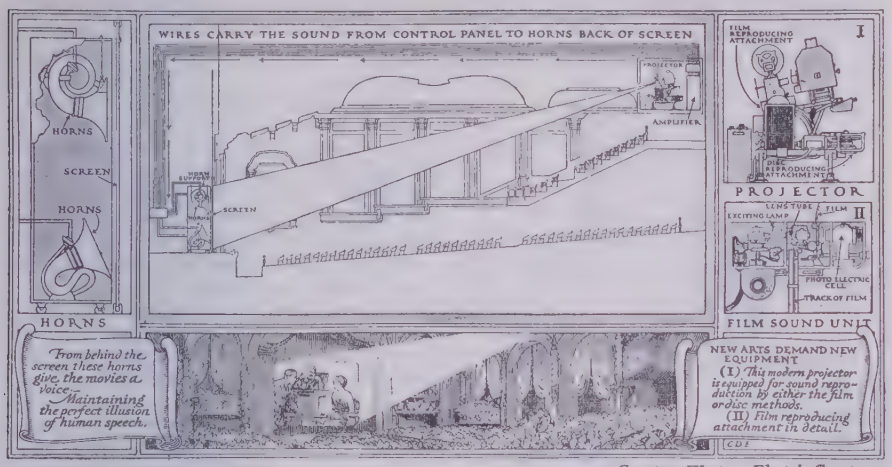
The number of amperes will change inversely as the volts, so that the watts in the primary always equal the watts in the secondary. Electricity can be transmitted at high voltage and low amperage with less loss of energy than at low voltage and high amperage. The heat effect of an electrical current varies as the square of the current. There is some heating in all conductors; but if the current is doubled, the heat developed is four times as much. To prevent this loss in heat, long distance transmission is at a high voltage. This can be stepped down to low voltage where it is to be used.

Sources of Electricity. There are two important sources of electricity; namely, chemical energy and mechanical energy. A chemical cell requires two plates of unlike material and an electrolyte. In one type of wet cell, ammonium chloride in water solution is the electrolyte, and the two plates are carbon and zinc. Mechanical energy is used to rotate coils of wire in a dynamo in such a way that the coils cut lines of magnetic force. The mechanical energy is derived from falling water, from steam engines and, to a limited extent, from gas and oil engines.

Chemical Cells. The dry cell used for ringing door bells, in flash lamps, and as the B-battery for the battery operated radio, have two plates, zinc and carbon, separated by a paste which contains ammonium chloride. The carbon pole is positive and the zinc, negative. Each cell has a pressure of 1.5 volts and, when new, should give 27 or more amperes of current on short circuit.

Each cell of the storage battery contains positive lead plates having perforations filled with lead peroxide, and negative plates filled with gray spongy lead. The electrolyte is a solution of sulphuric acid in distilled water. When the battery is used, chemical action causes some of the oxygen to be transferred to the spongy lead. When both plates contain about the same amount of oxygen, no more current will flow. It is recharged by passing a current into it in the opposite direction from that produced by the cell. This removes the oxygen from the spongy lead, and adds it to the positive plate. The storage cell does not really "store" electricity. The electricity put into it causes chemical action which will reverse itself and produce electricity. The ordinary lead cell gives two volts. The capacity is indicated as *100 ampere hours*, which means that a battery of this rating will give one ampere of current for 100 hours, 4 amperes for 25 hours, or 25 amperes for 4 hours. The battery should not fall below 1,200, hydrometer test, before recharging it. It reads, 1,280 to 1,300 when fully charged and 1,140 when "empty."

Hydroelectric Development. Recent years have seen much activity in developing great water power projects. At Niagara, at Muscle Shoals and at Conowingo, electric plants are already using hundreds of thousands of horse power of mechanical energy derived from falling water. This is changed into electric energy, some of which is carried hundreds of miles away for use. The most efficient type of water wheel is the water turbine. Water flows through a penstock, at the bottom of which the turbine is placed. The turbine is on a vertical shaft which extends to the power house above, where the rotor of a generator is turned by this same shaft.



The Conowingo power house is twelve miles above the mouth of the Susquehanna River. The seven 54,000 horse power water turbines already installed deliver on an average about 1,250,000,000 kilowatt-hours of energy annually to Philadelphia. During low water and for "peak" loads at other times, steam-produced electricity will be used. The installed capacity at Conowingo is exceeded only by that at Niagara. About 13,000,000 horse power have been developed in the United States. This is one-third of the total amount which is available ninety per cent of the time.

Radio. Radio includes what has sometimes been called "wireless" telegraphy, radio broadcasting and receiving, and the radio telephone. Marconi developed the first practical system of radio telegraphy. In 1907 Lee de Forest added a grid to the two-element vacuum tube and thereby laid the foundation for radio broadcasting and the radio telephone. (See special article on "Radio.")

The Photoelectric Cell. The photoelectric cell, popularly called the "electric eye," is the life of many new electrical devices. The bulb of the cell has an opaque covering, except for a small window for light to enter. On the inside, and opposite the opening, is a small piece of bright potassium metal very sensitive to light. One wire is connected to this metal; the other terminal is joined to a ring of wire in the center of the bulb. When a beam of light passes through the opening and strikes upon the light-sensitive potassium, the potassium emits electrons, and a current thus set up may be used in many ways. It may operate a traffic signal when it receives light from an automobile headlight. It may automatically turn the lights on in a room when it is too dark. It may serve as a counter, making a record of each interruption in the beam of light; it will sort out materials according to color or imperfection, or give

an alarm if smoke from fire is produced in its neighborhood. It is also an essential part of devices used in radio television.

The Telephone. In a telephone, the transmitter, which is a sound-sensitive instrument (an electric ear), receives the sound through them, and the current varies according to the sound produced in front of the transmitting microphones. The sound record may be made on the edge of the same film which has the picture, or it may be made upon a separate film. The sound film, when

Courtesy Western Electric Company

Making the Moving Pictures Talk

waves and converts them through changes in resistance into electric impulses which may travel long distances to the other end of the telephone circuit. When these electric impulses enter the receiver, they produce (by electro-mechanic means) sound waves, which are duplicates of those at the other end of the line.

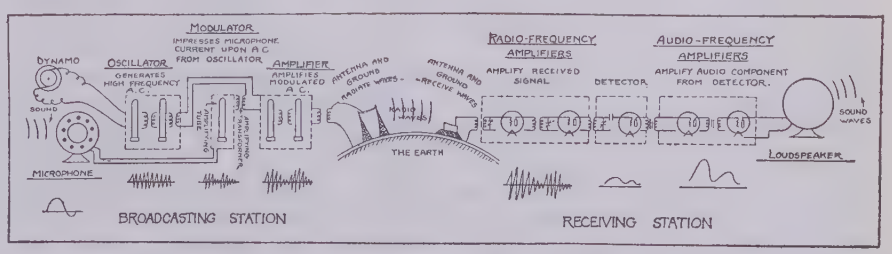
Television. The steps employed in television are very similar to those used in the telephone. At the sending end there is a photoelectric cell (a light-sensitive instrument, or electric eye), which receives light from the object whose image is to be transmitted. The photoelectric cell converts the energy of the light received into electric impulses which vary in intensity in proportion to the intensity of light. At the receiving end, an instrument is employed which is capable of converting these electric impulses back into light in such a way that an image is produced which duplicates the object at the sending end.

Sound Pictures. Sound pictures, popularly called "talking movies," combine two of our modern miracles of science—the reproduction of sound that may effect the sense of hearing, and the reproduction of an image that may effect the sense of sight. A scene—words and action—may be produced, and both the picture and the sound recorded on a moving picture film. Duplicates of this film can be made so that people in a thousand different towns and cities are able to witness the scene and hear the conversation, music or other sounds which exactly duplicate those at the place of original production.

In one method of recording sound upon the moving picture film, a beam of light of constant intensity but of varying width plays upon a narrow strip of the film. The light comes to the film through a narrow opening between two parallel wires which are between two magnets. The wires move to open or close the slit according to the current passing developed, has a series of dark lines alternating with light lines of varying width. The light which can pass through the sound film will vary according to the width of these lines. In projecting from a sound film, use is made of the photoelectric cell. Light which passes through the film is received by the photoelectric cell which passes an electric current proportional to the light which it receives. This fluctuating current is amplified and taken to the loud speakers which reproduce the original sound. When the sound film is separate from the picture film, the motion of the two must be carefully synchronized. For use in the theaters, four or more loud speakers are commonly used.

RADIO

THE last few years of the nineteenth century brought with them a new means of communication—radio. Guglielmo Marconi, an Italian, had demonstrated that signals could be sent over short distances without wires connecting the two points, as in the case of ordinary telegraph systems. His invention was immediately termed "wireless," though in the past few years it has come to be called "radio," a term which applies both to radiotelegraphy and radiotelephony.



Marconi's success led other experimenters to enter the field, with the result that greater and greater distances were covered. The new system gradually emerged from the experimental stage and became practical. By 1912 it had proved its value as a means of communication between ships and from ship to shore. Vessels of several nations were equipped with radio apparatus which, in many cases, was a big factor in bringing assistance in case of disaster at sea.

Transatlantic wireless was established about this time and became a competitor with the undersea cable telegraph. Scientists were also working on the problem of transmitting the voice by wireless and were achieving some success.

Wireless and the World War. With the coming of the World War, all the nations involved were quick to see the great importance of radio. During the years of the conflict, its development was remarkable and many new applications were found. Naval vessels and fleets depended upon this means of communication with their bases. It was found that submarines could be reached by radio while running submerged. Aircraft also were enabled to maintain contact with the ground, thus permitting their use in locating objects and forces to be attacked by artillery fire and effectively directing that fire. One important wartime development that has come into importance in peace times is the "radio beacon," or "radio compass," which permits a ship or airplane to determine its position by means of radio signals.

Development of Radiotelephony. During the war great strides were made in transmitting speech by wireless and further development in the following years soon found a new application in broadcasting which, as we know it today, began in 1920. The transmission of programs to the public met with increasing favor and now represents a service which has become so valuable that many would find it hard to do without.

Physics teaches that sound is transmitted through the air by waves at a velocity of approximately 1,000 feet per second. The wave that makes one particular sound is of a definite size or length. Thus if we strike "Middle C" on a piano, 256 waves are sent out in one second, the first of which would be heard by an observer 1,000 feet away one second after the note was struck. If we

How the Radio Program is Sent and Received

struck "C" one octave higher, 512 waves would start traveling outward from the piano string with the same speed as those from the "Middle C," and the first one would reach the observer stationed 1,000 feet away in exactly the same time—one second. In one case we have sent out 256 waves in one second and in the other, 512. Since they both travel the same distance in the same time, the

"Middle C" waves must be twice as long as those of the higher "C." We can express this mathematically as follows:

$V = N \times L$

where V = velocity of the waves
N = the number of waves or "cycles" per second
L = the length of one wave

This expression may be arranged in two other ways:

$$(a)\ N = \frac{V}{L}$$

$$(b)\ L = \frac{V}{N}$$

(a) shows that, since the velocity of sound is constant for certain conditions, if we know the length of any sound wave we can tell the number of waves per second or the frequency of that particular sound. (b) shows that if we know the frequency of any sound we can tell the length of one of its waves.

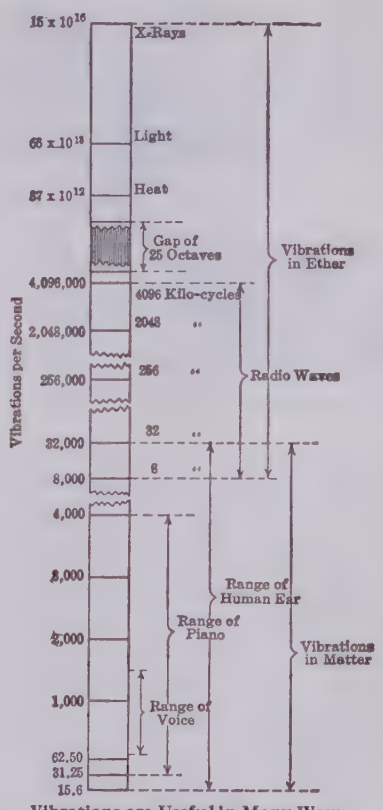
The human ear recognizes, as sounds, waves of frequencies of from approximately 16 to 40,000 cycles per second. Frequencies within this range are called the "audio frequencies."

Radio waves are much the same as sound waves with the important difference that they travel through any space whether there is air in that space or not. They also travel at a speed of 186,000 miles or 300,000,000 meters per second—much faster than sound waves. If we know either the wave length or frequency of one particular radio wave we can find the other just as we do in the case of a sound wave.

Thus, if a radio station has a wave length of 200 meters, its frequency, or the number of waves it sends out in one second, is

$$N = \frac{300,000,000}{200} = 1,500,000 \text{ waves or cycles}$$

per second.



This is usually expressed as 1,500 kilocycles since the prefix "kilo" means "one thousand."

Similarly, if a station has a frequency of 500 kilocycles or 500,000 cycles, its wave length would be

$$L = \frac{300,000,000}{500,000} = 600 \text{ meters.}$$

"Radio frequencies" are those of from about 20,000 to over 300,000,000 cycles per second.

Broadcasting. Let us now examine what happens in sending a program from a broadcasting studio to those who are receiving the program. The artist stands before a microphone which is similar to that used on a telephone. This instrument changes the sound waves into electric waves which represent the singer's voice. These waves are amplified (made stronger) by sending them through audio frequency amplifiers which make use of vacuum tubes of the type found in every radio receiver. The amplified voice waves are then sent along telephone lines to the transmitting station which is usually outside the city in which the studio is located. The transmitter generates waves at some frequency or wave length which has been assigned to it by the government of the country in which it is situated. It generates these waves by means of vacuum tubes which, though often larger and more powerful than those used in radio receivers, operate in much the same manner. These radio frequency waves are often called "carriers," that is, they serve as a means of carrying the audio waves from the transmitter to the receiver. The audio frequency waves from the studio are combined with the carrier, the electrical combination of the two being

Vibrations are Useful in Many Ways

Vibrations in matter give us sound. Vibrations in the ether give us heat, light, ultra-violet rays, the x-rays and radio.

called "modulation"; or the carrier is said to be "modulated." The modulated waves are then sent out into space from an antenna, which is usually a network of wires suspended above the surface of the earth by towers.

When such waves pass a receiving antenna they "induce" in it very small voltage waves—usually no more than a few millionths of a volt—which represent exactly the modulated waves sent out by the transmitter. If the receiver is "tuned" to the wave length of the transmitting station, that is, if its electrical circuits are adjusted so that it responds to waves from that station only—just as, when a given piano key is struck, a corresponding string in another piano in the same room will start to vibrate—these feeble voltages will be accepted by the receiver while waves at any other frequencies will have no effect. The receiver amplifies them, using vacuum tubes for this purpose.

Now it was seen that the transmitter sent out a combination of the radio frequency carrier and the audio frequency wave which represented the singer's voice. Before the signal can be heard the two must be separated in some way. This is done by the "rectifier" or "detector" tube in the receiver which, after separating the two "components," allows the radio frequency—which is above the range of audibility—to be eliminated while the audio frequency wave is sent through an amplifier which makes it sufficiently strong to operate a loud speaker. The loud speaker is nothing more than a very powerful telephone receiver which changes the audio waves into sound waves and sends them around the room. Thus the singer's voice, after a very roundabout trip in which it undergoes many changes, comes from the loud speaker in the same form in which it entered the microphone. In some cases programs sent out from one station have been received and sent out from another station thousands of miles away with very satisfactory results.

Present Day Use of Radiotelegraphy. Although radiotelephony, as used in broadcasting and the transatlantic telephone and a few other services, has reached an advanced stage, it has by no means supplemented radiotelegraphy. Code transmission is still used in the majority of cases where messages are sent and received. "Automatic printers" are frequently used, in which the messages are sent and received on paper tapes at a high rate of speed.

Amateurs and Short Waves. Many boys and men in almost all countries of the world operate private stations which they have constructed themselves at little expense. These are called "amateur stations" and are licensed as such. Their owners have very interesting experiences in communicating—usually by code though occasionally by voice—with similar stations often many thousands of miles away.

During the past few years it has been found that wave lengths below 100 meters offer tremendous possibilities in long distance transmission. These are known as "short waves" and many branches of radio service make use of them. For a given amount of power at the transmitter much greater distances can be covered than by using higher wave lengths, and communication is now (1931) being carried on over wave lengths as low as five meters. It is probable that the next few years will see wave lengths of less than one meter in active use.

Regulation of Radio. Since radio has come into such common use, some means of regulation is necessary to allow it to be used to greatest advantage. The governments of almost all civilized nations have jointly agreed to adhere to certain rules. Thus a given station is licensed by the government of its country to use a certain power and wave length depending on its type of service—that is, whether it is a broadcasting station, a ship station, a radio beacon and so forth—and in this way stations of one type are assigned to certain specified bands of wave lengths. All broadcasting is done on frequencies between 550 and 1,500 kilocycles; ship to shore transmissions on 500 kilocycles and certain other specified frequencies. This eliminates much confusion and allows the maximum number of stations to operate on the available frequencies.

ZOÖLOGY

ZOÖLOGY is the science that treats of animal life. It has a framework of philosophy, but is founded on physics and chemistry. Students of zoölogy have as their aim the analysis and explanation of life, particularly of animal life.

An understanding of the general foundations of zoölogy is necessary for the study of medicine, sanitation, agriculture, sociology, psychology and eugenics.

Characteristics and Tests of Living Objects. Any one can tell, merely by looking at them, which of two given objects is a dog and which is a clod of earth; but it is not always so easy to find the exact differences which distinguish living from non-living objects. The usual tests applied to discover these differences are the following: chemical composition, metabolism, reproduction, irritability and organization. These will be briefly discussed in the order given.

We know that the bodies of animals are made up of relatively few and relatively simple chemical substances, of which the most generally found are: carbon, hydrogen, oxygen, phosphorus, potassium, iodine, nitrogen, sulphur, calcium, iron, magnesium, sodium and chlorine. The most important of these are carbon, hydrogen, oxygen, nitrogen and sulphur, which together make up ninety-nine per cent of the weight of the average animal. When these substances combine to form living matter, the result is called *protoplasm*.

Protoplasm is not a definite chemical compound. Further, it is constantly changing; yet it has a degree of constancy like that of a village from which people are always coming and going, but in spite of this shifting the village keeps the same name and, to a large measure, the same general characteristics.

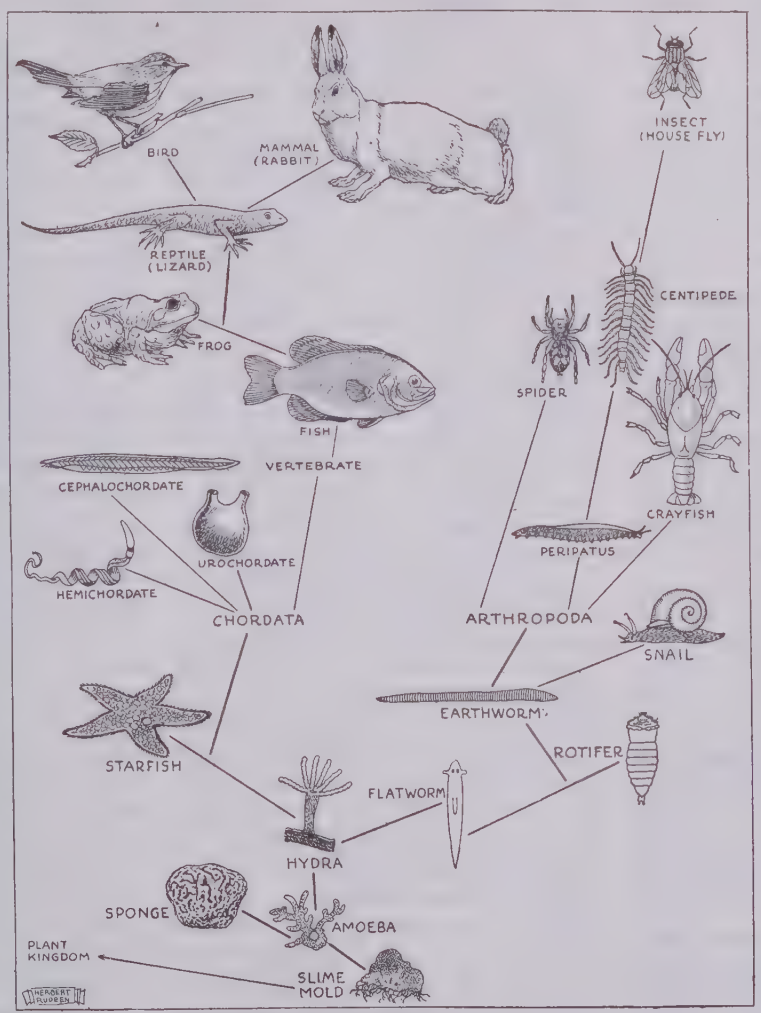
Frequently the combinations making up protoplasm are very complex, even though they are composed of relatively simple and common chemical elements. Thus, muscle tissue is characterized by a very complex chemical structure; but in muscle structure, as well as in the bulk of all other animal tissue, the larger part is nothing but ordinary water. It is astonishing to know that animals with all their wonderful possibilities of growth, movement, memory, intelligence, devotion, suffering and happiness, should have seventy to ninety per cent of their weight composed of nothing more complex than water. Even this brief survey is sufficient to show that we cannot in any certain way, distinguish living from non-living matter by mere chemical analyses.

Metabolism, our next point under consideration, is also found in non-living as well as in living substances. Both types undergo growth and repair—a non-living salt crystal as well as a living animal; and both suffer partial or complete destruction, as when iron rusts or living tissues waste away.

Irritability, too, is a characteristic of both kinds of substances: it is found in dynamite as well as in animals.

Reproduction, which always occurs in living substances, also occurs in many non-living substances. They reproduce by dividing when they become too large, as do clouds under pressure of the wind.

Moreover, though we commonly call living things organisms (because of their organized structure), organization is also definitely seen in the non-living crystals and their like.



We must therefore conclude that there is no one test which will distinguish living substances from all non-living substances. The touchstone which comes nearest to success in doing this is the automatic (self-moving) nature of these several processes which, once begun in living things, may continue to operate automatically for years in the individual animal, or in many races of animals for centuries or geologic ages.

If it is difficult to draw up precise distinctions between living and non-living matter, it is still less possible always to distinguish between plants and animals. Any one can tell a cow from an oak tree; but there are some very simple organisms that are claimed by both botanists and zoölogists, because they show characteristics of both plants and animals. Such organisms are called, by way of compromise, "primitive plant-animals." Some of them the zoölogists call *Mycetozoa* (slime molds), but the botanists speak of the same organisms as *Myxomycetes*. In our chart, which shows the relationships of the animal kingdom, they are placed at the bottom, as an indication of their relatively simple organization.

When one makes even a hasty survey of all animal life, he finds that there are different degrees of complexity that can be readily recognized. It is convenient for our study to arrange animals according to the degree of complexity shown in their organization. At the same time we shall summarize what is at present known concerning the relationships of the different groups.

The evidence for these relationships comes from the study of fossil remains of the animal races; from the study of embryology, which considers the development of the individual animal; and the study of the origin, nature and relations of different body structures. Many facts discovered by these studies have been further confirmed by delicate chemical blood tests of the different animals.

The results of all these studies are sum-

Animal Relationships

Beginning at the bottom, the Slime Mold is a representative of the primitive plant-animals. The Amoeba represents the *Protozoa* which are animals without tissues. The Hydra is a type of the *Coelenterata*; the Flatworm (*Platyhelminthes*), Rotifer (*Trochelminthes*) and Earthworm (*Annelidae*) are representatives of the *Vermes*. The Snail is a type of the *Mollusca*. The *Chordata* and the *Arthropoda* are the other two phyla represented in this chart. Important classes of the present day *Arthropoda* are indicated: the Crayfish (*Crustacea*), Peripatus (*Onychophora*), Centipede (*Myriopoda*), Spider (*Arachnoida*) and House Fly (*Insecta*). In the *Chordata*, the subphyla, *Hemichordata*, *Urochordata*, *Cephalochordata* and *Vertebrata* are shown, the latter by the classes Fish (*Pisces*), Frog (*Amphibia*), Lizard (*Reptilia*), Bird (*Aves*) and Rabbit (*Mammalia*). In more technical accounts many of the lower groups are similarly divided into subphyla and all are subdivided into class, order, family, genus and species.

marized in the chart, "Animal Relationships." The simplest animals are placed at the bottom. Distance from the bottom shows the relative degree of complexity of any group.

This chart represents a somewhat simplified picture of modern opinion concerning the animal kingdom. For example, there are facts which seem to indicate that the *Chordata* are directly related to the worms (represented by the earthworm), but the arrangement of this chart disregards those facts. Moreover, there are certain small groups that have been entirely omitted. One group, the lampshells, or *Brachiopoda*, has characteristics which seem to link it to both main branches; and it may in fact represent another stalk arising from the coelenterates (represented by the hydra), independently of the other and more important branches. Again, the great group of worms, *Vermes*, are nowadays frequently split into several smaller subdivisions. These are noted in the text of this article.

The two main branches of the animal kingdom are distinguished from each other (1) by differences in body development, and (2) in the type of larvae, as the young stages are called. Some of these differences will appear later in the discussion.

CLASSIFICATION AND NATURAL HISTORY

The following brief review of the different sorts of animals, together with the chart, will give a general idea of the diversity or variety of animal life.

Phylum **Protozoa** (primitive animals). There are 8,500 known species of protozoans. These are usually single-celled animals, always lacking tissues. Most of them are microscopic in size, though some are visible to the unaided eye. Four distinct types are recognized.

Subphylum 1—**Rhizopoda** (root-footed) move by means of pseudopodia, or false feet, which are projections from the body that can be extended or retracted as needed. *Amoeba*, one of the simplest and most studied animals, belongs here. Some amoebae are parasitic in man, and one variety produces amoebic dysentery.

Subphylum 2—**Mastigophora** (whip-bearers), or flagellates, move by the vibration of long whip-like flagella. Some have chlorophyll, which is the green coloring matter in plants. Others are colorless. Many are disease-producing parasites causing, among others, African sleeping sickness and syphilis.

Subphylum 3—**Infusoria** (found in infusions) swim by short bristle-like projections called cilia. Some, such as the *Paramecium*, are large enough to be seen with the unaided eye. They are found abundantly in infusions made by steeping common hay in water. After cooling, such an infusion should be seeded with a small amount of pond water containing plant debris, covered and allowed to stand for some days.

Subphylum 4—**Sporozoa** (spore animals) are exclusively parasitic. When adult they lack all organs of locomotion. They produce many diseases. The most widely known human parasite of this group causes malaria. It lives for a part of its lifetime in a certain mosquito, called *Anopheles*, and is transferred to its human host when he is bitten by this mosquito. The best method of control of the parasite is to destroy the breeding places of the mosquito by draining off all standing water or treating it with oil.

The Protozoa have been in existence for an unknown length of time, probably over twice the length of known fossil history. During all this time some have never developed beyond the protozoan stage. Certain Protozoa are highly specialized with little nerve fibrils and small contractile fibrils, like tiny nerves and muscles. Other Protozoa have only generalized protoplasm. They are found everywhere; in the air, in soil, and in both salt and fresh waters.

Phylum **Porifera** (pore bearers). These are the sponges. In the 2,500 species, only one family is found in fresh water; the others all live in the sea. They are classified according to their skeletons, some of which are made of glass, others of limestone, and still others of a silk-like substance. The well-cleaned skeletons of the last-named are the commercial sponges, which grow along tropical coasts. They can be grown from cuttings, like plants.

Phylum **Coelenterata** (body cavity and digestive tract combined). Of these there are 4,200 species, mainly marine, although *Hydra* is widespread in fresh waters. These animals are radially symmetrical, arranged on a cylindrical plan. The alimentary canal has only one opening, which is surrounded by one or more rows of food-gathering tentacles. The body wall is composed of two layers, an outer ectoderm and an inner endoderm. In all the remaining phyla there is a third layer, lying between these two, which is called the mesoderm. Hydroids, jelly fishes, corals, and sea anemones belong in the group of coelenterates. They are of little economic importance, with the exception of the corals, which have added thousands of square miles to the earth's surface. It is generally known that the coral islands of the tropical seas were built up from the skeletons of these little animals; in the United States, the southernmost part of Florida is coral-built.

Phylum **Ctenophora** (comb bearers). This is a marine group of about one hundred species, which resemble jelly fishes and are closely related to them. They possess two openings to the alimentary canal. They are of no economic importance and of little general interest.

Phylum **Vermes** (worms). This is a mixed assemblage of worm-like animals in which we may recognize the following clearly defined groups that many zoölogists regard as separate phyla.

1—*Platyhelminthes* (flatworms) are a group of 4,600 known species that typically have but one opening to the digestive canal. This is located on the lower side and near the center of their flat, ribbon-like bodies. There are marine, freshwater and parasitic forms, divided into three classes, two of which are exclusively parasitic. The parasites include the flukes and the tapeworms. The latter are degenerate parasites that have lost their entire digestive system and, attached to the digestive tract of their host, float there, absorbing the host's food. They may be found parasitic in man, but are much more common in the other vertebrate animals.

2—*Nemertinea* (unerring aim) are a small group of only 400 species. They are flat, like the flatworms, but have two openings to the digestive tract—a mouth and a posterior opening, called the anus. They also have a proboscis which can be thrown out from an opening just above the mouth, and which snaps back into place just as a ball on a rubber cord returns to the hand of the thrower. This aids in collecting the animal's food.

3—*Nemathelminthes* (round worms) are known mainly from their parasitic species. Only 1,500 species are known, including such forms as *Ascaris*, the common round worm found in swine and in man; the hookworm, parasitic in man; and *Trichina*, which is most common in rats, but which may also reach man through underdone pork infested with the *Trichina*. It is estimated that there are 80,000 species parasitic in vertebrates alone, while the number parasitic in invertebrate animals, together with the free-living forms, greatly exceed those found in vertebrates. They seem to be everywhere. Nathan Cobb, the U. S. Department of Agriculture specialist in nematodes, writes: "If all the matter in the universe, except the nematodes, were swept away, our world would still be dimly recognizable, and if, as disembodied spirits, we could then investigate it, we would find its mountains, hills, vales, rivers, lakes and oceans represented by a film of nematodes. The location of towns would be decipherable, since for every massing of human beings there would be a corresponding massing of certain nematodes. Trees would stand out in ghostly rows, representing our streets and highways."

4—*Trochelminthes* (wheel worms) are also called *rotifers* from their most important class. There are 900 species known, limited to fresh water. They are microscopic in size but have many cells. Their name comes from the wheel-like appearance of a crown of cilia which encircles the mouth. The current made by the motion of these cilia brings them food and, if the animals are free-swimming rather than attached to something stationary, carries them also from place to place. They closely resemble the larvae, or young stages, of most worms and many molluscs, and are thought to resemble roughly the ancestral form of these animals. They may be frozen or thoroughly dried and still become active again when conditions become favorable.

5—*Bryozoa* (moss animals) are a relatively unimportant group of some 1,750 species of marine and freshwater animals. *Plumatella* is a common freshwater representative. Fossil species of the *Bryozoa* are found in the rocks of the early Paleozoic era.

6—*Annelida* (segmented worms) include the earthworm. There are about 4,500 known species of annelid worms, divided into four classes which include the marine clam-worm and its relatives, the earthworms that burrow in the soil, and the leeches, which are chiefly limited to fresh water. All of these are separated from the other worms by having bodies divided into numerous segments. Typically there is a well-developed body cavity surrounding the digesting tract. The blood flows through well-developed blood vessels, a system not found in any of the simpler animals. Earthworms are of marked economic importance in opening up the subsoil by their burrowing.

Phylum **Mollusca** (soft body). In their embryology and early larval life the annelid worms and the *Mollusca* are very closely similar. This phylum contains the snails, clams, oysters, mussels, squids and the octopi, arranged in five classes and containing 60,000 known species living on land as well as in both fresh and salt water. Usually these animals have a soft body surrounded by a membranous mantle which secretes a shell. One of the most characteristic structures of this highly varied group is the presence of a flexible file-like device called the radula, which is used in obtaining food and in burrowing into wood and even into stone or the shells of other animals. This structure is absent in the great group of bi-valved molluscs, which includes the clams and mussels. Eyes are commonly developed which are remarkably like our own in general principle.

The adult structure varies greatly. Snails are fairly representative, except for their large coiled body. The mussels and their relatives, the clams and oysters, have lost almost all of their heads; the octopi and the squids have lost almost all of their shells, but have a well developed head from which spring eight or ten arms, bearing strong sucking discs, which are used to catch the animals they eat. Some mussels can move only about six feet a day, others are permanently attached to one spot; but squids swim rapidly enough to catch fish for their food. Many representatives of this phylum, like the clams and oysters, are used for food. The shells of others furnish buttons, mother-of-pearl and pearls. One group, the shipworm *Teredo*, is so destructive that in 1920-21, $20,000,000 had to be spent in replacing the wharf pilings of San Francisco Bay, which had been weakened by *Teredo* burrows.

Phylum **Arthropoda** (joint-footed). This phylum includes the crayfishes, crabs, lobsters, spiders, the "hundred-" and "thousand-legged" worms and the insects. These are divided into five classes of living animals. This assemblage includes also the trilobites, a commonly found fossil which somewhat resembles some modern crustaceans, or the young stages of the horseshoe crab, but which became extinct near the close of the Paleozoic era. The modern classes are all important enough for separate consideration.

Class 1—*Crustacea* (crust-like shell), including crayfish, lobsters, crabs and similar animals, are mainly marine and freshwater animals; 16,000 species are known. They breathe by means of gills and have two pairs of antennae or "feelers" on the head. Many of the *Crustacea* are used for food by man, and myriads more make food for aquatic animals, ranging from tiny minnows to whales.

Class 2—*Arachnida* (Arachne, the spinner) is a class containing the scorpions, ticks, mites and spiders. Almost all the known species live on land. They lack antennae, and they breathe by special devices known as lung-books and by piping the air directly to the tissues as the insects do. The young stages of the king crab, a marine member of this group, resemble the old fossil trilobites. Ticks and mites do great damage by sucking the blood of man and of domestic animals, and by carrying disease-producing parasites. Texas fever is scattered by one tick, and Rocky mountain spotted fever by another.

Class 3—*Peripatidea* (Peripatus) is a reduced class of about seventy-five species now found only in moist tropical countries. They are of great interest, because the group forms an almost perfect connecting link between the annelid worms and the insects.

Class 4—*Myriopoda* (many-footed) are frequently further subdivided into separate classes for the centipedes, or "hundred-legged" worms, and the diplopods, or "thousand-legged" worms. There are only about a thousand species, all living on land, and none of great importance.

Class 5—*Insecta* (cut into segments) are also called *Hexapoda* (six-legged). These are the insects; the study of them is the science of entomology. The insects may be described as six-legged arthropods which frequently have wings, which have one pair of antennae on their heads, and which breathe by means of trachea which carry the air directly to their tissues. The half million or more species are commonly divided into two subclasses and twenty-five orders.

Something of the importance of this one class of animals can be seen if we remember that the insects include three-fourths of all the known species of animals. The importance of insects to man is indicated by the fact that they annually destroy more than $2,000,000,000 worth of property in the United States alone. In other words, it takes the work of over a million men each year to offset the damage done by insects in this country. This property damage occurs in a region relatively unfavorable to insects. In tropical countries, insects and insect-borne diseases keep men from living in and using the most fertile districts. When this is carefully considered it becomes apparent that by ordinary objective standards the insects, rather than men, are the dominant or controlling animals on the earth today, in everything but the size of individuals. Only in rare tropical regions, as in the Panama Canal Zone, has man been able to hold them in check sufficiently to go about his work unharmed. In time this may become the age of man—the most highly developed mentally of the vertebrates—but at present man is only beginning to dispute the ascendancy of the highly specialized insects.

Important orders of insects are:

Orthoptera (straight-winged). Grasshoppers and locusts, which destroy grasses and growing plants.

Isoptera (similar-winged). Termites, called "white ants," tunnel in solid wood, which they destroy. They are particularly abundant in the tropics, but do damage as far north as Chicago.

Ephemerida (ephemeral). The May flies are an important natural food for fishes.

Odonata (toothed.) The dragon-flies destroy other insects.

Hemiptera (half-winged). True bugs. They suck plant juices.

Homoptera (wings alike). Aphids (plant lice) and scale insects suck plant juices. These are garden and orchard pests.

Coleoptera (sheathed wings). These are beetles. Some, like potato beetles, destroy vegetation. Others, like lady-bird beetles, destroy other insects.

Lepidoptera (sealed wings). The butterflies and moths. The gipsy moth, the brown-tail moth and others destroy vegetation. The larvae of some, like the silk-worm, produce silk.

Diptera (two wings). Flies and mosquitoes are in this group. They suck blood, carry disease germs and parasites and sometimes act as scavengers.

Hymenoptera (marriage wings). This includes the bees, wasps and ants. The name comes from the fact that the queen ants shed their wings after their mating flight. The Hymenoptera are especially remarkable for their high development of social life. In the ants may be recognized types of social organization corresponding to the hunting, the pastoral and the agricultural stages of human society. Ants join in common hunts for their prey; they keep and carefully attend aphids (plant-lice), and obtain honeydew from them; in the winter they carry the aphids into protected underground burrows to spend the cold weather, and in the spring transfer them to appropriate food plants. Certain species of ants, called the leaf-cutting ants, prepare suitable beds on which to grow a mushroom-like fungus which they use for food. When the queen ant starts a new colony, she carries some of this fungus with her for a new mushroom bed.

William M. Wheeler of Harvard has found that the social habit has arisen at least twenty-four times in as many different groups of insects that were at first of solitary habit. He says that social organization reaches its highest development among the wasps, bees and ants of the highly specialized *Hymenoptera*, and among the termites, *Isoptera*, which for insects have a relatively simple body structure.

Having followed the right hand branch of the animal kingdom as shown in the chart to its apex in the highly specialized insects, we must now return and take up the left hand line of development, which leads to the equally highly specialized groups of birds and mammals, with which we are more generally familiar.

Phylum **Echinodermata** (spiny skin). The starfishes, sea urchins and sea cucumbers are a marine group with about 4,000 living species divided into five living classes. There are two other classes that have become extinct and now are known only in fossil form. The echinoderms appear to belong to an entirely distinct series from that which we have been discussing. Their eggs are relatively smaller, and develop according to a less fixed pattern. Their larvae, which are free-swimming, are built upon an entirely different system from the free-swimming marine larvae of the worms and molluscs; and, as will be explained later, the mesoderm, the layer arising between the outer ectoderm and the inner endoderm of the developing larvae, arises in a different fashion, as does the body cavity. The echinoderms are built with a radial or wheel-like symmetry, like the coelenterates. Their nervous system is very poorly organized. They have developed a water vascular system which is characteristic of them. This water vascular system consists of a series of connected tubes or canals, containing slightly modified sea water. Projections from these canals extend outside of the animal as tube feet; among their many uses may be mentioned locomotion, collection of food, res-

piration and perception of light, contacts and chemicals.

Phylum **Brachiopoda** (arm-footed). The lamp-shells are members of a greatly reduced sea-living phylum, having only 120 living species, although about 2,500 fossil species are known. These fossil shells are common at various points in the Mississippi Valley where they stand as relics of the time when this whole central valley of North America was a vast shallow sea. The brachiopods have a larva like that of the worms, but the body cavity develops in the same way as in the young forms of the starfishes and sea urchins.

Phylum **Chordata** (having a notochord). This is the last of these great divisions of the animal kingdom to be considered. It is divided into 37,000 species, and includes the vertebrates. The chordates are characterized by the possession, either as adults or in some of their larval stages, of three body structures which all other animals lack. These are:

(1) A notochord, which is a rather stiff rod-like structure, lying between the digestive tract and the nervous system. It is replaced, in the vertebrate animals, by the vertebral column, or backbone.

(2) Gill slits, which are openings in the neck region from the digestive tract to the exterior, and are used for breathing by the lower chordates, fishes and tadpoles.

(3) A dorsal hollow nervous system. All the members of the entire worm and arthropod system have most of their nervous system to the side of or below the alimentary canal, with only the first nerve mass, or "brain," lying above or dorsal to it. In the chordates, on the other hand, the entire central nervous system lies dorsal to both the alimentary canal and the notochord. Unlike all other animals, the chordates possess a central nervous system that is hollow. We may note that the Echinoderms have three nervous systems, two on the lower or ventral side, and one in the upper or dorsal region.

The connection between the chordates and the echinoderms is made by the simplest of the three subphyla grouped in the chart as forming the lower chordates. This subphylum is known as *Hemichordata*, which means that the animals are half-chordates. The adults are marine, worm-like animals, (*Balanoglossus* is one) which burrow in the sandy mud of shallow ocean bays along with annelid worms. They have an outgrowth from the digestive tract which appears to be a start towards a notochord; therefore the name *Hemichordata*. They have distinct gill slits and possess both a dorsal and a ventral nervous system. Thus they appear to satisfy the chordate requirements fairly well, but they have a larva so much like that of the starfishes and sea urchins that for a long time it was thought to represent an unknown group of echinoderms, until finally it was proved to develop as an adult into this worm-like hemichordate.

The other subphyla, making up the lower chordate group, include the ascidians, or sea-squirts, and the lancet-like animal called *Amphioxus*. All these lower chordates are marine.

Subphylum *Vertebrata* (having vertebrae or backbones). Fishes, frogs, reptiles, birds and mammals make a group of only about 36,000 known species, as compared with the half million known species of insects; but the average individual is much larger in size. Representatives of this group may be found in fresh or salt water, or on land.

The least specialized vertebrate animals are the fishes, *Pisces*; and the most primitive of these lack both jaws and paired fins, which were apparently the forerunners of the legs of higher vertebrates. The brook lamprey of our streams is an example of such primitive fish. The lampreys belong to a group called *Cyclostoma*, which means "circle-mouths," and are usually regarded as belonging to a distinct class of vertebrates.

The true fishes had developed jaws and paired fins back in the Devonian period of the Paleozoic era, in what is now known as the "Age of Fishes." The early fishes had skeletons of cartilage, as the modern group of sharks have today, but they early developed bony structures, both as an internal skeleton and also as an external covering.

It is interesting to note that if we were to take only one animal to be an example of the whole animal kingdom, a median representative of the whole lot, we should have to choose an annelid worm, perhaps an earthworm; and if we were to choose similarly a median representative of the chordate phylum we should have to take a shark-like fish. This is a low type of vertebrate, but it is about half way up the chordate scale and thus is a median representative.

Some of the fishes developed lungs, but apparently the amphibians, Class *Amphibia*, (double lives) which were the first land vertebrates, are more closely related to the ancestors of the lung-fishes than to the lung-fishes themselves. Amphibians began to live on land about the time coal beds were being laid down, in the carboniferous period of the Paleozoic era, just before the first insect fossils are found.

The amphibia have not been remarkably successful as a class. Modern frogs and toads are common, but relatively unimportant, animals. The amphibians gave rise to the great class of reptiles; this is shown in the fossil beds of the Permian rocks of Texas, where very close gradations are found between the two types, so that it is hard to distinguish them. The reptiles introduced among vertebrates eggs that have power to develop out of water. The Mesozoic era became the age of reptiles. They were at that time the most successful vertebrates of water, air or land. The majority of these old reptiles, of which the dinosaurs are the most widely known, have been extinct for a long time, and the group is now represented by a relatively sparse collection of crocodiles, turtles, lizards and snakes. Not all of these ancient beasts were large, but some reached the gigantic length of eighty feet, much of which was neck and tail, while others probably weighed as much as fifty tons. They left two distinct types of successors: the birds, Class *Aves*, and the mammals, Class *Mammalia*.

These two classes rose independently of each other, and independently arrived at a warm-blooded condition, which makes surrounding temperatures less important to them than to any other animals. Fossil records connect the birds, which may be accurately called "feathered vertebrates," with the reptiles. Their close connections to the reptiles is also shown in their method of development in embryo, and in many details of adult body structures.

The oldest bird known is the fossil *Archeopteryx*, which was found in the Jurassic rocks of Germany. It was about the size of a crow. It had toothed jaws, as do modern bird embryos, though modern adult birds never have teeth. *Archeopteryx* also had a long, dinosaur-like tail, with fringing feathers. The "wings" were also feathered, but otherwise they were like dinosaur "arms" with fingers that ended in claws. Bird feathers are believed to have been developed from reptilian scales. So close is the relationship between birds and reptiles that birds are often spoken of as glorified warm-blooded reptiles, close relatives of the old dinosaurs.

Modern birds are divided into two main groups, the running birds, *Ratitae*, which are represented by the ostrich and the flying birds, *Carinatae*, which include all our common birds. The structure of flying birds can best be understood when we think of them as living flying-machines. The essentials of a successful heavier-than-air, all-the-year round flying machine are: (1) supporting planes, (2) great power adequate for long flights, (3) light weight, (4) rigidity, (5) stability, (6) steering and balancing devices and (7) protection from cold.

These essential characteristics the bird possesses as follows: (1) planes—wings and tail with their strong flight feathers; (2) power—high body temperature of 104°F. as compared with 98°F. for many mammals, allowing more rapid digestion and greater activity of muscles; powerful breast muscles well supplied with blood by a relatively large heart, and with oxygen by a system of breathing which is more efficient than that of mammals; (3) light weight—made possible by hollow bones, since hollow structures are stronger, weight for weight, than are solids, and by extensive air sacs distributed through the body, which not only aid breathing but give added boyancy; (4) rigidity—obtained by the fusion of the bones of the back; (5) stability in flight—obtained by the location of all the heavy muscles below the wings, so that even the muscles that lift the wings are located below them and are attached to the wing-bones by a long cord-like tendon which operates through a ring of bone, acting on the principle of a pulley; (6) steering—accomplished by the use of tail and wings; (7) balancing—by means of a flexible neck and the proper adjustment between load and point of support in the air, and (8) protection from cold — by feathers with their enclosed air spaces.

Mammals (Class *Mammalia*) solved the problem of the conservation of body heat by the development of hair. They can be adequately defined as "hairy vertebrates," just as birds can be distinguished as feathered vertebrates. Mammals are further characterized by their possession of mammary glands (from which the name, mammals, is derived) by which they suckle their young. They, too, arose from the reptiles, but from small, lightly built, running types of reptiles. They appear to have arisen in the geological period just before the birds, and near the beginning of the great age of reptiles.

Three subclasses of mammals are recog-

nized. The first is the *Prototheria* (primitive mammals) which retain the reptilian habit of egg-laying, along with certain reptile-like structures. The duckbill (*Platypus*) of Australia and Tasmania and the spiny ant-eater of the same region are examples. Both have primitive milk-glands; the young, after hatching from the egg, lick off the milk as it drips from the hairs covering the glands.

Marsupalia (pouched animals) are represented by the American opossum and by kangaroos and many related forms of the Australian region. The young are born in a very immature condition. The young of a large kangaroo that would reach to man's shoulder is, at birth, about the size of a man's little finger. These tiny animals travel along the abdomen of their mother to a pouch where the mammary glands open; within this pouch they attach themselves, and there complete their development. In Australia, where they have had no competition from higher mammals, marsupials have become adapted to most of the different environments where mammals can live. They burrow and climb trees, as well as run over the earth's surface. Both carnivorous (flesh-eating) and herbivorous (plant-eating) forms occur.

The third mammalian subclass is that of the *Eutheria*. The name means "true animals" and is given because these are the common hairy animals with which we are most familiar. These animals are characterized by a placenta, which is the organ of attachment of the developing embryo to its mother. Here the young animal develops as a parasite within the mother, and birth takes place at a relatively late stage in development. In many mammals of this class as, for example, the deer, the young can run about, following their mother, within a few hours after birth. Other vertebrates, as well as some invertebrates, bring forth their young alive, but only among the *Eutheria* is there a true placental attachment between the mother and the young. Usually, among other animals, the eggs are merely kept within the mother's body and hatched out there, instead of the ordinary laying and incubating of the eggs outside the body.

There are four main types of these highest mammals. The first is that of the clawed mammals, which are the least specialized of all. They include the shrews, moles, hedgehogs, the bats and the carnivores. The last is a large flesh-eating order with two suborders: the land carnivores, which include the cats, dogs, hyenas and bears; and the marine carnivores, which are the seals, the sea lions and the walruses. The great order of rodents, or gnawing mammals, including rats, mice, rabbits and squirrels; the so-called *Edentates*, or toothless sloths and armadillos (though these actually do have teeth), and the ant-eaters, also belong to the division of clawed animals, making seven orders in all.

The second type, the next most generalized group of mammals, includes those with flattened horny growths, called nails, at the end of their fingers and toes. This group contains only one order, the *Primates*, which include lemurs, monkeys, apes and man. In mental power, man far outdistances any other animal; but in structure and even in many aspects of behavior, he is similar to the great apes. Some generalized features of this group are: the possession of five fingers or toes on each limb, a clavicle or collar bone, and relatively normal proportions of the bones of the arm and leg as contrasted with the great specialization to be found in the next group.

The third type, the hoofed mammals, includes the even-toed animals, like swine, hippopotamuses, camels, deer, elk, giraffes, cattle, buffaloes, antelopes, gazelles, sheep and goats; and the odd-toed animals, such as horses, zebras, tapirs and rhinoceroses. The elephants and coneys are also placed here; and manatees, or sea cows, are aquatic forms related to this general assemblage. Here the greater specialization is shown by the great elongation of the finger bones. The knee of the horse is the equivalent of the human wrist or ankle joint, while the joint corresponding to the human elbow or knee occurs up next the body. There is a loss of one or more of the fingers or toes, culminating in the horses that walk on the tips of their middle toes, having lost two toes of each foot completely, and almost all of two more. Many of this group have lost the collar bone entirely, and have more highly specialized teeth than the preceding groups.

The fourth type, that of the most highly specialized mammals, includes the whales and dolphins. This estimate of the cetaceans specialization is supported by the following facts: (1) They have lost almost all hair, which is a most distinctive mammalian character. Some have no teeth as adults; and the hind limbs and almost the entire pelvic girdle are lacking. (2) The skeleton of the fore limbs (flippers) is specialized by the addition of several digits or "fingers." (3) They have reached a bulk unrivaled in animal history, far surpassing the great reptiles of the past. A whale accurately measured on the Gulf coast of Texas was found to be sixty-three and one-half feet long with a circumference in front of the flippers of thirty-seven feet and a height of twelve feet. This great diameter was maintained from the end of the snout to within about fifteen feet of the tail. It was estimated to weigh well over eighty tons. (4) The stomach is the most complex among mammals, more complex even than that of the camel or cow. (5) The skull is also the most specialized to be found among mammals.

EMBRYOLOGY

There are two main types of reproduction among animals, the sexual and the non-sexual. Sexual production involves the union of two germ cells or their equivalents, which usually arise from two separate animals. Non-sexual reproduction is the simpler process. In the simplest form of non-sexual reproduction, as in the protozoans, it consists of a nearly even division of the entire animal body, which here consists of one cell, into two daughter cells, each of which then grows to adult size.

Variations of this process occur, such as budding, which resembles budding in plants, and in which an offshoot grows from the main animal, finally breaking off from the parent to form a separate individual. When these budded individuals do not separate entirely from the original animal, colonies of connected individuals occur, as in the hydroids. Some animals reproduce non-sexually by forming spores or gemmules, which are small bits of protoplasm surrounded by protective material, and thereby are enabled to withstand severe conditions, such as extreme cold, heat or drought. Some protozoans and some sponges reproduce in this manner.

Many of the simpler animals, including even tadpoles and lizards, can regrow lost parts of their bodies. Others can regenerate a whole animal from a fragment. Sponges, hydroids, flatworms and echinoderms have this power to a marked degree. Breaking off of parts of the body often occurs in nature, either because of accident or as a result of the activity of the animal itself, and these pieces may develop new whole animals. The loss of such power of regeneration is one of the penalties of specialization.

Sexual reproduction is the usual method of reproduction in animals. In the simplest form the sperm and the eggs are shed into the water as, for example, in fishes. A sperm fuses with an egg and thus starts the development of a new animal. The fertilized egg consists of one cell, whether this be microscopic, as it usually is, or the entire large yolk of a hen's egg.

Shortly after fertilization the egg divides into two cells, then successively into four cells, eight, sixteen, thirty-two and so on, forming gradually and typically into the shape of a hollow ball, whose surface is made up of a single layer of cells. This ball of cells is called a *blastula*. Among water-living animals it is supplied with cilia and swims actively through the water, much as *Volvox*, an adult colonial fresh-water protozoan, does, except that the latter has flagella rather than cilia. All sexually produced animals, except protozoans and sponges, go through a blastula stage in their development, although in animals like chickens, the blastula is represented by a flat sheet of cells rather than by a hollow ball.

After the blastula is fully formed the cells in the different parts begin to behave differently. At the so-called *animal pole* the cells divide rapidly, and are relatively small. At the opposite or *vegetative pole* they are slower to divide, and contain more yolk or food material. Eventually the more rapidly growing cells tend to enclose the others, forming a structure like a hollow rubber ball, one end of which has been pushed in until it forms a sort of lining for the other half. The inside cells are called the *endoderm;* the enclosed cavity, which opens to the outside at the posterior end, is called the *primitive gut*, and develops into the alimentary canal; the outside cells are called the *ectoderm*. These are the first two layers of the developing embryo. This level of development is called the *gastrula* stage, and all animals that reproduce sexually, protozoans and sponges excepted, pass through a recognizable gastrula stage. Some animals never develop farther. The whole group of hydroids, jelly fishes and sea anemones are built upon this plan.

In the higher animals, the ectoderm gives rise to the skin and the lining of the ends of the alimentary canal, as well as to the nervous system and the sensory part of the sense organs. The endoderm forms the lining of the alimentary canal and the lining of the organs that arise from it—the lungs, liver and pancreas, for example.

Between the ectoderm and the endoderm, after the gastrula stage, a new germ layer develops. It is called the *mesoderm*, and gives rise to the rest of the body, including such parts as the bones, muscles, blood, connective tissues, cartilage and reproductive organs.

The mesoderm arises differently in the two main branches of the animal kingdom shown in the chart "Animal Relationships" (p. 957). In the right hand branch, among the worms and molluscs, it grows from two cells which lie at the connecting point between the ectoderm and endoderm, and are called *pole cells*. In the echinoderms and lower chordates, it arises as an outpocketing of the primitive gut wall, and, therefore, from the endoderm. The hollow ball of mesoderm thus formed develops into the body cavity of the adult echinoderms and *Amphioxus;* while on the other branch of the animal kingdom, in the worms, the body cavity develops as a result of a splitting of the developing mesoderm bands.

The development of the definite organs of the body of any given animal should be studied from this point in detail, for all differ. Long courses in colleges and universities are given to describe these different developments. It is interesting and valuable to trace here the further history of a few organs in the common frog.

In the frog, the first opening of the primitive gut of the gastrula does not form the mouth. This organ arises, rather, from an ingrowth of the ectoderm and forms the mouth opening by fusing with the gut ectoderm. Gill pouches grow out from the endoderm in the neck region and form contacts with the ectoderm. Openings break through, forming gill slits. An outgrowth at the base of the second gill slit becomes the thyroid, an important gland of internal secretion. The first gill pouch is transformed into the middle ear and the tube which connects it with the back of the mouth, even in adult life. The sensitive part of the ear, the inner ear, develops as a pouch of ectoderm which cuts loose from the surface and comes to lie deeper than the middle ear.

The lungs develop as an outgrowth from the lower side of the alimentary canal behind the gill slits. Farther back the canal enlarges to form the stomach, and behind this arise outgrowths which will form the liver and the pancreas.

Above the developing alimentary canal, a cylindrical rod of cells is pinched off which forms the notochord, or forerunner of the backbone. The bones themselves, however, come from the mesoderm. Above this, on the dorsal or upper side of the growing animal, a parallel pair of ridges appeared very early. These grew until they finally formed a hollow tube, broad at the front end, from which the brain develops, and narrower behind, where the spinal cord arises. The eye begins as an outgrowth from the side of the brain. This first outgrowth folds on itself to form the retina, or sensitive part of the eye. The lens and outer surface of the eye develops from the surface ectoderm. The other structures of the eye are formed from the surrounding mesoderm.

The olfactory, or smelling organs, arise as a patch of thickened surface ectoderm. This lies just above the future mouth. It deepens to form a pocket which never closes but remains open as a nostril. It gradually deepens and finally opens into the back part of the mouth. The ear arises similarly but farther from the front end of the animal. Unlike the nostrils, the auditory sac becomes entirely closed off from direct connection with the surface or with other internal cavities.

The heart develops from a pair of blood tubes which arise in the mesoderm and which fuse to form a simple tubular heart, such as the fishes possess. Later this develops the more complex structures characteristic of the frog's heart.

There are some animals widely scattered through the animal kingdom that have eggs which develop without fertilization. This is called *parthenogenesis*. Parthenogenesis occurs in rotifers, plant lice, bees and other animals. Some animals whose eggs normally require fertilization by a sperm can be started in their development by special treatment, such as shaking the egg, treating it with chemicals or by mechanical injury. Echinoderm eggs are particularly easy to start toward artificial development. Even the egg of a frog can be artificially stimulated to develop without the presence of a sperm, and an adult frog can be reared from an egg whose development was started by pricking it with a hot needle.

HISTOLOGY

Histology is the study of the structure of animal tissues seen under the microscope. A tissue may be defined as a group of cells, or of cells plus their products, grouped together to form a definite structure and to perform common functions. The same sorts of tissues are widespread in the animal kingdom. We can recognize the following kinds:

Epithelial Tissues. Epithelial cells are usually flattened, but may be of various shapes. They are united to form a membrane which protects exposed surfaces just as the skin covers the surface of the body, or the epithelium lines the mouth. It also makes up the lining membranes of glands and of the body cavity. Epithelial tissue, then, is a layer of closely compacted cells covering an internal or external surface of the body, one surface being free and the other resting on underlying tissue. It serves to protect the more sensitive tissues, and allows the passage of waste or food substances to or from the blood. It also serves as an organ of secretion or excretion. The sensitive parts of sense organs are the epithelial layers. Epithelial cells of the reproductive organs may retain the power of individual growth and thus become germ cells. Outgrowths from epithelial cells become hair, nails, hoofs, cilia, flagella, and so on. In structure the epithelium may be thick or thin; and it may arise from either ectoderm, endoderm or mesoderm.

Connective Tissue. In the different sorts of connective tissue the intercellular substance determines the character of the tissue. The cells are not conspicuous. All connective tissues arise from the mesoderm. The following kinds are recognized:

Fibrous. Fibrous connective tissue has fibers so well developed that the cells are hard to discover among them. This tissue is used as sheathes over muscles or bones, and as tendons to connect muscles with bones and as ligaments to fasten bones together. It also serves as mesenteries in supporting internal organs, and forms the main part of the walls of blood vessels. The fibers are not cells, but are the product of cells. There are two sorts of fibers: those of the white inelastic and the yellow elastic connective tissue.

Adipose or Fatty Tissue. This is composed of connective tissue cells that have the power to store fat. The fat is usually laid down within the cells until the cell protoplasm is crowded off to one side. Fat cells, if many are present, are gathered into groups or clusters, which may form layers. Fat is a chemical compound of glycerine and fatty acids, and is used within the animal body as a reserve supply of food, for protection of underlying organs, and to conserve body heat. In starvation, the fatty cells are the first to become shrunken.

Cartilage. This is formed by the cells which surround themselves with a clear heavy substance in which they become embedded. The cells occupy spaces called *lacunae*. Cartilage may be either elastic or inelastic. It covers the joints of bones, and fills in places as a substitute for bone. Some animals have the entire skeleton of cartilage; and embryos of higher vertebrates usually pass through a cartilaginous stage. Cartilage frequently hardens with age.

Bone. Bone may develop either from a cartilage or from a fibrous connective tissue basis. As in cartilage, the bone cells are much separated by intercellular bony material, the main part of which is phosphate of lime. Each cell lies in a space, or lacuna, which communicates with the other lacunae by means of tiny canals running through the bony substance. These, in turn, connect with a large canal which contains blood vessels that carry food and oxygen to the bone-locked cells. The bone cells are arranged in concentric circles around the large canals. The surface of a living bone is covered by a layer of fibrous connective tissue. Bones serve for support, as levers, and for protection. Bone is most common in vertebrates, but is also present in the king crab, which is a sea-animal related to the spiders.

Muscles or Contractile Tissues. There are two types of muscle cells, the smooth and the striated, or striped, cells. Each smooth muscle cell has a nucleus. The *cytoplasm*, as the protoplasm around the nucleus is called, contains longitudinal fibrils. In higher animals these smooth muscle cells occur in organs where rapid contraction is unnecessary, such as the digestive tract, the gall bladder, the walls of arteries and veins, and in some glands. They are not subject to direct mental control, and are usually called the involuntary muscles on that account. They arise from primitive mesoderm cells or from embryonic connective tissue cells.

Striated muscle differs from smooth muscle in having the fibrils striated or striped. Ordinarily they have long, straight, unbranched fibers, although the fibers of vertebrate heart muscle are branched. Muscle fibers arose from cells in the embryo, each of which had a single nucleus; but after a time the division of the nucleus was not followed by a division of the cell, so the cells became very large and possessed many nuclei. The contractile fibrils

are not present in young cells, but develop as secretions within the cell. There is good reason for thinking that they are non-living cell products which are made and kept working by the surrounding living protoplasm. The fibrils are merely contracting machines.

Exactly how muscles work is not known. The best theory is that, on stimulation, the material in the dark stripes of the fibrils absorbs material from the light stripes. Since each dark stripe was originally long and narrow, it tends to become spherical with the material taken in. This thickening of the dark stripes causes the thickening of the muscle which accompanies contraction. By absorption from the light stripes, the dark stripes are brought close together. This constitutes contraction, and accounts for the shortening.

According to this theory, stimulation to contraction results first in stimulation of the protoplasm, and only indirectly acts on the fibrils. During contraction the protoplasm produces a lactic acid called here sarcolactic acid. Oxygen is not used by the fibrils in the contraction process, but is used by the protoplasm to restore the fibrils to a condition of high potential energy. The sarcolactic acid is consumed during this process, and carbon dioxide is given off.

In addition to contracting, striped muscles give contour to the body and protect underlying organs.

Blood, the Circulating Tissue. The blood is a liquid tissue occupying a set of tubes in the higher animals, but circulating in spaces between the other tissues in less specialized forms. The tubes are not a part of the blood tissue, although their lining membrane must be so considered, because one cannot be changed without affecting the other very directly. Blood is composed of two main parts, the liquid plasma and the solid corpuscles. Of these the plasma is commonly regarded as the intercellular, lifeless part of the blood corresponding to the lifeless part of bone. It acts as passive carrier of food and waste products. The corpuscles in the vertebrates are the red and the white. The red blood corpuscles of fishes, amphibians, reptiles and birds have nuclei like other cells. Those of mammals do also in embryonic stages, and pass successively through stages, resembling those found in fishes, amphibians and reptiles, and then entirely lose their nuclei, becoming degenerate cells.

The red blood corpuscles have an unusually large surface for their bulk. Thus a man weighing 150 pounds would have about four quarts of blood, which would contain approximately 16,000,000,000,000 red blood corpuscles with a surface of almost 17,000 square feet. This vast surface expanse is related to the oxygen carrying power of the blood.

The red blood corpuscles of vertebrates contain a pigment called *haemoglobin*, which is related chemically to the green chlorophyll of plants. This is the material that combines with oxygen at the gills or lungs and conveys it to the tissues. It also occurs in other animals, as in certain molluscs and in the earthworm. In these cases, it is found in the blood plasma rather than in the corpuscles. Haemoglobin contains iron. Many invertebrates have a compound called *haemocyanin* in their blood, in place of haemoglobin. This contains copper rather than iron, and is far less efficient as an oxygen carrier than is haemoglobin. It turns distinctly blue when well aerated, whereas haemoglobin becomes scarlet under this condition.

The white blood corpuscles occur widely in the animal kingdom. They are amoeba-like cells that have the power to leave the regular blood tubes and wander freely through the tissues where they destroy old tissues or bacterial invaders. They thus act to check disease invasions and to destroy the old structures including those of larvae at the time the latter metamorphose into adults.

Nervous Tissue, the master tissue, is composed of cells which possess from one to many outgrowths, some of which may be several feet in length in a large animal. Those of the cells in the lower part of the spinal cord reach to the feet. The principal properties of these cells are their irritability and conductibility. In the hydroids, the simplest animals to have separate nerve cells, these are scattered about singly, connected with each other by a network of nerve fibers. Even here they tend to be more numerous about the mouth region. In most other animals they are collected into smaller or larger masses, which are usually called *ganglia*. Great collections of nerve cells occur in the gray matter of the brain and of the spinal cord of the vertebrates; but ganglia are found even in this group, lying outside the central nervous system.

The nerve fibers of the invertebrates are naked, while those of the vertebrates are surrounded with an insulating sheath called a *medulla*. In the former the different nerve cells may be directly joined with each other. In the latter, however, the nerve processes end in a brush-like arrangement which interlocks with another similar end-brush of another nerve cell without coming into direct contact with it. These individual nerve cells, with all their connecting outgrowths, are called *neurons*. The interlocking arrangement between the different neurons is called a *synapse*. The brush-like synapse allows a nerve impulse to jump from one neurone to another.

The simplest nerve mechanism in the higher animals consists of a reflex arc. If we examine a sense organ in the skin, for example, we would find a sensory brush of fibrils which connects with a main nerve process, called a *sensory process*. This, then, connects with a nerve cell in the dorsal part of the spinal cord. By a synapse or a series of synapses, this sensory cell is in connection with a motor cell in the ventral part of the cord which, in turn, is connected by one of its processes with a muscle or gland. If the sensory element (receptor) is stimulated, an impulse is sent along to the nerve cells in the spinal cord, which act as adjustors and which, in turn, relay a stimulus to some appropriate effector. If the sensation is of sufficient importance—which may mean merely if it is of sufficient strength—it may be sent along another system of neurones to the brain, and may eventually come to the conscious attention of the individual.

In the hydroids, the nervous system arises both in the ectoderm and the endoderm; but in the higher animals it is restricted to the ectoderm in its origin.

PHYSIOLOGY

Physiology deals with the functions of plants and animals, either as a whole, in general physiology, or of their different parts, in special physiology. Physiologists try to find what the living processes are, and to determine their exact causes. Physiology is sometimes divided into plant physiology and animal physiology, but there is no real difference between the general physiology of the two. Plant physiology is much concerned with the manufacture of sugar by the green plants under the influence of light, commonly called *photosynthesis;* and with the loss of water from exposed plant surfaces, both of which are subjects of indirect or minor importance to animals. On the other hand, general physiology of animals must consider the problem of locomotion, and problems centering about the well developed organ systems, such as the nervous system. These are the chief differences, but the similarities are many.

The study of physiology has brought out the importance of certain laws of physics and chemistry as applied also to living matter, and has led many persons to think that living and non-living processes are probably parts of the same general system.

From these laws we may select the following: (1) The law of continuity, which states that there is no break in nature or in natural processes. (2) The law of the conservation of energy. Careful tests on the total energy intake and outgo in men placed in specially constructed rooms, which allow the measurement of the energy value of all food consumed and all heat, work and wastes produced, have shown that even in man the energy outgo can be no greater than the energy intake. Living things can transform, but cannot manufacture, energy. (3) The law of the conservation of matter, which states that matter cannot be created or destroyed, by living or non-living substances, no matter how its form is changed. (4) Laws dealing with chemical proportions worked out for inorganic chemical compounds hold also for chemical compounds found in living things. (5) The laws of thermodynamics. The first of these laws states that in any change involving heat and work, a definite amount of heat is expended or goes out of existence for every unit of mechanical work done. The opposite also holds. The second law of thermodynamics states that it is impossible for a self-acting machine, working independently of any assisting set of forces, to convey heat from one body to another which is already at a higher temperature. (6) The common gas laws of physics apply particularly to breathing, including the laws growing out of the process of diffusion.

It is generally well known that gas, enclosed in a vessel, distributes itself equally through the container regardless of other gases present. When two containers holding different gases as, for example, oxygen and hydrogen, are connected with each other, each gas diffuses into the other container, moving from the region of highest to that of lowest concentration of each gas. Diffusion applies also to the mutual distribution of gases and liquids, as air into water; liquids with other liquids; gases and solids; liquids and solids and the slow diffusion of one solid into

another. At least a part of the process of dissolving or going into solution represents the process of the diffusion of a solid into a liquid, as of sugar into water.

In physiology the diffusion of gases or liquids through membranes is of the greatest importance. A membrane in this sense means any thin, soft, pliable sheet of animal or vegetable tissue, which may be a cell wall, or a tissue composed of many cells, or even a membrane inside a given cell. Epithelial tissues are specially concerned with this sort of diffusion. As the amount of water present in such a membrane becomes less, diffusion takes place less rapidly and the membrane is said to be less permeable. If the permeability is lessened to a point where the solvent, usually water, and not the dissolved salt or other dissolved substance can pass through, the membrane is said to be truly semi-permeable. Most membranes are only partly semi-permeable; some, the outer layer of the skin, for example, are nearly or quite impermeable to watery solutions.

Diffusion through a membrane is called *osmosis*. Even the physics and chemistry of this process are not clearly understood; but in general we can say that here, as elsewhere, a substance tends to move from the region of greater to that of lesser concentration, even if in so doing it must pass through one or more membranes.

Semi-permeable membranes that allow water to pass, but which hold back materials like sugar or salt dissolved in the water, allow what is called *osmotic pressure* to develop. Osmotic pressure may be defined as the amount of pressure necessary to keep the solvent (water in the above case) from diffusing through a semi-permeable membrane. Among the physiological effects of osmotic pressure, we may mention the fact that cells are usually under an internal pressure which causes their contents to flow out if the limiting membrane is broken. This pressure is called *turgor*, and makes the outstanding difference between an active and a dried plant or animal. Osmotic pressure is easily shown in the laboratory by putting a membrane, as from the bladder of a hog, over the end of a tube which contains sugar or salt, and then immersing the covered end in water. The water will rise within the tube much above the level outside.

Osmosis is also concerned with such necessary processes as the movement of food or waste material or oxygen into and out of the blood. Some physiological processes, such as secretion and excretion, may be carried on in direct opposition to the laws of osmosis as now understood. In other words, it appears that in such processes the living cells are able to exert some sort of force which overcomes the normal working of osmosis. The nature of this force is not yet understood. The fact that it exists is one of the reasons that keeps us from being certain that physiological processes can be fully explained in terms of physics and chemistry.

Physiology of Systems. The physiology of different organ systems has been, in part, suggested in dealing with tissues. Additional facts will be sketched here. This subject is discussed at length in any text on human physiology.

The Transport System. This system consists of the heart, lymph and blood, blood and lymph vessels or their equivalent on the one hand, and the respiratory passages on the other. The general function of the blood has been suggested in the section on histology. The uses of the blood as a transport system are: (1) to carry food and oxygen to every part of the body; (2) to carry away waste products; (3) to carry internal secretions which serve as chemical regulators of the body; (4) to protect the body from the invasion of protozoans and bacteria and (5) to furnish the tissues a balanced salt solution of the composition and strength most favorable for their best work.

The degree of development of the blood transport system depends on: (1) The size of the animal; some small crustaceans lack hearts, although their larger relatives, such as crayfish, have them and many blood vessels as well. In the small animals, the blood moves about as a result of the movement of the entire animal. (2) The relative degree of specialization of tissues. Nervous tissue requires a better blood supply than does fatty or bony tissue. (3) The general activity of the animal, though there are exceptions, as seen below. (4) The method of respiration.

It is one of the inconsistencies of animal physiology that those animals capable of the greatest activity in proportion to their size—the insects—should have a poorly developed circulatory system. The reason is that here air tubes, or trachea, carry air directly to the tissues that use it, so that the blood need carry only food and remove wastes.

The Digestive System. The work of the digestive system is to dissolve food so that it will pass through the semi-permeable membrane of the wall of the digestive tract. This is accomplished rapidly and at ordinary temperatures, without harming the delicate lining walls of the digestive tract. In the chemical laboratory great heat and strong chemicals are required to do such work at a similar speed. This is accomplished in animals and plants by the aid of digestive ferments called *enzymes*.

There are three main classes of animal food: (1) the proteins, of which lean meat is chiefly composed; (2) the fats, and (3) the carbohydrates, such as starch and sugar.

The food of the majority of lower animals consists largely of protein, and their digestive systems contain mainly protein-splitting enzymes. In more complex animals, when fats and carbohydrates form important foods, there is an increasing number of fat- and carbohydrate-splitting enzymes.

Pepsin is a protein-splitting enzyme found in the stomach of higher animals. It works in an acid medium to split insoluble protein with a molecular weight of about 5,000, into peptones with a molecular weight of from 250 to 400. Peptones are soluble and can pass through the walls of the stomach, into the blood. But it appears that only about half of the protein present undergoes even this splitting.

Trypsin continues the splitting of protein. It acts in an alkaline medium, breaking the protein molecules into their constituent building stones called *animoacids*, with a molecular weight as low as seventy-five. These can pass through the intestine walls. Trypsin can attack complex proteins. It is found in the intestines of the higher animals and is widely distributed among animals, occurring in all the important phyla. It is supplemented by *erepsin*, which acts upon simpler proteins. Erepsin is mainly limited to the vertebrates.

Lipase is the enzyme that attacks fats, converting them into fatty acids and glycerine. If there is a great deal of fatty acid and glycerine, and only a small amount of fat present, it acts in the reverse fashion—to build up fats—and thus serves to store fat in the body as well as to digest it in the alimentary canal. Lipase has not been found in *Protozoa*, but does occur in the other important phyla.

Carbohydrates are acted upon by a large number of enzymes, none of which has been found with certainty in the protozoans. Thus *cellulase* changes the pithy part of plants, cellulose, into a sugar called *maltose*. *Amylase* changes starch into maltose. *Invertase* splits cane sugar into the simpler sugars, *dextrose* and *levulose*. *Lactase* splits milk sugar into dextrose and *galactose*. In man, starch-splitting enzymes are found in the saliva of the mouth and in the intestines.

The Integrating System is composed of two parts, the glands of internal secretion and the nervous system.

The Glands of Internal Secretion. These are also called the *endocrine* organs. Each secretes some substance of distinct value to the animal directly into the blood stream, rather than into a well-recognized duct, as for example, the salivary glands do. We do not know how many structures in the body may be organs of internal secretion.

Among those known to have such a function are: the pineal body and the pituitary body of the brain; the thyroid and parathyroids of the neck, and the thymus of the upper chest; the pancreas of the digestive system and, possibly, the inner wall of the stomach, the lining of the small intestine and of the vermiform appendix; the ovary, placenta and testes of the reproductive system; and the adrenal glands near the kidneys. Muscles also give off such regulatory substances. The materials given off by these glands of internal secretion are called *hormones*, which are chemical regulators of growth and activity of the body.

The *pineal gland* is a small extension of the roof of the brain, just back of the cerebral hemispheres. It is most active in young animals, and its secretion acts somewhat like that of the thymus, which is discussed below. No definite hormone has been isolated from it.

The *pituitary gland* is located at the base of the brain, back of the nose. It is about the size of a pea. Two kinds of hormones from this gland are known. One, together with thyroid secretion, influences growth and development. Too little of these secretions causes dwarfs; too much produces giants. It also markedly influences brain activity. The other hormone from the pituitary body helps control the tension of the blood vessels and affects emotional control.

The *thyroid gland* of the neck puts a definite hormone, called *thyroxin*, into the blood. This substance controls the rate of metabolism within the body; affects the development of organs; neutralizes bacterial poisons; affects the condition of the skin and other

body membranes, as well as the general tone of sense organs and nerves.

The *parathyroid glands* are closely associated with the thyroid. Their hormone has not been isolated, but their removal is usually fatal within a few days and is accompanied with nervous disturbances. The gland appears to control the use of calcium by the body, which in turn is known to affect the irritability of the different cells.

The *thymus gland* of the upper chest region is active in young animals. Its secretion, together with that of the pineal body, acts as a check upon the other glands of internal secretion. During its period of activity the individual remains sexually immature and keeps its juvenile characteristics. Its hormone has not been isolated.

The *pancreas* is an important gland in the digestive system, producing protein-, fat- and carbohydrate-splitting enzymes, which are delivered by the pancreatic duct into the small intestine near the stomach. In addition, it pours into the blood stream an internal secretion called *insulin*, which serves, in coöperation with adrenalin, (see below) to control the ability of the body to use sugar. Too little insulin in the body leads to the disturbance known as diabetes.

The *adrenal glands* lie near the kidneys. Their secretion, *adrenalin*, is well known and can be made in the chemical laboratory. Adrenalin acts to regulate blood pressure and the distribution of the blood to different parts of the body. A slight increase in adrenalin causes the blood to flow to muscles and brain, and away from the digestive organs. The reverse occurs when the supply is decreased.

The action of these hormones, and of the nervous system, the activities of which were suggested above, tends to bring the tissues, organs and systems of any animal into a unified whole, which behaves as an individual, rather than as a collection of independent parts.

The whole story of the relationship between the work of these glands and the structure and behavior of the vertebrates, including man, is an interesting chapter in physiology. But it is so complex that it is best to seek a further explanation of it in books devoted to the effects produced by these glands of internal secretion.

ANIMAL BEHAVIOR

Study of the activities of animals is called *animal behavior*. Four grades of behavior are recognized: (1) the simple reflexes, such as winking or swallowing. (2) Reflex actions of the entire animal, commonly called *tropisms*, which may be direct and machine-like, as when a moth orients and moves directly toward a light; or which may be more at random, as when an earthworm moves about uneasily until it finds, apparently by accident, the most comfortable soil in which to come to rest. (3) When tropisms are complex they are called *instincts*. All of these are the expression of inherited, unlearned behavior. (4) Finally there is the conditioned or learned behavior, which has been modified by the experience of the individual animal. This is sometimes called *intelligent* behavior and is best developed in man, while the tropisms and instincts find their highest development among the insects.

ECOLOGY

Ecology is the part of biology which deals with the relation between living organisms and their environment. There are two parts to the environment: the non-living or *physical*, and the living, or *biotic*. The life of plants and animals is most affected by the following elements in the physical environment: heat, light and water (as ice, liquid or vapor); chemicals, including oxygen, carbon dioxide, concentration of acid or alkali; general soil effects; air pressure; and wind, wave or current action. The action of winds, waves and currents are more important to distributing or in limiting the distribution of animals and plants than in limiting their growth.

Among the biotic or living elements we must mention:

(1) Food chains; that is, groups of animals, no one of which can be disturbed without upsetting the food relationships of the whole series. These are based principally on plants, but are organized about key-industry animals which make plant food available to a large number of other animals. Plant aphids are an example of key-industry animals, converting plant foods into such a form that they can be used by many animals. The aphids change plant juices into a secretion called honeydew, which is much used by ants and bees. They themselves are fed upon by many insects and by birds. Food chains include the whole range of food relations among animals—from the parasites that live upon the food or tissues of their hosts, to the hawks or foxes that prey upon defenseless mice, which in turn feed upon defenseless plants.

(2) Competition for space among animals is another biotic element in the environment.

(3) Coöperation among animals, as between the different members of an ant colony.

(4) The "web of life" is an expression covering all the biotic relations. Its far-reaching effects are illustrated by the well-known example used by Darwin to show that, in the country districts of England, the more old maids, the more clover seed. The relationships are: the more old maids, the more cats; the more cats the fewer mice; the fewer mice the more bumble bees; the more bumble bees, the more clover. Therefore the more old maids, the more clover seed.

Biotic factors, acting together, tend to bind the animals and plants in any place into a more or less organized community, which contains certain important plants or animals and which may also contain many more or less incidental forms. These communities undergo changes with increasing age of the environment, and these changes are called *succession*. Ecological succession may be illustrated in streams where certain fish, usually minnows, are found only in brooks at head waters; others are limited to the medium-sized creeks or rivers, while still others live only in large rivers. As the brook becomes deeper the larger fish move up in it, while the smaller fish move on to new headwaters.

In nature, animals and plants are usually in a rough balance. When for any reason one kind of animal becomes unduly abundant, its enemies also tend to increase in numbers until the over-abundant animal is killed off sufficiently to restore a new balance. Man greatly disturbs this natural balance by clearing off forests and planting large holdings of food plants which attract insects and other enemies. The problems arising from the depredations of these animals form the basis of economic zoölogy, which is one aspect of ecology.

Ecology emphasizes the following generalizations:

(1) The law of toleration: an animal or plant will tend to occupy all situations where it can tolerate the physical and biotic conditions, unless kept out by such impassable barriers as deserts, high mountain ranges or broad expanses of water.

(2) Toleration is lowest at the time of the breeding season and when animals are young; so that the range at breeding time is more restricted and becomes the most important part of the entire range of the animal. Thus, gulls retire to secluded islands to lay their eggs. Destruction of these nesting sites, or of the eggs or of young birds, will rapidly reduce the total number of gulls. This is one of the most important causes of the reduced numbers of wild animals in closely settled regions, and acts more rapidly than the killing off of the adults by hunting, fishing or trapping.

(3) In order to live in a given environment, animals must fit the conditions there in at least fifty-one per cent of their possible relations. In other words, animals must be at least fifty-one per cent adapted to their environment during each stage of their existence. If they are not so adapted, they either migrate or die.

There are many other important aspects of zoölogy, among which are *parasitology*, which deals with animal parasites; *genetics*, which treats of heredity and in which great progress has been made, particularly since the re-discovery of Mendelian heredity in 1900; *animal geography*, which is concerned with the distribution of animal life over the face of the earth; and *philosophical zoölogy*, which deals with the explanation of the zoölogical facts that have been accumulated.

ZOÖLOGICAL THEORIES

Organic Evolution. Modern zoölogy is organized around three great theories. The oldest of these is that of organic evolution, which dates back to Aristotle and the other Greek philosophers who flourished as early as the fourth century B. C. It holds that all species of animals and plants living today are descended from other species. According to Professor Lull of Yale, "Evolution is the gradual development from the simple unorganized condition of primal matter to the complex structure of the physical universe; and in like manner, from the beginning of organic life on the habitable planet, a gradual unfolding and branching out into all the varied forms of beings which constitute the animal and plant kingdoms. The first is called inorganic, the last organic evolution." There are numerous theories as to how organic evolution came about, the most famous of which is the Darwinian theory of evolution by natural selection, which implies that the fit-

test animals and plants survive. This was first clearly stated in 1859.

All Life from Previous Life. The next great theory of zoölogy was first proposed by William Harvey near the beginning of the seventeenth century. It holds that, for higher animals, all life comes from the egg. This has been broadened by three centuries of study to state that, so far as we know, all life now comes from previous life.

Cell Theory. The third is the cell theory. This was first fully stated in 1839 by two German workers, Schleiden and Schwann. It holds that all animals and plants are composed of cells. At present this generalization is regarded as fundamental both for structure and for physiology of living matter.

DICTIONARY OF ANIMALS

Adder (*Peliasbe rus*). A viper, widely distributed throughout Europe, the only British venomous snake. It attains a length of over two feet, is brown, with a black zigzag line down the back, feeds chiefly upon mice, and is viviparous (bears young alive—not from eggs). Its bite rarely proves fatal, except to very weak persons and children. In the United States the term is applied to some poisonous snakes without rattles, as the moccasin, or "water adder"; the copperhead, or "red adder," and also to the harmless hognose, which resembles in appearance and assumes the defensive attitude of a viper when it is disturbed.

Agouti (*Dasyprocta* spp.). A rodent, native of the West Indies, of South and Central America, and found as far north as Mexico. The agoutis live for the most part upon the surface of the ground, not climbing or digging to any great depth. They commonly sit upon their haunches when at rest, holding their food between their forepaws in the manner of squirrels. By eating the roots of the sugar cane, they are often the cause of great injury.

Albatross (*Diomedea* spp.). The albatross is the largest of all aquatic birds, the wings, when extended, measuring sometimes fifteen feet. Specimens often exceed twenty pounds in weight. Its plumage is white, with some black bands on the wings and back. It has a strong, hard, long beak, of a pale-yellow color; the feet, flesh-colored, are short and webbed, and the wings are long, strong and narrow. It secures its prey on the wing, and is very voracious. Many are continually met with in the Southern Ocean, and are also seen in immense flocks about Bering Strait in the early part of summer, attracted thither by the vast schools of fish whose migrations they follow. Their powers of flight are prodigious.

Alligator (*Alligator* spp.). A genus of reptiles closely resembling the crocodiles. Alligators are found only in the southeastern portions of the United States and China. They differ from the crocodiles in having a shorter and flatter head and in having cavities or pits in the upper jaw, into which the long canine teeth of the lower jaw fit. The feet are much less webbed. Although living for the most part in the water, the alligator is much less restricted to it than is the crocodile. The eggs are laid in small groups in the sand and hatched by the heat of the sun. Alligators occasionally reach a length of from seventeen to twenty feet.

Alpaca (*Lama huanacos*). The alpaca, one of the representatives of the camel group in the New World, is closely related to the llama. Its range is wholly in South America and is restricted to the higher portions of the Andes Mountains. The Peruvians keep vast flocks of alpacas, and esteem the silky luster and fineness of their wool, which furnishes material for the best of fabrics. See Llama.

Amoeba (*Amoeba* spp.). Microscopic animals consisting of a single cell and belonging to the lowest group of the animal kingdom. Their mode of locomotion is by flowing, which they do slowly and in any direction, the animal having no head or front end. A related species (*Entamoeba histolytica*) causes severe inflammations of the intestine, where it is sometimes found living parasitically.

Amphibians. A group of vertebrates containing such forms as the frog, toad, salamander and newt. The name means "double life" and was given because of the fact that these animals spend part of their life in the water and part on land. Breathing is done largely through the skin, although lungs or gills are usually present. The amphibians, although air breathers, are very rarely found away from the water where their eggs are laid and hatched. The young, after swimming around for some time, change their habits and become terrestrial for the rest of their lives. The amphibians have been called "batrachians" by some authorities. .

Anaconda (*Eunectes murinus*). The common name of one of the largest species of the serpent tribe. It is a native of tropical America and is allied to the boa constrictor. The anaconda, like the boa, kills its prey by wrapping its body around the victim and constricting. It lives in swamps and rivers, or in trees along river banks.

Anchovy (*Engraulis encrasicholus*). A well-known small fish of the herring family, abounding in many parts of the Mediterranean, particularly on the coasts of Italy, Greece, Spain and France. It is about four inches long, of a bluish-brown color on the back, and silvery-white on the belly. It was known to the ancients, and was used by both the Greeks and Romans as a pickle or sauce under the name of *garum*.

Ant. The common name of hymenopterous (or membranous-winged) insects of various genera, of the family *Formicidae*, found in most temperate and tropical regions. They are small but powerful insects, and have long been noted for their remarkable activities and interesting habits. They live in communities regulated by definite laws, each caste of the society bearing a well-defined and separate part in the work of the colony. Each community consists of males; of females much larger than the males; and of sterile females, otherwise called neuters, workers or nurses. The workers are wingless, and the males and females acquire wings only for their "nuptial flight," after which the males perish, and the few females divest themselves of their wings, and either return to established nests or become the founders of new colonies. The workers perform all the labors of the ant hill or abode of the community: they excavate the galleries, procure food, and feed the larvae or young ants, which are without organs of locomotion. In fine weather they carefully convey them to the surface for the benefit of the sun's heat, and as attentively carry them to a place of safety either when bad weather is threatened or the ant hill is disturbed. In like manner they watch over the safety of the nymphs, or pupae, about to acquire their perfect growth. Some communities possess a special type of workers, known as "soldiers," because of the duties that fall upon them. There is a very considerable variety in the materials, size and form of ant hills, or nests, according to the peculiar nature or instinct of the species. Some ants live on animal food, very quickly picking quite clean the skeleton of any dead animal they may find. Others live on saccharine matter, being very fond of the sweet substance, called "honey-dew," which exudes from the bodies of aphids or plant lice. These they sometimes keep in their nests, and sometimes tend on the plants where they feed; sometimes they even superintend their breeding. By stroking the aphids with their antennae they cause them to emit the sweet fluid, which the ants then greedily imbibe. Various other insects are found living with ants in different types of association. It has been observed that some species, like the red ant (*Formica sanguinea*), resort to violence to obtain working ants of other species for their own use, plundering the nests of suitable kinds of their larvae and pupae, which they carry off to their own nests to be carefully reared and kept as slaves. In temperate countries most of the male and female ants survive until cold weather. The next brood of ants appears in the spring from eggs laid the preceding summer. The workers, in the colder climates, pass the winter in a state of torpor, and of course require no food. The only time when they require food is during the season of activity, when they have a vast number of young to feed. Some species have stings as weapons, others only their powerful mandibles or an acrid and pungent fluid (formic acid) which they can emit.

Anteater (*Edentata*). Animals with long hair and very slender heads, which walk on the sides of their feet with the claws incurved. They have no grinding teeth, their food being captured by a long tongue which the animal is able to extend for considerable distances.

The great anteater, *Myrmecophaga jubata*, is a native of Brazil and Guiana, and is much the largest of all the anteaters. It is covered with long, coarse, shaggy hair, and has a remarkably large tail with which, when at repose, it can wrap itself up as so to be effectually protected from heat or rain. It is a powerful animal, and specimens often occur which measure more than eight feet in length from the extremity of the nose to the end of the tail. It lives exclusively on ants, and procures these insects in abundance by tearing open their hills with its hooked claws, and then drawing its long tongue, which is covered with glutinous saliva, over the swarms which flock from all quarters to defend their dwelling.

Antelope (*Antilopinae*). The common term for a number of species of graceful deer-like animals. They have a timid and restless disposition. Antelopes are among the swiftest runners in the animal kingdom. Externally, they very much resemble deer, from which, however, they are to be distinguished by various points of structure, such as the horns, which in the deer are solid and branched, and by the absence of front teeth in the upper jaw. Generally speaking, antelopes are gregarious, and unite in large flocks or herds. Africa may be considered the headquarters of the antelope. The species are numerous, and include the springbok, hartebeest, gnu, eland and gazelle. There are two European antelopes, the chamois, which inhabits the Alps, and the saiga, from eastern Russia.

Ant Lion (*Myrmeleonidae*). The larva of a neuropterous insect, the adult of which resembles a dragon fly. Ants form most of the prey, hence the name, ant lion. The larva is interesting because of the curious way in which it catches its food. It digs a funnel-shaped hole in the driest and finest sand it can find, and when the pit is deep enough, and the sides are quite smooth and sloping, it buries itself at the bottom with only its formidable mandibles projecting. Then it waits until some luckless insect stumbles over the edge, when it is immediately seized, its juices sucked, and the dead body thrown out.

Ape (*Simiidae*). A name given to the most highly developed monkeys. They are all inhabitants of the Old World. The nostrils are divided by a narrow septum; they possess opposite thumbs on their fore and hind feet; the callosities on the rumps are generally naked. Some of the species only are furnished with cheek pouches. The family is divided into two groups, (1) the tailless, or true apes, comprising the chimpanzee, the gorilla and the orang-utang and (2) the tailed monkeys, including all he true monkeys of the Old World.

Aphids (*Aphidoidea*). Small insects known as plant lice which feed on the juices of plants. Many species excrete a substance called "honeydew," which is food for bees and ants. Some ants keep aphids in their nests and care for them in order that they can use the honeydew. These aphids in ant nests are known as "cows." See Ant.

Armadillo (*Dasypus* spp.). A mammal, found in South America and in North America as far north as Texas, belonging to a family intermediate between the sloths and anteaters. They are covered with a hard bony shell, divided into belts, composed of small separate plates like a coat of mail, flexible everywhere except on the forehead, shoulders and haunches, where it is not movable. The belts are connected by a membrane, which enables the animal to roll itself up like a hedgehog. These animals burrow in the earth, where they lie during the daytime, seldom going abroad except at night. They are of different sizes; the largest, *Dasypus gigas*, being three feet in length without the tail, and the smallest only ten inches. They subsist chiefly on fruits and roots, sometimes on insects and flesh. They are inoffensive, and their flesh is considered good food.

Arthropods. An enormous group of the animal kingdom, including the crayfishes, crabs, spiders, insects, centipedes, and many other animals with jointed legs and segmented bodies. There are more species of arthropods than of all the other groups combined. Many are of great economic importance.

Ass (*Equus asinus*). A species of the horse genusl supposed by Darwin to have sprung from a wild variety found in Abyssinia. Some writers consider it to be a descendant of the onager, or wild ass, inhabiting the mountainous desert of Tartary. Others believe that it descended from the kiang of southwestern Asia.

Both in color and size the ass is exceedingly variable, ranging from dark gray and reddish brown to white, and from the size of a Newfoundland dog as in northern India, to that of a good-sized horse. In the southwestern countries of Asia and in Egypt, in some districts of southern Europe, as in Spain, and in Kentucky and Peru, great attention has been paid to selection and interbreeding, with a result no less remarkable than in the case of the horse. Thus in Syria there appear to be four distinct breeds—a light and graceful saddle animal used by ladies, an Arab breed reserved for the saddle, an ass of heavier build in use for plowing and draft purposes, and the large Damascus breed.

Auk (*Alcidae*). The common name of several swimming birds, including the great auk, the little auk and the puffin. The great auk, a bird about three feet in length, is now extinct, the last survivors having been killed about 1845. Auks are almost wholly water birds, coming to land only in times of great danger, and in the breeding season. The food seems to be mainly fishes, crustaceans and worms. Auks are northern birds, ranging from Newfoundland to Iceland in the Atlantic, and from California to the Bering Straits in the Pacific.

Axolotl (*Amblystoma maculatum*). A curious Mexican amphibian, not unlike a newt, from eight to ten inches in length, with gills formed of three long ramified or branchlike processes floating on each side of the neck. It reproduces by laying eggs, and was for some time regarded as a perfect animal with permanent gills. It is said, however, that it frequently loses its gills like the other members of the genus. The axolotl is esteemed a luxury by the Mexicans. There are a number of species in North America.

Babiroussa (*Babirusa* spp.). A hog-like animal inhabiting some of the islands of the East Indies. The body is almost without hair and the animal is equipped with long tusks which extend from the jaws.

Baboon (*Cynocephalus*). A common name applied to a genus of the monkey group. They have elongated, abrupt muzzles like a dog, strong tusks or canine teeth, usually short tails, cheek pouches, small deep eyes with large eyebrows, and naked callosities on the buttock. Their hind and fore feet are well proportioned, so that they run easily on all fours, but they do not maintain themselves in an upright posture with ease. They are generally of the size of a moderately large dog; but the largest, the mandrill, is, when erect, nearly of the height of a man. They are almost all African, ugly, sullen, fierce and gregarious, defending themselves by throwing stones and dirt. They live on fruits, roots, eggs and insects.

They include the chacma, drill, common baboon, and mandrill. The chacma, or pigtailed baboon, (*C. porcarius*) is found in considerable numbers in parts of South Africa. The common baboon (*C. babouin*) inhabits a large part of Africa farther to

the north. It is of a brownish-yellow color, while the chacma is grayish black, or in parts black. The hamadryas (*C. hamadryas*) of Abyssinia is characterized by long hair, which forms a sort of shoulder cape. The black baboon (*C. niger*) is found in Celebes.

Badger (*Mustelidae*). The American badger (*Taxidea* spp.), is generally regarded as a solitary, stupid animal. Its length averages about two and one-half feet. The forepaws are provided with immense claws, indicating a burrowing habit. The badger is unique in having the hind limbs the same length as the fore limbs. It lives chiefly on roots, fruits, insects, squirrels and frogs. Some consider the flesh of the badger a delicacy, and cure it into bacons and hams.

Banteng (*Bos sondaicus*). A species of wild cattle inhabiting the Malay region of Asia. The head is noticeably elongated.

Barbet (*Capitoninae*). Sub-family of climbing birds with thick, conical beaks, having tufts of bristles at their base. Their wings are short and their flight somewhat heavy. They have been divided into three subgenera—the barbicans, inhabiting India and Africa, and feeding chiefly on fruit; the barbets proper, found in Africa and America, and nearly related to the woodpeckers; and the puffbirds, inhabiting America, and feeding on insects.

Barnacle (*Cirripedia*). A group of marine Crustacea, commonly found in great numbers on rocks, timber, ships' bottoms and in similar places in all parts of the world. The body is enclosed in a shell of five valves, which may be closed when the animal is out of the water. Some barnacles are provided with a long stalk, or peduncle, by which they attach themselves to the rocks. When the shell is open, long arms or tentacles stick up and pick food out of the water. Barnacles begin their lives by swimming freely in the water, but soon degenerate and settle down in one place for life.

Bat (*Chiroptera*). A group of wing-handed, flying mammals having the forelimb peculiarly modified to serve for flight. Bats are animals of the twilight and darkness, and are common in temperate and warm regions, but are most numerous and largest in the tropics. All European bats are small, and have a mouse-like skin. The body of the largest British species (*Vespertilio noctuula*) is smaller than that of a mouse, but its wings stretch about fifteen inches. During the day it remains in caverns, in the crevices of ruins, hollow trees and similar lurking places; at evening it flits out in search of food, which consists of insects. Several species of the same genus are common in North America. Many bats are remarkable for having a singular nasal cutaneous appendage, bearing in some cases a fancied resemblance to a horseshoe. Two of these horseshoe bats are found in Britain.

Bats may conveniently be divided into two sections—the insectivorous or carnivorous, comprising all European and most African and American species, the fruit-eating, belonging to tropical Asia and Australia, and several African forms. An Australian fruit-eating bat, the kalong or flying fox, is the largest of all the bats; it does much mischief in orchards. At least two species of South American bats are known to suck the blood of other mammals, and hence are called "vampire bats." The best known is the *Desmodus rufus* of Brazil.

As winter approaches, in cold climates bats seek shelter in caverns, vaults, ruined and deserted buildings, and similar retreats, where they cling together in large clusters, hang head downward by the feet, and remain in a torpid condition until the returning spring recalls them to active exertions.

Batrachians. See Amphibians.

Bear (*Ursus* spp.). The name of several large carnivorous animals. The true bears are about ten in number, natives chiefly of Europe, Asia and North America. They generally lie dormant in their dens during the winter months.

The brown or black bear of Europe is the *Ursus arctos*. It is a native of almost all the northern parts of Europe and Asia, and was at one time common in the British islands. It feeds on fruits, roots, honey, ants and, in case of need, on mammals. It sometimes reaches the length of seven feet, the largest specimens being found farthest to the north. It lives solitarily.

The American brown or black bear is *Ursus americanus*, with black shining hair, and rarely above five feet long. It is a great climber, is less dangerous than the grizzly bear, and is hunted for its fur and flesh. It is very amusing in captivity. The grizzly bear (*U. ferox* or *U. horribilis*) is an inhabitant of the Rocky Mountains; it is a ferocious animal, sometimes nine feet in length, and has a bulky and unwieldy form, but is nevertheless capable of great rapidity of motion.

The extinct cave bear (*U. spelaeus*) seems to have been closely akin to the grizzly. The Siberian bear (*U. collaris*) is perhaps a variety of the brown bear. The polar or white bear (*U. maritimus*) is characterized by its flat head and comparatively long neck.

Beaver (*Castor* spp.). A member of the gnawing mammals, or rodents. It has a broad, flat, naked tail, and webbed hind feet, fitting it for life in the water. It is very widely distributed, being found in the northern parts of Europe, Asia and America, most abundantly in the northern and thinly peopled parts of North America, dwelling in communities on the banks of rivers and lakes. The beaver dam is one of the most famous of all animal enterprises. At one time immense numbers of these animals were killed for their fur, which was largely used in making hats. Within recent years, beaver fur has had wide use in the making and trimming of women's coats.

Bee (*Hymenoptera*). A well-known group of insects, relatives of the ants, wasps and gallflies.

Man appears from the very earliest ages to have known the value of bees, and to have taken advantage of their products. The Bible makes mention of honey-bees, and the Latin poet, Virgil, has celebrated them in the fourth book of his *Georgics*, where he has summed up all that the ancients knew about them.

During the greater part of the year the population of bee hives is composed exclusively of two sorts of individuals, the female or mother bee, the queen bee, and the working bees, or neuters, which are, properly speaking, females imperfectly developed. A third kind of individuals, the males or drones, are generally not met with except from May to July.

The working bees constitute essentially the bee community; they are recognized by their small size, reddish-brown color and, above all, by the palettes and brushes with which the hind legs are furnished. The three pairs of legs, which are inserted in the thorax, or chest, of the bee, are its tools. The two hind legs are longer than the other pairs, and present on the exterior a triangular depression, resembling and called a "palette," which is surrounded by stiff hairs, forming the borders of a sort of basket in which the insect deposits the pollen of flowers. To each of these hind legs is jointed a square expanded piece, which might be termed the ankle, smooth on the exterior, but having hairs on its interior surface which has caused it to be named the "brush," and which is employed in collecting the pollen. The other tools of the working bee consists of a pair of movable mandibles, which close the mouth on its two sides, and of a trunk, or proboscis, which may be considered as a sort of tongue. This latter organ has a hairy surface, to which the honey of flowers adheres, whence it is conveyed to the mouth, and from it to the stomach, to be subsequently disgorged.

The males, or drones, are larger and more hairy than the working bees; they emit a buzzing sound, have no palettes, and do not sting. The female, or queen, has a longer body than the workers, and the wings are shorter in proportion. The only part she has to play is that of laying eggs, and so she has no palettes or brushes. Only one queen lives in each hive, of which she is perfect sovereign, all the workers submissively obeying her.

The number of males is scarcely one-tenth that of the working bees, and they live only about three months.

The wax of which the cells of the honeycomb are constructed is supposed to be secreted by an organ situated in the abdomen, or belly, of the bee; but, in addition to wax, another substance, much resembling it, but not identical, called "propolis," is made from the juices of certain plants, and used to line the inner surface of the hive. The cells are six sided in shape, and are of two kinds, namely, store cells, which are filled with honey, as a reserve store of food, and cradle cells, in which the eggs are laid.

At a certain time of the year the queen leaves the hive, accompanied by the drones, and takes what is called her "nuptial flight" through the air. About forty-eight hours after her return to the hive she begins laying her eggs, at the rate of about 200 a day. The eggs which are destined to develop into workers are first laid, then those which are to produce males, and lastly those which give birth to females. The eggs hatch early and the larvae, or caterpillars, which emerge from them are tended by the workers, and fed by them on a peculiar paste, which is apparently a preparation of pollen. In five or six days the larvae pass into the condition of pupa, or chrysalis, and seven or eight days later the adult insect is hatched.

Beetle (*Coleoptera*). Insects, commonly but wrongly called "bugs," in which the wings are covered by hard, tough covers which fit tightly together along the back and protect the wings when the animal is not flying. Beetles are found in all types of places from forests to deserts. Many bore in wood and live in tunnels under the bark of trees, while others are found only on flowers. Still other species are restricted to the remains of dead animals. Many pests, such as the weevils, belong to this group.

Bighorn (*Ovis montana*). A species of wild sheep which inhabits the western mountain ranges of North America from New Mexico and California northward to British Columbia. The horns are curved and measure about thirty-two to forty inches in length. See Sheep.

Bird of Paradise (*Paradiseidae*). This group contains some of the most beautifully colored birds that are known. In addition to the great splendor of color, many are provided with plumes and feathers of most unusual shape.

Bison (*Bison* spp.). A genus of ungulates (hoofed animals), one species of which (*B. europaeus*) is found only in the forests of Lithuania and in the Caucasus. The other species, the American bison (*B. americanus*), was formerly found in great numbers on the western plains of North America, but is now present only in a few herds that are protected by law.

The two species closely resemble each other, the American bison, however, being for the most part smaller, and having shorter and weaker hind quarters. The bison is remarkable for the great hump or projection over its fore shoulders, at which point the adult male is almost six feet in height, and for the long, shaggy rust-colored hair over the head, neck and forepart of the body. In summer, from the shoulders backward, the surface is covered with a very short, fine hair, smooth and soft as velvet. The tail is short and tufted at the end.

The American bison used to be much hunted for the sake of mere sport as well as for its flesh and skin. Its flesh is rather coarser grained than that of the domestic ox, but was considered by hunters and travelers as superior in tenderness and flavor. The hump is highly celebrated for its richness and delicacy. Bison skins, especially that of the cow, dressed in the Indian fashion, with the hair on, make admirable defenses against the cold, and are known as "buffalo robes"; the wool has been manufactured into hats, and a coarse cloth has also been made from it. The American bison has been found to breed readily with the common ox, the issue being fertile among themselves.

Bittern (*Botaurinae*). Water birds which inhabit marshy places. There are two British species, both of which are becoming rare because of the reclamation of the marshy grounds that form their favorite haunt. The common bittern is about twenty-eight inches in length, and about forty-four in extent of wing; its general color is a dull yellowish-brown, with spots and bars of black or dark brown; it has long and loose feathers on the breast; a short tail and a bill about four inches long. It is remarkable for its curious booming or bellowing cry, from which come the provincial names of "miredrum" and "butterbump." The eggs are four or five in number. The little bittern is not more than fifteen inches in length. The American bittern (*Botaurus lentiginosus*) has some resemblance to the common European bittern, but is smaller.

Blackbird (*Merula merula*). A well-known species of thrush, common in England and throughout Europe. It is larger than the common thrush, its length being about eleven inches. The color of the male is a uniform deep black, the bill being an orange-yellow; the female is of a brown color, with blackish-brown bill. The nest is usually in a thick bush, and is built of grass, roots and twigs, strengthened with clay. The eggs, generally four or five in number, are of a greenish-blue, spotted with various shades of brown. The song is rich, mellow and flute-like, but of no great variety or compass. Its food is insects, worms, snails and fruits. The blackbirds, or crow blackbirds, of America are quite different from the European blackbird, and are more nearly allied to the starlings and crows. The red-winged blackbird (*Argelaius phoeniceus*), belonging to the starling family, is a familiar American bird that congregates in great flocks.

Bluebird (*Sialis sialis*). A small bird, very common in the United States. The upper part of the body is blue, and the throat and breast is an earthy red. It makes its nest in the hole of a tree or in the box that is so commonly provided for its use by the friendly farmer. The bluebird is the harbinger of spring; its song is cheerful, continuing with little interruption from March to October, but is most frequently heard in the serene days of the spring.

Boa (*Boidae*). South American snakes with jaws so constructed that they can dilate the mouth sufficiently to swallow bodies thicker than themselves. They are also distinguished by having a hook on each side of the vent; the tail prehensile; the body compressed and largest in the middle, and with small scales, at least on the posterior part of the head. The genus includes some of the largest species of serpents—reptiles endowed with immense muscular power. They seize sheep and deer and crush them in their folds, after which they swallow the animal whole. The boas are peculiar to the hot parts of South America. The boa constrictor is not one of the largest members of the genus; it rarely exceeds twenty feet in length; but the name boa or boa constrictor is often given popularly to any of the large serpents of similar habits, so as to include the pythons of the Old World and the anaconda and other large serpents of America.

Boll Weevil (*Anthonomus grandis*). A beetle which lays its eggs in cotton bolls. The larva, when hatched, destroys the boll and causes great damage wherever cotton is grown. This pest was formerly restricted to Central America, but it has greatly extended its range. It entered Texas about 1890, from which it spread over the cotton-growing states of the United States.

Bony Pike (*Lepidosteus* spp.). A remarkable genus of fishes inhabiting the rivers and lakes of North America, and one of the few living forms that now represent the order of Ganoid fishes so largely developed in past geological ages. The body is covered with thick, smooth, rhomboid scales, so hard that it is almost impossible to penetrate them with a spear. The common garfish (*L. osseus*), whose distribution is rather general over the inland waters of eastern North America, sometimes attains a length of five feet, and is easily distinguished by the long extension of the mouth region to form a beak-like structure.

Buffalo (*Bos* spp.). A name of certain wild cattle of the warmer parts of the Old World, living in marshy places. Some of them have been domesticated and are used as beasts of burden. The name was transferred by the early explorers to the bison of North America, a very different kind of animal. When first discovered America had the bison as far east as Ohio, while farther west they occurred in enormous herds. With the opening of the transcon-

tinental railroads these herds were quickly killed off, so that now there are only a few protected herds. The attempt has been made, with some success, of crossing them with domestic cattle. See Bison.

Bug. A name loosely applied to any insect, but rightly belonging to insects of the order *Hemiptera*, which have sucking mouthparts and the wings partly hardened, partly membranous. Most of them feed on the juices of plants which they suck by means of the beak, but a few prey upon other animals, the bedbug attacking man. Most of the group are pests, like the squash bug, the plant lice and the scale insects; but a few are of value, like the lac insects and the cochineal, the former furnishing the shellac, the latter the carmine.

Bullhead. A common name for several species of fish. In the United States the name is given to some species of catfish or horned pout; in England to a smaller fish, allied to our miller's thumb, but belonging to a different group from the catfish.

Butterfly (*Lepidoptera*). A group of insects with broad wings, easily distinguished from the moths by their habit of flying in the daytime and by having the antennae or feelers at the end of the head ending in a club, and never tapering or feathered. Like many other insects, butterflies hatch from the egg with a shape like a worm, the larva or caterpillar. The larva eats mostly vegetable matter, grows rapidly, molts its skin several times, and at last changes into a resting stage, the pupa or chrysalis, which usually passes the winter. Then the pupa case splits down the back and from the opening the butterfly comes out to lead a short life, during which it lays the eggs which are to go through the same history. There are several thousand species of butterflies known, the majority being inhabitants of the tropics.

Buzzard (*Falconidae*). A name applied to several daytime birds of prey closely resembling the hawks, our common hen hawk being a buzzard. These birds feed on mice, moles, small birds and insects and on the whole are therefore a benefit to the agriculturist. The common buzzard is spread over the whole of Europe and America. The carrion buzzards feed on decaying animal matter; the bee buzzards or honey buzzards of the Old World feed on honey and on the larvae of bees and wasps.

Caddisfly (*Trichoptera*). Small insects with rather delicate wings, found in great numbers near lakes and streams. They are easily attracted to artificial light. The larvae enclose themselves in nets or cases. These cases are usually placed in swift streams and turned so that food can be washed into an opening in the case. The larvae are important as food for fish.

Camel (*Camelus* spp.). Well-known animals which are found in Africa and Asia. The Asiatic camel (*C. bactrianus*) has two humps, while the African camel (*C. dromedarius*) has only one. Camels are valuable animals, as they can go for a long time without water. For this reason they are much used in transportation across the deserts. The alpaca and llama of South America are closely related to the camels of the Old World.

Canary (*Serinus canarius*). Small finches, native to the Azores, Canary and Madeira Islands, but domesticated in many countries for 300 years. Because of their power of song, canaries are sold as household pets, the best singers bringing high prices. While the usual color in cage birds is yellow, the wild birds are a dull green.

Cardinal (*Cardinalis cardinalis*). The cardinal, or redbird, is one of the most beautiful of all the American song birds. The color is brilliant red, and a sharp crest of vermilion gives the bird a striking contrast to the green foliage of the trees. The cardinal nests in bushes and thickets, and constructs its nest of bark and twigs.

Caribou. See Reindeer.

Carnivores. A group of mammals in which the canine teeth are well developed. The carnivores feed mostly on other animals. Such forms as dogs, cats, lions, seals, bears, hyenas, coyotes and badgers are members of this group, which is natively one of the most ferocious in the animal kingdom.

Carrier Pigeon (*Columbae*). A race of pigeons in which the homing instinct is well developed. These pigeons may be taken miles from home, but manage to fly back, even under the most trying conditions. For this reason they were formerly used by travelers to send messages home.

Cassowary (*Casuariidae*). A peculiar bird of Australia, having very rudimentary wings and a long neck. It is closely related to the rhea and emu.

Cat (*Felidae*). A large family of animals, including the lion, tiger, panther, leopard, lynx, puma, and a number of other forms, among them our domestic cat. All have retractile claws, cutting molar teeth and elongate pupils to the eyes. The common cat is probably a native of Egypt. It is certain that it was domesticated there and that it was an object of worship and was frequently mummied. It was not known to the ancient Greeks and Romans, its place as a destroyer of rats and mice having been taken by domesticated martens.

Domestic cats are cleanly animals, more attached to places than to persons, and, like many domesticated animals, are variable in color. Besides the ordinary kinds, there are common the tailless Manx cats (coming from the Crimea as well as from the Isle of Man) and the Angora or Persian cats, with long silky fur. The original of the domestic cat was probably marked with black bars on a ground of tawny and white, these colors rendering them inconspicuous among the grasses and shrubbery where they ranged.

Catbird (*Turdidae*). A well-known species of American thrush, which, during the summer, is found throughout the Middle and New England States. The plumage is a deep slate color above, and lighter below. The catbird is about nine inches long. In habit it is lively, familiar and unsuspicious; the song is largely imitative of those of other birds, but it also has the cat-like note which gives it its common name. During the winter it inhabits the extreme south of the United States, and is found also in Mexico and Central America.

Caterpillar. The worm-like larva of moths and butterflies. They are often mistaken for true worms, which have the same general shape and mode of locomotion. Caterpillars often do great damage to crops and other vegetation by eating leaves. The silkworm is an economically valuable caterpillar which spins a cocoon from which silk is made.

Cattle (*Bos* spp.). Well-known animals of world-wide distribution, whose appearance and habits are familiar. There are many breeds of domestic cattle. In India and other southern Asiatic countries, the zebu is used in much the same way as our domestic cattle are used in this country. Zebus are humped cattle, and are not of the same quality as American or European breeds. The European cattle, which have been introduced into America, are of two general types, the beef type and the dairy type. Of the beef cattle, the English Shorthorns are a very sturdy breed. These vary from red to almost pure white. Shorthorns originated in England, but later spread to North and South America and to Australia. Another valuable beef variety is the Hereford. This has a red body and white head. Herefords are not so widely distributed as Shorthorns. Among the dairy cattle, the Holstein breed is perhaps the most important. Holstein cattle are great milk producers, but the percentage of butter fat is somewhat less than in other cattle. This variety originated in Holland, but has been imported to a considerable extent to this country and now forms an important part of the milk industry. Jersey cattle are also good dairy animals. These are of various shades of yellow and red. Jersey milk is rich in butter fat. This breed originated on the Isle of Jersey, off the coast of France. Guernsey cattle are reddish, with white markings. They also originated on an island near France. Their milk is probably the richest in fat, but the quantity is not so great as in other breeds. Among the wild cattle, the American bison (see Bison) is native to this country. For wild cattle of other countries, see Yak and Banteng.

Cavy. See Guinea Pig.

Centipede (*Myriopoda*). A group of segmented animals, closely related to the insects, but having legs on every segment. They are further distinguished by the fact that, except for the first and last few segments, all are essentially alike. Most of the North American species are small and inconspicuous, living under stones and in and under decaying logs. In the tropical regions, however, they attain greater sizes, sometimes reaching ten inches in length. Some centipedes are provided with poison glands, the contents of which causes considerable pain to a person bitten, although known cases of death are rare.

Chameleon (*Rhiptog ossi*). A reptile, living in various parts of Asia, Africa and Europe. The best-known species has a naked body six or seven inches long, with a prehensile tail of about five inches, and feet suitable for grasping branches. The skin contains small grains of a bluish-gray color in the shade, but in the light of the sun all parts of the body become of a grayish-brown or tawny color. It possesses the curious faculty of changing its color either in accordance with its environment, or with its temper when disturbed, the change being due to the presence of clear or pigment-bearing contractile cells placed at various depths in the skin, their contractions and dilations being under the influence of the nervous system.

Some lizards have the same power of changing color and the name has also been applied to them. Their power of fasting and habit of inflating themselves gave rise to the fable that they lived on air, but they are in reality insectivorous, taking their prey by rapid movements of a long, viscid tongue. In general habit they are dull and torpid.

Chamois (*Rupricapra* spp.). Goat-like antelopes inhabiting high, inaccessible mountains in Europe and western Asia. The horns, which are about six or seven inches long, are round, almost smooth, perpendicular and straight until near the tip, where they suddenly terminate in a hook directed backward and downward. The hair is brown in winter, brown fawn color in summer, and grayish in spring. The head is pale yellow with a black band from the nose to the ears and surrounding the eyes; the tail is black. Its agility, the nature of its haunts, and its powers of smell render the pursuit of the chamois an exceedingly difficult and hazardous occupation.

Chimpanzee (*Anthropopithecus* spp.). The native name, in Guinea, of a large ape of west and central Africa belonging to the anthropoid or man-like monkeys, and a close relative of the gorilla. When full grown it is sometimes about five feet high, with black hair, and is not so large and powerful as the gorilla. It walks erect better than most of the apes. It feeds on fruits, often robs the gardens of the natives, and constructs a sort of nest among the branches. It is common in menageries, where it shows much intelligence and docility.

Chinch Bug (*Lygaeidae*). An insect pest which feeds on the roots of plants, especially grain. In the wheat fields this pest destroys annually thousands of dollars worth of grain. The adults spend the winter by burrowing under the soil and seeking protection near the roots. They emerge in the spring and lay eggs, which hatch in about two weeks. When the young hatch they immediately start to feed. After about three months the adult stage is reached, and the animals lay eggs for a second brood. One of the best methods of control is by means of a fungus (*Sporotrichum globuliferum*) which causes a disease of the chinch bugs.

Clam (*Pelecypoda*). Bivalve molluscs which inhabit both fresh and salt waters, but which occur in far greater numbers in the ocean. Most clams live under the surface of the ground and send two long tubes to the surface, through which fresh water is taken in, and used water is eliminated. Others attach themselves to wharf piles or other places by means of tough threads which they secrete. The clams, as a group, are of considerable importance. The shipworm, which is really a clam, causes a great amount of damage by boring into ships and docks. The oyster, which is also a clam, is an important article of food. Many clams form pearls, of which those from Persia are probably the most valuable. In the United States, an important industry has grown up around the fresh-water clams, from whose shells are manufactured such articles as knife handles and buttons.

Cobra (*Naja tripudians*). An Asiatic snake, much used by snake charmers, who remove the teeth so that the animal is harmless. When irritated, the cobra has a habit of raising its head above the ground, puffing the region about the neck and swaying back and forth.

Cochineal Bug (*Coccus cacti*). An insect which feeds on cactus, and from whose dried bodies the cochineal dye was formerly made. In recent years the same dye has been obtained from coal tar. A related species, the lac bug (*Tachardia lacca*), secretes a substance from which shellac and several dyes are prepared. The chief industry is in India.

Cockroach (*Blattidae*). Insects which feed upon decaying vegetable matter. Several species have taken up their abode with man, and prove most unwelcome boarders. Many methods have been advocated for their extermination, but none is very satisfactory except the killing of every individual.

Cod (*Gadus callarias*). A valuable food fish of the North Atlantic, a near relative of the haddock. See Haddock.

Coelenterates. A large group of water animals containing such forms as the jellyfish and sea anemone. They are mostly sea animals, but a few are found in fresh water. The group is characterized by the presence of stinging cells, small structures that explode when the animal is irritated and cause severe irritation to the region of the body of an animal that they strike.

Colugo (*Galeopithecus volans*). A flying mammal of the Orient, related to the moles and shrews. Its head is dog-like, and a flap of skin extends from the neck to the tail, extending between the legs, much like the skin flaps of the flying squirrel. Colugos are about eighteen inches in length. They feed on seeds, fruits and leaves. They are quite helpless on the ground, but are active in the trees where they leap from branch to branch with remarkable agility.

Condor (*Sarcorhamphus gryphus*). A South American bird, one of the largest of the vultures. It resembles the common vultures, differing from them mainly in the large cartilaginous outgrowth which surmounts its beak, and in the large size of its oval and longitudinal nostrils. Despite stories of its gigantic proportions, Humboldt met with no specimens whose wings exceeded nine feet in expanse, though they have been known to expand to fourteen feet. Condors are found in the Andes Mountains, frequenting regions from 10,000 to 15,000 feet above the level of the sea. They descend to the plains only under stress of hunger, when they attack sheep, goats, deer and bullocks. They prefer dead animals.

Cony. A hare, especially the European *Lepus cuniculus* (see Hare). The hyrax (which see).

Coot (*Rallidae*). Water birds of wide distribution. The nest is built in the water by piling up masses of vegetation. Coots, although good flyers, do not leave the water unless disturbed. They have some difficulty in rising from the surface, due to the small size of their wings, and would rather dive than fly.

Coral (*Anthozoa*). Small marine animals which secrete limy skeletons, the commercial name for which is also coral. This skeleton is secreted by the outer surface of the animal and may show a number of little cups in which the animals live. When the animals die, the skeletons are left behind, and so abundant are they in the tropics that coral reefs and islands are formed by them. The precious coral of the Mediterranean and of Japan is very solid and takes a high polish. The price is dependent upon the color and size of the pieces, the pale pink commanding the highest price. Purchasers should beware of counterfeits made of marble, and of dyed coral.

Cormorant (*Phalacrocorax* spp.) Birds of eastern North America and western Europe, common along the seashore and sometimes found on inland lakes. They dive and swim easily. These birds usually nest in cliffs. Their food consists mostly of fish.

Corn-Borer, European (*Pyrausta nubilalis*). A

caterpillar, native to Europe and now a pest in America, which prefers the corn plant in which to bore and spend the winter. Great damage is done each year by this insect, and many efforts are being made to check its spread. It is important to destroy all infected material. Fermentation in silos kills the insect. Communication with the government or an agricultural college is advised to determine the best control measures.

Cowbird (*Molothrus* spp.). Birds so named because they are often seen around cows, on whose backs they frequently perch. The eggs are laid in the nests of other birds and left there to be hatched by the other birds.

Coyote (*Canis latrans*). A wolf-like animal of nocturnal habits found on the western plains of North America. It is smaller than the wolf and more cowardly. Its food consists mostly of rabbits, ground squirrels and other small mammals.

Crab (*Crustacea*). Marine animals in which the abdomen is small and folded under the anterior part of the body—the cephalothorax. Over two thousand species are known, differing greatly in size, shape and in other respects. The great majority are marine, but there are a few which spend their entire life on land, only going to the water once a year to lay their eggs. The largest is the great spider crab of Japan, whose legs may stretch out a dozen feet. Like all crustaceans, the crabs molt their shell at intervals, and after the molt, their skin is soft. One species on the Atlantic coast is taken at this time in great numbers and forms the favorite soft-shell crab of the table. The hermit crabs have the abdomens soft, and to protect this part, they carry it in the shell of a dead snail.

Crane (*Grallae*). A group of long-legged birds, remarkable for their long migrations, in which they usually fly in large flocks led by a single leader, the whole assemblage assuming a V form. The leadership is continually changed. The common crane breeds in the north of Europe and in Siberia, and migrates southward at the approach of winter. It attains nearly five feet in height; with the exception of the neck, which is black, the body is of a uniform ashy-gray; it has a graceful carriage. It frequents large plains and marshes, and feeds on fish, reptiles, frogs, molluscs, worms, insects, and even on small mammals. At the breeding season the birds pair for reproduction and rearing the young. Two species occur in America, the whooping crane being noticeable for the convolutions of the trachea within the breast bone.

Crocodile (*Crocodilia*). A group containing the largest living reptiles. The characters of the order *Crocodilia* are as follows: The skin is covered with square, bony plates; the tail is long and compressed; the feet are short, and there are five toes on each forefoot, and four on each hindfoot, the latter more or less webbed; the jaws are long and their gape enormous; the nostrils are at the extremity of the snout, and capable of being closed to prevent ingress of water; the heart is four-chambered.

The families now existing are the alligators, crocodiles and gavials. The alligators are confined to the southeastern parts of the United States and of China. The gavial proper is confined to the East Indies. The crocodile of the Nile is the best-known member of the order; another species is met with in southern Asia, and a third in tropical America. The crocodile is formidable from its great size and strength. It is exclusively carnivorous, and always prefers its food in a state of putrefaction. In Egypt it is no longer found except in the upper or more southern parts. It grows sometimes to a length of thirty feet, and apparently lives to a very old age.

Crow (*Corvidae*). The family, widely distributed over the world, includes the common crow, the raven, the fish crow, the rook, the jay and the magpie. The common crow of North America is remarkable for its gregarious and predatory habits, as well as for its intelligence and cunning. They pair in March; the old repair their nests, the young frame new ones; but they are such thieves that while the one is fetching materials the other must keep watch to prevent the rising fabric from being plundered by crow neighbors. As soon as the nest is finished and the eggs produced (five, bluish-green, with dark blotches), the male takes upon himself the care of providing for his mate, which he continues during the whole period of incubation. They frequent the same rookeries for years, but allow no intruders in to their community. They feed chiefly on worms and the larvae of insects, consequently during outbreaks of certain insects the crows are beneficial. They also eat grain and seeds, and are thus injurious to the farmer. Chiefly because they destroy beneficial wild birds and their eggs, crows must be classed as enemies.

Crustaceans. One of the great groups of animals with external skeletons and jointed feet, including the lobster, crab, barnacle and shrimp. They are characterized by having two pairs of feelers (antennae) in front of the mouth, by breathing by gills attached to some of the legs, and by a ladder-like nervous system. As they have a hard, unyielding external skeleton, they can increase in size only by shedding the external skin at irregular intervals. Several thousand species are known.

Cuttlefish (*Cephalopoda*). A mollusc in which there are ten arms around the mouth. The internal shell is calcified and is used as a supply of lime for cage birds. They have also an ink bag, the secretion of which furnishes the pigment sepia. Cuttlefish are an important article of food in southern Europe.

Deer (*Cervidae*). Animals of graceful form, combining much compactness and strength with slenderness of limb and fleetness. They use their horns as weapons of defense and offense; but in general they trust to flight for their safety. They have a long neck, a small head, which they carry high, large ears and large, full eyes. Many have scent glands, usually beneath the eyes, which serve as sexual attractions. Deer are distinguished from all other ruminants by their branching horns (antlers), which in most species exist in the male only; they are solid, fall off annually, and are renewed with increase of size and number of branches, according to the kind, until the animal has reached old age.

Deer are found in almost all parts of the globe except Australia and the south of Africa, their place in the latter region being supplied by antelopes. The greater number inhabit the warmer temperate countries, and they are chiefly found in wide plains and hills of moderate height. The flesh (venison) of most kinds of deer is highly esteemed for the table, and they have long been regarded as among the noblest objects of the chase. Only one species, the reindeer, can be said to have been fully domesticated.

Dodo (*Didídae*). Extinct pigeons of large size. These birds were formerly quite abundant on the island of Mauritius, but after 1681 there are no records of them. The size, judging from skeletal remains and a few records, was larger than that of our turkeys. The dodo had white underparts and tail and a darker back. The bill was large and ended in a curved hook.

Dog (*Canis* spp.). An animal well known for its attachment to mankind, and remarkable for the almost infinite varieties, as to size, form, color and quality of the hair, which domestication has brought about. It belongs to the order of carnivorous mammals. The genus *Canis* includes, besides the dog, the jackal and the wolf. It is a question of considerable interest as to what was the parent stock of the dog. Some are of the opinion that the breed is derived from the wolf; others that it is a domesticated jackal; all agree that no trace of it is to be found in a primitive state of nature. That there are wild dogs, we know. The dhole of India and the dingo of Australia are examples which exist in a state of complete independence, and throw no light upon the question. The dog will live on cooked vegetable matter, but prefers animal food. In drinking, it laps with the tongue. It never perspires, but the nose is naked and moist; when hot, the tongue hangs out of the mouth. The female goes with young sixty-three days, and usually has about six or eight at a litter. The young are blind at birth, and do not acquire their sight until the tenth day. The dog attains its full growth at the expiration of the second year, is old at fifteen, and seldom lives beyond twenty years.

Dolphin (*Delphinidae*). Whale-like animals which inhabit all seas. Dolphins swim in schools and have the habit of leaping far out of the water.

Dragon Fly (*Odonata*). An insect with a very long body, and long, slender, lace-like wings. It is a ferocious looking creature, but can do no harm. The eggs are laid in the water, where the young hatch and live. After a long period of time the larva crawls up the stem of some aquatic plant and transforms into the adult dragon fly. The adults are of value in destroying mosquitos.

Duck (*Anatidae*). A group of swimming birds. Most of the species are migratory and some, like the mallard and the shoveler duck, are found in both the Old and the New World. Among the interesting forms are the eiders, well-known from their soft down. They are found in cold regions. The Labrador duck was formerly very abundant, but is now probably extinct. Specimens of it in museums are far rarer than those of the great auk. The wood duck is possibly the most beautiful species.

Duckbill (*Ornithorhynchus anatinus*). An Australian mammal living in streams and feeding, like a duck, on the organic matter contained in the ooze at the bottom. In accordance with these habits, the toothless jaws are lengthened into a duck-like beak, and the feet are webbed. The duckbill does not bring forth its young alive as do the other mammals, but lays eggs. It averages about a foot in length.

Eagle (*Accipitres*). A bird belonging to the same family as the falcons and the hawks. They are found in all parts of the globe. The size varies according to the species, but all attain imposing dimensions. The bald eagle, the emblem of our country, is so called from the white head feathers. The golden eagle measures about three feet nine inches in height, and the spread of its wings is nearly ten feet. The eagle soars at great heights, and its sense of vision is very acute. It builds its nests in the clefts of inaccessible rocks, and lays generally two or three eggs; the period of incubation is thirty days. Besides the bald eagle and the golden eagle, there are other species, such as the whitetailed eagle, the tawny eagle, the booted eagle and numerous smaller species in tropical regions.

Earthworm (*Lumbricidae*). A group of burrowing worms, found in the earth in almost all parts of the world. They are without eyes or appendages. They live on the organic matter in the soil, and to obtain this they swallow the earth through which they mine, and cast the refuse on the surface. This makes them of great value to the agriculturist, as they work over and loosen the soil. In the winter they burrow down beneath the frost, and the large numbers frequently seen after a storm is not due to their having descended with the rain, but to their having been drowned out of their holes.

Echinoderms. Sea animals in which the body is usually arranged in parts of five around a central disk. The group is world wide in distribution, and contains the starfishes, sea urchins, sea cucumbers, sand dollars and sea lilies. The group as a whole is characterized by having small structures known as "tube feet," by which they move and obtain food. The feet are controlled by water pressure, and act by suction. There are hundreds of these feet extending around the animals. Sea urchins are almost spherical, having spines extending from almost all parts of the body. Movement is due to these spines and the tube feet. Sea cucumbers are found buried among the ooze at the bottom of the sea. They are soft bodied, with very rudimentary skeletal parts. When violently irritated they have the curious habit of throwing out the intestine and growing a new one. Sea lilies are among the most beautiful sea animals. They remain attached, throughout their adult life, by a stalk.

Edentates. A group of mammals in which the teeth are not always lacking, as the name would imply, but in which they are imperfectly developed. The group is largely American and includes the armadillos, sloths and anteaters.

Eel (*Anguilla* spp.). Fishes of very elongate snake-like form, living in the sea. There are several species belonging in very different groups. They should not be confused with the lamprey eels (see Lamprey), which are not true fish. The lamprey eels ascend the rivers in spring to deposit their eggs, while the true eels descend from the rivers in the fall to the sea for the purposes of reproduction. The breeding place is near the West Indies. The eels from Europe as well as from America collect here and sink to the bottom, where the spawning takes place. The young eels, when they are large enough, start back to fresh water; and it is reported that they find the same river from which their parents came.

Eider (*Somateria* spp.). Ducks of both the European and American continents. They are northern birds, going south only in winter. Most species live wholly in the water, and go to land only at the breeding season.

Elephant (*Elephas* spp.). A group of mammals, the only living representatives of the animals with a trunk or proboscis (*Proboscidea*). They are confined to the tropical regions of the Old World, in the forests of which they live in herds. Only two existing species are known, the Asiatic elephant and the African elephant. In both species the two upper incisors, or front teeth, are enormously developed, constituting long tusks. The lower incisors are absent, and there are no other teeth in the jaws except the large molars, or grinders, of which two are usually in use at one time on each side of each jaw. The molars are very large and are composed of a number of transverse plates of enamel, united by dentine. The nose is prolonged into a cylindrical trunk, movable in every direction, highly sensitive, and ending in a finger-like lobe. The nostrils are placed at the extremity of this trunk. The feet are furnished with five toes, but these are only indicated externally by the divisions of the hoof; and the sole of the foot is formed of a thick pad of skin.

The Indian elephant is the only species which is domesticated; and, as it will scarcely ever breed in captivity, the demand for it is supplied entirely by the capture of adult wild individuals. The Indian elephant has a concave forehead and small ears, while the African elephant has a convex forehead, and large ears. The African elephant is chiefly hunted for the sake of its ivory, and there is reason to believe that the pursuit will ultimately end in its extinction.

Elephants are vegetable feeders, living almost entirely on the foliage of shrubs and trees, which they strip off by means of the prehensile trunk. As the tusks prevent the animal from drinking in the ordinary manner, the water is sucked up by the trunk, which is then inserted in the mouth, into which it empties its contents. Many species of fossil elephants are known, the most familiar of which are the mammoth and the mastodons.

Elk. See Moose.

Emu (*Dromaeus* spp.). Peculiar Australian birds, similar in habits and appearance to the cassowaries and rheas. They are strong runners and depend upon their legs to escape danger. They are native to the level plains of Australia where they collect in small groups, although they are often seen alone.

Ermine (*Putorius erminea*). A member of the weasel group, native to Asia and America. The belly is white, and the back is dark brown. Some of the northern varieties have the power of changing color, becoming white in winter.

Falcon (*Falconidae*). The falcons proper, for strength, symmetry and powers of flight, are the most perfectly developed of the feathered race. They are distinguished by having the beak curved from the base, hooked at the point, the upper mandible with a notch or tooth on its cutting edge on either side, wings long and powerful, the second feather rather the longest, legs short and strong. Most prominent of the falcons are the peregrine falcon and the gyrfalcon. These were the principal birds used in falconry during the Middle Ages, not only in Europe but through the East. At one time the sport was allowed only to the nobility. Falcons were carefully trained, and at a hawking party the birds were

loosed and they immediately set upon any other game that might be in sight. The sport was in watching the falcon getting the better of other birds, sometimes many times the size of the falcon.

Finch (*Fringillidae*). Small birds with stout bills. The sexes may or may not be diffcrently colored. The finches include such forms as the linnets, sparrows, yellow-hammer and many others of like habits and structure. They are to be found in all types of places, especially in forests and open meadows. Seeds, insects and fruits form the greater part of their food.

Firefly (*Lampyridae*). Nocturnal beetles with light-producing organs on the lower side of the abdomen. It is thought by some that this lighting power is used by fireflies to attract mates. The nature of the light is interesting, as apparently little or no heat is produced. It is probably due to an excretion.

Fishes (*Pisces*). One of the lowest classes of vertebrate or backboned animals. They are adapted for an aquatic life, their shape being such as to permit easy and rapid progress through the water. They breathe by gills placed on the walls of slits in the sides of the neck, and their appendages (fins) are such as to make efficient paddles. There are usually one or more fins in the middle line of the back and one or two in a corresponding position beneath the tail (anal fins); while the tip of the tail is terminated by a caudal fin, the chief organ of swimming. The caudal fin presents three different types. In the diphycercal fin the backbone is straight at the tip, and the lobes of the caudal fin are equally disposed on its two sides. In the heterocercal tail the backbone is turned upward at the tip, this making one lobe, while a smaller second lobe is developed on its under side. This is the type of tail in the sharks. The homocercal tail has the same bent backbone as the last, but the two lobes are equal. Most fishes have the latter type. All of the fins are supported by a skeleton of rays, either horny or spinous in character.

There are several great groups of fishes, distinguished by the presence of a cartilage or a bony skeleton, by having the gill slits free or under a gill cover, by characters of the skull, presence or absence or air bladder, and by peculiarities of the digestive tract and nervous system.

Flatfish (*Pleuronectidae*). A group of fishes, including the halibut and the sole, in which the much flattened body represents an extreme modification. Both of the eyes are found on the same side of the head, and in the fish living on the bottom of the ocean, the eyes are uppermost. The belly of the flat fish is usually white, while the back often possesses remarkable powers of color change enabling the fish to conform to the color of its surroundings.

Flea (*Siphonaptera*). A group of wingless insects, mostly parasites on other animals. They have a hard skin, covered with spines so arranged that they can easily work themselves through the hair, legs admirably adapted for jumping, and the mouth-parts fitted for piercing and sucking. The fleas breed in the cracks in a floor or in some similar place where there is dirt, and when they are mature they attack animals. The irritation and annoyance of their bites are sufficient to make them a nuisance, and now it is known that they are an important agency in the transmission of certain diseases. Bubonic plague is communicated to man by flea bites.

Fly (*Diptera*). A term applied to various insects of different groups, but strictly belonging to the two-winged insects. Besides the number of wings, the group is distinguished by having a metamorphosis, and by its sucking mouthparts. There are from 30,000 to 40,000 species of flies known. Some species are closely connected with man, and of these the common house fly is especially noticeable. This lays its eggs in manure or other refuse, these hatching out, passing through all their stages and emerging as perfect insects in a few days. Their uncleanly habits make the house flies most efficient agents in the carriage of different diseases, especially typhoid fever and others which attack the digestive tract. House flies are thus not merely a nuisance to be deplored but are a positive danger to mankind. Among other flies are the carrion flies, black flies, the gnats and the mosquitos, all troublesome to man. Some species attack various plants.

Flycatcher (*Muscicapidae*). Small birds with short, broad bills and long tails. They are commonly found in Africa, India and Australia, but occasionally migrate to Europe. Flycatchers are so called because of their food, which consists mainly of insects caught on the wing. The group as a whole is found in forested regions.

Flying Fish. A name common to various fishes which have the power of sustaining themselves for some time in the air by means of their long front fins, which act as wings. While not restricted to any one group of fishes, the name usually refers to the genus *Exocoetus*, which are perhaps the best known examples, and which can maintain their flight for as much as 200 yards. The reason why flying fishes leave the water probably is their desire to escape from larger sea animals which feed on them.

Fox (*Canis* spp.). Carnivorous animals, of which there are several species, belonging to the same family as the dog. The fox is characterized by its sharp muzzle, by its long bushy tail and by its cunning, which has passed into a proverb. The pupil of the eye is elongated and not circular as in the dog, and the ears are triangular and pointed. A very powerful scent is emitted from glands near the root of the tail; this odor is so fetid that even other animals avoid its locality.

The common fox is an inhabitant of most parts of Europe and America, and extends also into northern Asia. Its senses are extremely acute. It usually remains concealed during the day in a burrow, and ventures abroad chiefly at night, in search of food. Birds, rabbits or hares constitute its usual prey, but, when pressed by necessity, it will have recourse to other food, and it likes certain kinds of fruit, such as grapes. It is destructive to poultry. Though slightly made, the fox has great muscular vigor, and bites with much severity. Even when taken at a very early age, it is never properly domesticated. Adults, when placed in confinement, show great ferocity and soon die.

Numerous other species of foxes exist of which the most important are the arctic, or blue fox, and the American, or red fox. The arctic fox is remarkable for changing its color with the season, being brown or bluish in summer, and white in winter; the soles of its feet are hairy. The red fox, found throughout North America, is very variable in color and marking, and varieties of it are known by different names. The skins of all the species are valuable.

Frog (*Rana* spp.). The common name for many genera of amphibians. All are characterized by smooth skin and webbed hind feet. Frogs are quite widely distributed over the world. The adults lay their eggs in long strings in the water, and from them are hatched out larvae (the tadpoles). These are fish-like in having a broad, swimming tail and gills on the sides of the neck. The tadpoles feed upon small aquatic plants which they scrape from sticks and stones with their horny jaws. As they increase in size, the legs grow out and the tail is absorbed. In the growth of the legs, the anterior pair is first formed, but as this pair is at first under the skin, it is usually thought that the hind pair is first formed. With the growth of legs and the loss of tail the gills disappear and the lungs come into use, but most species always remain in close proximity to water throughout their lives. The adults live on animal food—such as insects, molluscs and small fishes—and do not hesitate to eat their own species. They do much good in keeping down certain species of insects; moreover, their hind legs furnish an article of diet. Frogs are also an important animal for physiological investigations, because of the great vitality of their tissues.

Fruit Fly (*Drosophilidae*). Very small insects commonly found around bananas and other fruit in which their larvae develop. Much of what we know today concerning heredity has been learned from a study of fruit flies. The Mediterranean fruit fly is a destructive pest, especially on citrus fruits.

Garfish. See Bony Pike.

Gavial. See Crocodile.

Gazelle (*Gazella* spp.). An animal belonging to the antelope family, of very graceful shape, and rather smaller than the chamois. The color is fawn or dun on the back, separated from the white belly by a brown or blackish band. The horns, stronger in the male than in the female, are in the shape of a lyre. It inhabits the large plains and the Saharan region of northern Africa, as well as Arabia and Syria, living in herds. Gazelles are among the swiftest animals known.

Giraffe (*Giraffidae*). The tallest mammal, often called the "camelopard," because the neck resembles that of a camel, while the skin is spotted like a leopard. It inhabits various parts of Africa. The height ranges from fifteen to twenty feet, the greater part of which is the enormous length of the neck. Nevertheless, the giraffe has only the usual number of seven neck bones as in the whole class of mammals. It has an unusually long cylindrical tongue, which is prehensile, and which is used for stripping the leaves off the trees on which it feeds.

Goat (*Bovidae*). A group of animals closely allied to the sheep, although the common domestic goat and sheep are of widely different appearance.

The uses of the goat are numerous. The flesh, especially that of the kid, or young goat, is much used as food, though rather poor in quality. The milk is very rich and nutritious, more easy of digestion than that of the cow, and is often useful to consumptive patients. Some goats yield as much as four quarts of milk daily, although the average quantity is more nearly two. The skin is dressed as leather for many uses, particularly for gloves and the finer kinds of shoes. The horns are used for making knife-handles, and the fat is used in making candles.

Goats are found in wild mountainous countries where they scramble among the high rocks. The Rocky Mountain goat is an animal of the antelope family. Its size is about that of an ordinary sheep, and its general appearance is about that of a sheep of the merino breed with long straight hair. See Sheep.

Goose (*Anatidae*). Web-footed birds, having the bill not longer than the head, the upper mandible slightly hooked at the tip; the legs farther forward than in ducks, and so better adapted for walking; the neck of moderate length, and having sixteen vertebrae, a character which distinguishes them from swans. In general, geese spend much of their time on land, and feed on grass and other herbage, berries, seeds and various kinds of vegetable food. Although large birds and of bulky form, they have great powers of flight. They strike with their wings in fighting, and there is a hard callous knob or tubercle at the bend of the wing, which in some species becomes a spur. The domestic goose is regarded as deriving its origin from the common wild goose, but all the species seem capable of domestication. The graylag goose is almost three feet in length from the tip of the bill to the extremity of the short tail. Its extent of wing is about five feet. The weight of the largest birds is about ten pounds.

Gopher (*Sciuridae*). Squirrel-like animals which live in burrows on the open plains. Their principal diet is seeds and grain. Gophers burrow, and their onslaught on seeds and roots make them a trouble-some pest in some localities.

Gorilla (*Gorilla gorilla*). The largest of the manlike apes from tropical west Africa. They reach a height of four feet eight inches and the arms are shorter in relation to the body than in any other ape. Gorillas are very strong, but usually they retreat before man. They can climb, but are far less arboreal than their relatives, the chimpanzee.

Grackle. The common name for certain birds of the family *Icteridae*, common in the United States. The most familiar representative is the rusty grackle, sometimes called "blackbird." The purple grackle is noted for the lustrous nature of its plumage.

Grebe (*Podicipedidae*). Water birds found on all continents, inhabitants of slow streams and ponds. When disturbed, grebes usually dive below the surface, where they can stay for some time. They are good flyers, however, but have some difficulty in leaving the surface of the water because of the small size of their wings. Their food consists mainly of small fish, frogs and insects.

Guinea Fowl (*Numidinae*). Game birds native to Africa and Asia. Most of the species of guinea fowls inhabit grassy areas, through which they can run easily. They are also raised as domesticated fowls. They are mainly vegetarian, digging and scratching for seeds and roots.

Guinea Pig or Cavy (*Cavia* spp.). A small rodent native to South America. It has been introduced into Europe and America, where it is domesticated as a pet. It possesses a very low degree of intelligence. In its natural home it is gregarious, and is usually found living on dry lands covered with low brushwood. The color is variegated. The tail is rudimentary. It is extremely prolific, and begins to breed at the age of ten months, producing several broods in a year; each litter usually consists of about eight. The popular name is very inappropriate; the animal does not come from Guinea, nor is it a pig.

Gull (*Larinae*). Large web-footed birds, common about large bodies of water in the Northern Hemisphere. Their colors are usually white below, with the upper parts varying from a light gray to a black. All are much alike in their habits, noisy and quarrelsome, searching the water for any possible scrap of food, and often following ships for days. They breed on uninhabited islands. The closely allied terns are usually smaller, and have a forked instead of a square or even a pointed tail. Both are strong fliers but the terns are the more graceful.

Haddock (*Gadus aeglefinus*). One of the most important of the food fishes, closely related to the cod, but distinguished by the notched tail and a white line along the side. In habits the two are much alike, both being greedy and both eating anything edible, especially clams; this habit is so noticeable that the Germans have given the haddock the name "shell-fish."

Halibut (*Hippoglossus vulgaris*). A member of the group of flatfishes, remarkable in having the eyes on the same side of the head and in swimming, not in a vertical position, like other fishes, but on the side, with the eyes uppermost. The very young flatfishes are normal, but when less than half an inch long they turn on the side. At the same time the eye begins its migration, which ends by both eyes being on the same side, the twisting even distorting the bones of the skull. The average weight of the halibut is about 120 pounds; the largest known weighed 720 pounds. The flesh is white and most excellent.

Hare (*Lepus* spp.). Rodent animals which are very common in most parts of the world. They feed mostly on herbage, although grain, roots and bark are sometimes eaten. The common American cottontail (*L. sylvaticus*) is a familiar animal all over the country. In the North, the varying hare (*L. americanus*) is found. This is a brownish color in summer, the color turning to a snow white in the winter. In the West and Southwest, the jack rabbits (*L. texianus*) are found. These hide in the bushes by day and feed on herbage by night. Hares breed very rapidly. They were imported into Australia recently where, on account of their vast numbers, they have become a real menace.

Harvest Man (*Phalangiidae*). A curious group, closely related to the spiders, and very commonly called "daddy-long-legs." They differ from the spiders in having very long legs and small, often hard, bodies. Unlike many of the spiders, harvest men cannot spin webs. A pair of eyes are present on an elevated turret on the back of the animal. Harvest men are abundant in fields and forests in all parts of the world from May to October. Eggs are laid in the fall and hatch the following spring. A few species sleep through the winter, but the majority of the adults die each fall after the breeding season. Their food consists mainly of small insects and other animals.

Hawk (*Falconidae*). All daytime birds of prey which are not eagles or vultures. Hawks are common in all parts of the world. They are almost wholly

29 Lion.

carnivorous, and rarely take food that has not been recently killed. The plumage is usually brown or white, although gray is not uncommon. The nests are built in trees and on rocky cliffs; occasional ground nests are found. Hawks are both beneficial and injurious. The common chicken hawk (*Accipiter velox*) is a menace to poultry keepers. It is small, measuring only eleven to thirteen inches in length. The back is of a grayish color with bars of brown. The under parts are whitish, while the feet are yellow. The marsh hawk (*Circus cyaneus*), on the other hand, is a highly beneficial animal, as it kills such pests as rats, mice and grasshoppers. It never feeds on birds.

Hedgehog (*Erinaceus* spp.). These spiny animals, native to the Old World, can roll themselves up into a ball and extend the spines outward. Hedgehogs measure from ten to twelve inches in length. The legs are short, and the snout is long. The spines are usually about an inch in length. The food of hedgehogs consists mainly of small reptiles, birds and mammals. They are nocturnal in habits, hiding during the day in logs and stumps. During the winter, hedgehogs hibernate in protected places. The meat is sometimes eaten in Europe, but the practice is uncommon.

Heron (*Ardeidae*). A group of long-legged birds which are usually found near bodies of water. They are commonly seen standing on one leg in shallow water, although they fly when disturbed. Herons nest high in trees in structures built of grass and twigs.

Herring (*Clupea* spp.). Small soft-finned fishes, spread over the whole North Atlantic, of great economic importance. They occur in large schools, swimming through the sea with open mouths, scooping up the minute life for food. Immense numbers are taken both here and abroad, the annual catch for Europe and America being estimated at 1,500,000,000 pounds. The young are also taken in vast quantities and are preserved as American sardines. In America, most of the adults are smoked and dried.

Hippopotamus (*Hippopotamus* spp.). An animal related to the pigs, hogs and peccaries, and belonging to the order *Ungulata*. There is only one living species, *Hippopotamus amphibius* of Africa. It is enormously bulky and unwieldly, attaining a height of five feet and a length of twelve feet. The feet are massive, and are terminated by four-hoofed toes; the skin is very thick. The hippopotamus feeds upon vegetable substances, such as grasses and shrubs; it dives and swims with great facility.

Hookworm (*Necator americanus*). A small worm found commonly in the soil of warm countries. As a parasite it bores through the human skin, and makes its way finally into the intestine. There it causes severe bleeding which results in marked weakness. The lungs are also subject to attack, and the victims often contract tuberculosis. It is estimated that 2,000,000 people are affected by this parasite.

Horse (*Equus* spp.). An ungulate, or hoofed mammal. The horse proper is characterized by the tail with long hairs from its base; the long and flowing mane; a bare callosity on the inner surface of the hind, as well as of the fore legs; and by the head and ears being smaller and the limbs longer than in the ass and other related species. The native country of the horse seems to have been central Asia. It became domesticated in Egypt at an early date. It is mentioned throughout the Bible. The Greeks and the Romans had some covering to insure their horses' hoofs against injury. In the ninth century, horses were shod only in time of frost. Shoeing was introduced into England by William I, 1066.

It is believed that the original breed of horses is extinct, and that the half-wild herds existing in many places have descended from animals once in captivity. Thus, when the horse was first introduced by the Spaniards in 1537, at Buenos Aires, there were no wild horses in America. But individuals escaping ran wild, and, by 1580, their descendants had spread over the continent as far as the Straits of Magellan. More fossil horses have been found in the New than in the Old World. The horse may have descended from a striped ancestor, stripes sometimes still remaining, especially in duns and mouseduns. Its age is ascertained by examining: first, which teeth are developed, and second, to what extent they have been worn away by use.

Like other domestic animals the horse has run into various breeds. The most celebrated is the Arab horse. Great attention is given in America to the breeding of race horses.

Humming Bird (*Trochilidae*). One of the smallest of birds, of great delicacy of body and wonderfully brilliant plumage, wholly restricted to the American continents. Only three or four species are found in the United States. The common name is due to the humming noise made by the wings when the bird flies. The beak is long and curved, allowing the animal to reach into flowers and get small insects, upon which it lives. Aside from their beauty there is little else attractive about them. They have little intellect and are very quarrelsome.

Hyena (*Hyaenidae*). Carnivorous, dog-like animals which inhabit the semiarid portions of Africa and Asia. These animals are covered with coarse, bristly hair, short over the greater portion of the body, but forming a mane along the ridge of the neck. The hind legs are shorter than the fore, giving the body a slope from the withers to the haunches. In size they are somewhat larger than a shepherd's dog. The cheek muscles are greatly developed, and the large grinding teeth have great conical crowns, giving to them the power of smashing the thigh-bones of animals the size of a horse. As carrion feeders they are useful scavengers. All the species are nocturnal in their habits.

Hyrax (*Hyrax* spp.). The hyrax, or cony, is a small African ungulate which resembles a guinea pig. It has been long known as a wise animal from the fact that it is difficult to trap.

Ichneumon (*Ichneumonidae*). Parasitic insects, allied to the wasps and bees. They lay their eggs in the caterpillars of moths and butterflies. The abdomen is long and slender, and has at the end a long extension by which holes are bored and eggs deposited.

Iguana (*Iguanidae*). Tropical lizards in which the body and tail are laterally compressed. A number of soft spines extend from the head to the tip of the tail, and give a crested appearance. They live mainly in trees.

Insects (*Hexapoda*). The largest group in the animal kingdom, found in all types of places. Although they are largely terrestrial, some have taken to the water. Some insects have become parasitic on other animals. The body of an insect is divided into three general regions: (1) head, (2) thorax and (3) abdomen. The head contains the mouthparts which are differently constructed in different insects. Some insects, as the beetles, have the mouthparts constructed for biting; others, as the mosquitos, possess a sucking apparatus. Insects have three pairs of thoracic legs, and one or two pairs of outgrowths from the top of the back to form wings. The fly group (*Diptera*) has only one pair of wings, but most of the other groups of insects are provided with two pairs, although some of the simpler forms (*Thysanura*) are without wings. Insects breathe by means of small tubes which extend throughout the body and take air to all parts of the insect. The sense organs of insects are usually in the head. The large eyes are composed of hundreds of parts, each part complete in itself. There is usually a pair of feelers, or antennae, which act as tactile organs.

Most of the insects have several stages in their development. After hatching from the egg the animal is known as a larva. This is the period when insects are most destructive, as much of the eating is done at this time. After a time the larva transforms into a pupa, which is a quiet stage in which reorganization of the body takes place. The pupa transforms into the adult insect, or imago. Insects show a great variety of forms. The fish moths (*Thysanura*), often seen in damp cellars, have an almost white body and no wings. The locusts, grasshoppers, crickets and cockroaches (*Orthoptera*) have typically two pairs of wings, but may be wingless. The beetles (*Coleoptera*) have the first pair of wings modified into hard covers which protect the second pair. The bees, ants and wasps (*Hymenoptera*) are famous for the social life which exists in their colonies. The true bugs (*Hemiptera*) may be recognized by the fact that the wings are folded across the backs and by the sucking mouthparts. The dragon flies (*Odonata*) are ferocious looking creatures with two pairs of long membranous wings which are held outright, even when not flying. Butterflies and moths (*Lepidoptera*) are familiar everywhere. The fleas (*Siphonaptera*) are parasitic, wingless insects which are often present among the hairs on various mammals. The flies and mosquitos (*Diptera*) have only one pair of wings.

Jaguar (*Felis onca*). Carnivorous mammal of the cat family, somewhat larger than a leopard, and with black streaks and spots. The jaguar is one of the most formidable beasts of prey found on the American continent. It is typically South American, but is native as far north as Mexico. The banks of rivers are its favorite haunts. Here it preys on such animals as the water hog; it is also said to catch fish. The jaguar is a noisy animal, roaming abroad at night, especially before the approach of bad weather.

Jay (*Garrulinae*). Several kinds of jays are found in America. The common blue jay, which ranges over much of our country, utters a very harsh note and goes through many contortions. Most of the jays are crested, the coloration indicating the species.

Jellyfish (*Scyphozoa*). A common name for numbers of marine animals belonging to the group called by naturalists *Coelenterates* (which see). All are alike in having a more or less bell or umbrella shaped body, with a proboscis hanging down in the place of the handle of the umbrella or the tongue of the bell. The mouth is at the end of the handle and leads into a stomach which divides and sends out branches, like the ribs of the umbrella, to the margin. The common name is given it because of its gelatinous consistency. Most of the species start in life as buds from attached animals, which later separate and henceforth lead a free existence, swimming by opening and closing the bell. The jellyfish are the sexual animals, producing the eggs from which the fixed stages arise. None of the jellyfish has any economic value. They have nettling organs which are used for defense and to kill their prey. In some they are strong enough to cause severe irritation to man. A general name for the group is *Medusae*, while the fixed stages are called "polyps."

Kangaroo (*Macropus* spp.). A pouch-bearing (marsupial) mammal. Kangaroos are the most highly developed members of the order, *Marsupialia*, and are found in Australia, taking the place of deer and cattle. The family comprises over fifty species, and of these the great kangaroo may be taken as a type. This species was formerly plentiful over the plains, but it is now retiring before the colonists.

The forelimbs of the kangaroo are small; the hind limbs very large and thick; the head small, with rather long ears, and a long, dusky-brown muzzle; the body long, with the fur shortish but thick, and of a gray-brown tint. In height it is as tall as, or taller than, a man. The female carries her young in a pouch on the underside of the belly. When moving quickly, the hind limbs alone are brought into action, and by means of these the animal bounds along in great leaps of from ten to fifteen feet, the body being carried in a nearly horizontal position, and the tail extended to balance it. The fore-limbs are chiefly used in handling, and with these the females lift their young, and place them in the pouch. The kangaroos are vegetable feeders.

Killdeer (*Aegialitis vocifera*). A common bird in the fields, plains and pastures of central North America. The neck is marked by two black bands, which are in striking contrast to the white body. The killdeer has the interesting habit of pretending to have a broken wing when one comes near its nest, which is built on the ground. If the bird is followed, it leads the intruder away from the nest and takes to the air.

Kingbird (*Tyranus pipiri*). The kingbird is dark gray with white underparts. It ranges over the greater portion of temperate North America. It is commonly found in trees, from which it ventures to catch its prey. Its note is rather harsh and shrill.

Kingfisher (*Alcedinidae*). Birds of various species and colors, generally found near quiet streams. The shape of the kingfisher is somewhat awkward, the head appearing large, due partly to a crest. Its food is mainly small fish which the bird gets by diving. Insects are sometimes eaten. The nests are usually built in tree trunks or in the banks of streams, after the fashion of the cliff swallow.

Lac Insect. See Cochineal Bug.

Ladybird (*Coccinellidae*). Ladybirds, or ladybird beetles, are well-known insects frequently seen on flowers. The body is often yellow with black spots. These beetles are almost all predacious (feeding on other animals), although some are known to eat plants.

Lamprey (*Cyclostomata*). Eel-shaped animals, mostly living in the sea, but going to fresh water to lay their eggs. The large sea lamprey is nearly three feet long. It has no lower jaw, but its mouth is permanently open and is lined with horny teeth by which the animal fastens itself to other fishes, on the blood and mucus of which it lives. There is a single nostril and seven gill openings on the side of the neck.

Allied to the lampreys are the hagfishes, which become true parasites, entering the body of a fish through the gills and completely devouring the flesh in a single night. The hagfishes are not common on our East coast; they are more abundant in Europe and in California.

Lark (*Alaudidae*). The common name for birds of the genera *Alauda* and *Sturnella*. The skylark of Europe, the most harmonious of this musical group, begins its song early in the spring, continues it during the whole summer, and is one of the few birds which sings on the wing. When it first rises from the earth, its notes are feeble and interrupted; as it ascends, however, the song gradually swells to a full tone, and long after the bird is lost to the sight, the notes continue to charm the ear with their melody. The lark mounts almost straight up, but descends in a glide. If there is danger, however, it falls suddenly. The meadow lark of North America, about ten inches long, somewhat resembles the skylark in its habits, but the song is not so sweet.

Leech (*Hirudinia*). Leeches are a group of flattened worms found almost entirely in fresh water, though in Asia there are species which live on the land or in trees. At the anterior end is a sucker, and there is a second at the hinder end. The anterior sucker surrounds the mouth and this, in some species has radiating from it three jaws, each like half of a buzz saw. With these they cut the skin of higher animals, sucking their blood through the wound. Half a century ago leeches were extensively used by physicians in the attempt to relieve certain diseases, but it has since been found out that the human system needs strengthening, not weakening, and the use of leeches has ceased.

Lemming (*Myodes* spp.). Rat-like animals found in northern Europe and Asia. They are famous for their great migrations which occur periodically every eight to ten years. During these times the number of individuals is enormous, and the lemmings start for the coast, being stopped only by the waters of the ocean. In their migrations they destroy much in the way of grain and other crops.

Lemur (*Lemurinae*). Monkey-like animals which are native to the island of Madagascar. Little is known of the habits of these animals. They are mostly arboreal and nocturnal. The tail is long in proportion to the body. The eyes are very large and present a staring appearance. Lemurs are both vegetable and animal feeders.

Leopard (*Felis pardus*). A cat-like animal which differs from the panther in having small spots thickly set, while the panther's spots are large and open. The species is a native both of Africa and Asia. The body of this fierce and rapacious animal is about four feet long. It can take surprising leaps, can swim and can ascend trees.

Lion (*Felis leo*). The largest and most majestic of

carnivorous quadrupeds. It is, when mature, of a nearly uniform tawny or yellowish color, paler on the under parts, the young alone exhibiting markings like those common in the *Felidae*; the male has, usually, a great shaggy and flowing mane, and the tail, which is long, terminates in a tuft of hair. The whole frame is extremely muscular, and the foreparts, in particular, are remarkably powerful. They give, together with the large head, bright eye and copious mane, a noble appearance to the animal, which, with its strength, has led to its being called "the king of beasts."

A lion of the largest size measures about eight feet from the nose to the tail, and the tail measures about four feet more. The lioness is smaller, has no mane, and is of a lighter color on the under parts. The strength of the lion is such that it can carry off a heifer as a cat carries a rat.

The lion is chiefly an inhabitant of Africa, although it is found also in Asia, particularly in certain parts of Arabia, Persia and India. It was anciently much more common in Asia, and was found in some parts of Europe (Macedonia and Thrace), according to Herodotus and other authors. The lion is an inhabitant of open plains in which the shelter of occasional bushes and thickets may be found. It is easily tamed, at least if taken young and if abundantly supplied with food.

Lizard (*Lacertilia*). A group of four-footed reptiles found in warmer climates, and especially abundant in the tropics. The body is covered with scales on both back and belly, while the head is covered with larger plates, called "scutes." This is important when the question arises regarding a few legless forms, which look like snakes, the presence of scales beneath, instead of broad scutes, showing at a glance their proper classification as lizards. Most of the lizards are insect eaters and thus do much good.

Only a single one, the Gila monster, is poisonous. Some of the larger tropical species are used as food. Some of the species have a great capacity for changing the color to correspond to the surroundings. This is most marked in the chameleons of Africa, and exists to a less extent in some of our American species which are popularly called by the same name. The change of color is due to the enlargement or contraction of small colored bodies in the skin. Among the interesting lizards are the horned toads of our Southwest; the glass snakes, footless lizards whose tails are very brittle and break off at slight provocation, and then grow again; the frilled lizard of the East, which has a wondrous collar which it raises when alarmed; and the geckoes of southern Europe, which crawl about on the ceilings of the rooms, uttering the cry which gives them their name.

Llama (*Camelidae*). An animal of Peru, allied to the camels in structure, and serving as the native beasts of burden, as does the camel in the Old World. It is about the size of the common deer, with a longer neck. It is capable of carrying a burden of 150 pounds.

Allied to the llama is the alpaca (which see), which is kept for the hair, used as a textile material and greatly in vogue in earlier days. When the hair was first sent to England, no one would touch it on account of the difficulty of working it satisfactorily. Titus Salt solved the problem, winning a fortune and the knighthood for his efforts.

Llamas and alpacas defend themselves by spitting and biting, and many a visitor to zoölogical gardens has received a missile from the mouth of one of these beasts. Llamas and alpacas are known only in a state of domestication; wild relatives are the vicuna and the guanaco of Peru. Possibly the domesticated forms have descended from these.

Lobster (*Homarus* spp.). The most important crustacean, one species occurring on our New England coast, another on the coast of northern Europe. The body is divided into two regions, the anterior bearing, besides the parts used in taking food, a pair of large pincers and four pairs of walking feet. At the front of the head are two pairs of feelers, which are sensory, and a pair of eyes on the ends of short stalks. Lobsters are fond of decaying fish, and are among the scavengers of the sea. They are caught in large traps, called "lobster pots," made of lath and baited with decaying fish. The number taken is enormous, but over-fishing has greatly reduced the numbers in the sea, so that almost everywhere laws have been passed to protect them. The annual catch on the New England coast is estimated at about thirty million pounds, the average weight of a lobster being between two and three pounds. In the Mediterranean the sea-crawfish (*Palinurus vulgaris*) is called a "lobster," and is greatly esteemed for table use.

Lungfish. Fish of several species which can withstand considerable drought. All are tropical in range. They live in rivers and ponds which dry up for part of the year. When the dry period comes the fish burrow into the damp earth and breathe by means of an air bladder which is similar to our lungs. When water again appears in the river, the fish leave the burrow, and the gills function as in other fish.

Lyre Bird (*Menuridae*). These birds get their name from the shape of the tail in the males, which looks very like a lyre, the outer tail feathers being curved outward at the ends. Most of the lyre birds are found in Australia and adjacent islands. They are forest dwellers and live on the ground. They dig their food, which consists of insects, centipedes and other burrowing forms.

Macaw. See Parrot.

Mackerel (*Scomber* spp.). An important food fish found in the North Atlantic and characterized by the slender shape, the series of little finlets on the tail and the deeply notched caudal or tail fin. It is taken both by hooks and by seines. Some are eaten in the fresh condition and some are salted. Formerly this fish was very abundant on the eastern coasts of the North Atlantic states, but recently it has been comparatively scarce, possibly the result of over-fishing. It goes in large schools.

Allied is the Spanish mackerel of our southern waters and the large horse mackerel, which is not very abundant with us, but which is more common in the Mediterranean, where it is called the "tunny." Large individuals may weigh over half a ton. Mackerel is used extensively as food, the chief fisheries being around Sicily.

Magpie (*Pica rustica*). A bird belonging to the crow family. There are several species, two of which belong to America. The common European magpie is about eighteen inches in length; the plumage is black and white, the black glossed with green and purple; the bill is stout, and the tail is very long. The magpies continue in pairs throughout the year and prey on a variety of food, chiefly animal. They are determined robbers of other birds' nests, destroying the eggs and young birds. In captivity they are celebrated for their crafty instincts and for their power of imitating words.

Mammals (*Mammalia*). One of the great groups of vertebrates, readily recognized by the hair (which occurs nowhere else), the warm blood, by the bringing forth of the young alive and the nourishing of them with milk secreted by the mother.

To the statement that they have living young and do not lay eggs it can reliably be said that the only exceptions are three small forms found in Australian regions. These form a group called "monotremes."

Next above them are the marsupials, in which the young are very immature when born. Therefore they are taken into a pouch on the ventral side of the mother, where they remain until able to shift for themselves. To this group belong our opossum; all of the others, including the kangaroos, wombat, sugar squirrel, and others belong to Australia and the adjacent islands.

Next are the insect eaters, or insectivores, including our moles and shrews; then come the rodents or gnawers (squirrels, rats, mice, porcupines, rabbits, beavers and others) in which the front teeth are fitted for gnawing.

The ungulates are the hoofed animals and are subdivided according as the number of toes are odd (horse, ass, tapir, rhinoceros) or even (cattle, sheep, deer, antelope, camel).

The elephants come next, at present restricted to Asia and Africa, but formerly spread over Europe and America in the species known as the mammoth and the allied mastodon.

Another group is the bats, the only flying mammals, which have a wing of skin supported on the extremely elongated fingers. All of our species feed on insects, but in South America there is one which sucks blood (vampire) and in Asia there are bats which eat fruit.

Whales form an additional group, wonderfully adapted for aquatic life, as are also the sirenians (manatee and dugong).

The carnivores are the flesh eaters, with teeth adapted to cutting flesh and cracking bones. Here are the bears, weasels, otters, mongooses, dogs, foxes, wolves, and the long line of cats. The seals and sea lions form an aberrant aquatic side branch.

Lastly come the primates, the group including the monkeys, apes and man.

Mammoth (*Elephas primigenius*). An extinct elephant-like animal, formerly having a range over much of Europe and Siberia. Unlike elephants of today, the mammoth had long, thick wool. The tusks grew to about fifteen feet in length and are known to have weighed 250 pounds.

Manatee (*Manatus latirostris*). A water mammal, known as the "sea cow," found on the coasts of Florida and tropical America. Manatees generally frequent the mouths of rivers and estuaries, and feed on algae and such seashore vegetation as they can reach at high tide. Their anterior limbs, or swimming paws are furnished with nails by means of which they drag themselves along the shore. They are large, awkward, whale-like animals, attaining a length of eight to ten feet as a rule, but sometimes growing to twenty feet. The skin is grayish-brown, sparsely covered with hairs. Their flesh is excellent, and they furnish a soft, clear oil which does not become rancid.

An ally, with similar habits, is the dugong of Australia.

Mandrill (*Cynocephalus mormon*). An African baboon, distinguished by a short tail. The cheeks are striped with red and blue, and the bridge of the nose is bright red. Mandrills associate in herds. They are ferocious animals, eating any kind of food.

Marsupials (*Marsupialia*). Primitive mammals in which the young are born in an imperfect condition and are carried in a pouch, or marsupium, on the body of the mother. The group as a whole is largely restricted to Australia and nearby islands, although the American opossum is a marsupial. The group includes the wallaby, kangaroo, opossum, phalanger and wombat.

Marten (*Mustela* spp.). Small carnivorous animals, widely distributed throughout North America and Europe. There are a number of species which are essentially alike, differing only in minor details. Most of the forms are dark brown with small ears. The most familiar American species is the pekan (*M. pennanti*), which may attain a length of over a yard. This genus also contains the sables and polecats, which are much alike in structure and appearance.

Mastodon (*Mastodon* spp.). An extinct elephant which formerly was native to both North and South America. It was the only elephant that extended its range into South America. Unlike most elephants it had tusks in both jaws.

Meadow Lark. See Lark.

Millipede (*Myriopoda*). Arthropod animals with an elongated body and two pairs of legs on each segment. They are sluggish animals and spend most of their time in protected spots, such as under stones and in other dark places. They feed on decaying organic matter and on the roots of plants. The body has many segments, the first of which bears two feelers. Stink glands are present on some species and provide a gas which is offensive.

Mocking Bird (*Mimidae*). A genus of the family of thrushes, exclusively American but ranging widely over North America. These birds are remarkable for their power of song.

The best known species is *Mimus polyglottus*, which has an unusually marvelous power of voice, and is able to imitate almost any species of animals, as well as noises produced artificially. Its own song is loud, full and exceedingly varied. In plumage it is decidedly somber, being of a general ashy-gray hue, paler beneath; its sweet and varied notes, and its faculty of imitation, render it a prime favorite.

Monkey (*Primates*). A common name for certain members of the mammalian group of primates, but no scientific definition is possible, for the term is used with very different meanings.

All of the American monkeys are true monkeys, but in the Old World there is no line between ape, baboon, gibbon, macaque and monkey. Most of the American species (the marmosets excepted) have one more molar tooth on each side of each jaw than does man, but the forms of the eastern continent are like man in that respect, just as they are in having nails, rather than claws, on at least some of the fingers and toes. Many of the New World species have prehensile tails, but this never occurs in the others, the tail exhibiting a tendency to be reduced, and at last disappears in the man-like apes. The American apes, moreover, have the nostrils widely separated and opening sidewise, while in the others they open in front and downward, as in man. Monkeys are extremely interesting because of their caricature of man. Some make most entertaining pets, while others are disagreeable in looks, temper and habits. The majority of them are vegetarians for most of their diet, but they are fond of eggs and young birds, as well as of insects. None stray far out of the tropics, and only one enters Europe, at Gibraltar.

Monotreme (*Monotremata*). The most primitive mammals known. They are found only in Australia, and are becoming extinct there. Unlike other mammals, the monotremes lay eggs as do birds, and hatch their young outside the body. After birth the young are transferred to a temporary pouch on the mother, into which milk ducts open. The most common representative of the group is the Australian duckbill, whose habits and appearance are suggestive of a duck. The feet are webbed, and a peculiar beak gives the appearance of a bird. In addition to this, it inhabits the water, scooping up fish with its beak in the fashion of a duck. See Duckbill.

Moose (*Alces machlis*). The largest member of the deer family. It is found in the North, where it roams through the forests. The antlers are massive structures, and are used by the animal in defending itself against enemies. The legs are longer and heavier than are those of the deer. See Deer.

Mosquito (*Culicidae*). A group of two-winged insects, related to the flies. The animals usually lay their eggs in water, and from them hatch out the larvae which, because of their motion in the water, are commonly called "wrigglers." When fully grown, the wrigglers come to the surface, the skin splits down the back, and the perfect insect emerges. As adults they live on blood, which they suck from punctures which they make by the proboscis. In order to stimulate the flow of blood they inject a little of their poisonous saliva into the wound. This causes the itching which was formerly thought to be the worst effect of their bite.

Within the past few years it has been found that mosquitos are the means of inoculating man with malaria, yellow fever and possibly other diseases. They get the germs from some one affected with the disease and, after a few days, are able to pass them along with the saliva. Thus, mosquitos of the genus *Anopheles*, which raise the hind end of the body when they bite, convey the germs of malaria. In the same way yellow fever is carried by mosquitos of the genus *Aedes*. This discovery has led to warfare against the mosquito and to preventing the attacks by means of screens. The best way of eradicating these pests is the emptying of all possible breeding places, and when that is not possible, covering the top of the water with kerosene.

Fortunately, not all species are able to spread these diseases. The commonest mosquitos, species of *Culex*, are not known to convey any disease.

Moth (*Lepidoptera*). The common name of certain insects belonging to the *Lepidoptera*. Like all

Lepidoptera they have scaly wings, the fore wings larger than the hind, and a sucking tube on the lower side of the head. They differ from the others of the group, the butterflies, in that the antennae or feelers on the front of the head never end in a club but, whether feathered or not, they taper to a point. When at rest they carry the wings horizontally instead of folded over the back, and with few exceptions they fly at night. Only a very few feed on anything except vegetable matter. The larvae of the clothes moth eat woolens, silk and other animal matter. In the larval or caterpillar state, many of the moths feed on and do great damage to plants. Among the worst pests in America are such recently imported species as the gypsy moth, the brown tail moth and the leopard moth. Our older forms, like the codling moth and the army worm, and the various measuring worms, are of far less importance. On the other hand, only a few are of any actual value; chief among them is the silkworm, which more than repays its depredations on the mulberry trees with the silk which it spins from glands near the mouth.

Mouse (*Mus* spp.). Mice are small mammals of the group of rodents, belonging to the same genus as the rats. Our common house mouse is an immigrant from Europe. Its habits are well known. There are some interesting varieties, among them the white or albino mice, which are kept as pets, since they are less apt to bite than are the wild stock. The Japanese dancing mice have the queer habit of turning around every few seconds. The field mice are a different species.

Mule. A hybrid between the horse and the ass, differing in size, strength and beauty, according to the predominance of its parental species, those between a male ass and a mare being far superior to the progeny of a she-ass with a horse. In mountainous countries mules are highly serviceable, no beast of burden being either so sure-footed, or so capable of enduring fatigue. In beauty of form they fall far short of that noble quadruped, the horse. The mule has a large, clumsy head, long erect ears, a short mane and a thin tail.

Musk Ox (*Ovibos* spp.). An animal closely related to the sheep but only remotely to the ox. Its body is covered with tufted hair, brownish in color and of great length. The hair about the neck and shoulders is so thick as to give the animal a humped appearance. The musk ox is active and agile. The horns, broad at the base and covering the forehead and crown, curve downward between the eye and the ear, and then upward and slightly backward. The horns of the female are smaller than those of the male. The ears are short, the head large and broad, the muzzle blunt. The average male will weigh about 400 pounds. The food consists of grass and lichens. The musk ox inhabits the arctic regions of America north of the sixtieth degree of latitude. The flesh is pleasant to the taste, though it smells strongly of musk, the odor of which is also diffused from the living animal.

Newt. See Amphibian.

Nightingale (*Passeres*). A genus of birds in which there are two species of similar plumage, inhabiting Europe and North America. One of these is a summer resident of the southern and eastern counties of England, arriving about the middle of April. The plumage of this delightful songster is of a dull hue, reddish brown on the upper surface and grayish white on the lower side. It is commonly found on hedgerows, from which it picks insects. The nest is composed of dry leaves, lined with grass, roots and hair. The eggs are four or five in number, and of a uniform olive-brown color, tinged with grayish-blue.

Octopus (*Cephalopoda*). Molluscs with a rounded body and a small head bearing a pair of well-developed eyes, the mouth surrounded by eight long arms, each arm bearing numbers of suckers by which the animals hold their prey. Inside the mouth is a pair of jaws, shaped much like those of a parrot. Most of the species are small, possibly averaging a weight of five pounds, but along the coast of Alaska some can spread nearly twenty-eight feet. The octopus is eaten extensively in the Mediterranean countries. The stories of large octopuses attacking man are very doubtful.

Opossum (*Didelphyidae*). A family of mammals, belonging to the order of pouch-bearers (*Marsupialia*) found in the Americas from the tropics to the middle temperate zones. One species is found from Florida north to the Hudson River, and west to the Missouri River.

They are rat-like in form, the largest species about the size of the common cat; they have a long tail, which is almost destitute of hair, and is very useful from its prehensile nature, enabling the animal not only to hang by it, but also to climb and descend trees. They are sly, and live chiefly in trees, lying up in the daytime, and at night roaming in search of their food. This consists of insects, small reptiles, birds' eggs and the like.

Orang-Utan (*Simia satyrus*). The Malay name (meaning "man-of-the-woods") for a large man-like ape found in Borneo and Sumatra. It never reaches a height much over four feet, but the arms of one specimen, four feet two inches tall, spread seven feet nine inches, and when erect the hands nearly touched the ground. The orang lives almost entirely in trees. It never jumps, but progresses through the forest by swinging itself from limb to limb. The skin is dark brown and the scanty hair is black. The young are more like the human being than is the adult. As the age increases the jaws protrude more and more and the disproportionate length of the arms increases.

Oriole (*Oriolidae*). A family of birds which inhabits the Old World. One species, the golden oriole, is a summer visitor in central Europe. The male of this species has a brilliant yellow body and black wings and tail. The female is of a greenish hue, streaked with dusky lines. It is about the size of the common thrush. The name oriole is also applied to several American birds, of which the Baltimore oriole (*Icterus galbula*), a bird ranging from Canada to Mexico, is a well-known example. It has the head, throat and wings of black; the lower back and all the under parts are orange, deepening into vermilion on the breast. The orchard oriole (*I. spurius*) resembles the Baltimore oriole in habits, but is found mostly around orchards. The male is black and reddish, while the female is olive and yellow.

Ostrich (*Struthio camelus*). A flightless bird inhabiting the southern parts of Africa. The ostrich is related to the emus and rheas. The wing muscles are reduced, and there is no keel on the breastbone as there is on most other birds. The African ostriches formerly furnished most of the well-known plumes which were used in decorating hats, but the use of them has been reduced in recent years. Ostrich farms have been started in South America and in California. The eggs, which are the largest of any living bird, are laid in the sand and are incubated by the heat of the sun.

Otter (*Lutrinae*). Carnivorous mammals related to the bear. They furnish valuable furs, the skins of the sea otters of the Pacific coast being the most valuable. All are fond of the water, the sea otter spending most of its time in the sea.

Owl (*Strigidae*). The popular name of a group of nocturnal birds of prey. The order *Strigidae* is a sharply defined one.

The head is extremely large; the eyes huge and directed forward; the bill short and stout; the apertures of the ears very large; the legs feathered; the toes four in number, the outer one capable of being directed backward. The plumage is remarkably soft, the feathers of the face forming disks around the eyes. The owls are cosmopolitan, ranging over the whole globe. They feed on small mammals, birds, fishes and insects, swallowing the hair, bones, feathers and scales. This they afterward disgorge in the shape of pellets. They nest on the ground, among rocks, in hollow trees and in buildings, while some resort to the old nests of other birds. They lay from two to five roundish, white eggs.

Oyster (*Ostrea* spp.). A familiar shellfish, possibly the most valuable of all of the molluscs. There are various species in all parts of the world, but the best is the American species, which now is found from Cape Cod to the Gulf of Mexico. Formerly it extended to the coast of Maine, and even now there are scattered beds in the Gulf of St. Lawrence. The oyster grows in shallow water, fastening its shell to some rock or shell, and in this way large beds are formed. They are also planted; that is, the young are taken and placed in favorable situations for rapid growth. The great enemies of the beds are the "drill," a small snail that bores holes through the shell in order to obtain the flesh, and the star-fish, which destroys large numbers. The oyster yields comparatively little nourishment, yet it is eaten extensively. The European oyster is smaller than ours and has a coppery taste. Our species have the sexes separate; in the European species they are united in the same individual.

Allied to the true oysters are the pearl oysters, especially abundant around Ceylon. These have the interior of the shell lined with mother-of-pearl, and when foreign particles get between body and shell they are covered with the same substance, thus forming the pearls used for adornment. These oysters are obtained by diving. The animal matter is allowed to rot, leaving the pearls behind. The shell is also of value, furnishing material for knife handles and buttons, though most of our pearl buttons are now made from the shells of fresh-water mussels from the Mississippi Valley.

Parrot (*Psittaci*). A group which includes the parrots proper, the cockatoos, paroquets, macaws, lories and nestors. In true parrots the upper mandible, which is toothed, is longer than it is high. They have a short, rounded tail. These birds combine, with the beauty of their plumage, a nature of great docility. Parrots have the faculty of imitating the human voice in a degree not possessed by other birds. They are found chiefly in Africa, from whence we get the gray parrot, the best talker. South America, which is particularly rich in species, furnishes the well-known green parrot; and North America is the home of a single species, the Carolina parrot. The parrots are forest birds and are adepts at climbing, using for that purpose both the feet and the bill. Their food consists of seeds and fruits.

Partridge (*Phasianinae*). A European member of the grouse family, from which the name has been transferred to the quail in the Southern States, and to the ruffed grouse farther north.

Peccary (*Dicotyles* spp.). Hog-like animals found in the tropical regions of the New World. They have short tusks which are used in hunting. They frequent forests, and are usually seen in groups. At night they feed on corn, inflicting considerable damage on the crop. They are also fond of reptiles and other small animals. Jaguars and pumas are their enemies.

Pelican (*Pelecanidae*). Fish-eating swimming birds of the warmer regions, with a large pouch of skin between the halves of the lower jaw. In fishing they swim, striking the surface of the water with the wings, scooping the fish into the pouch, and later retiring to the shore to devour them. There are two species in the Gulf States—one white, the other brown, in color.

Penguin (*Impennes*). A group of antarctic birds, with wings very small and hard and covered with small stiff feathers of a bristly nature, absolutely useless for flight. The birds swim well, using both their webbed feet and their wings. There are about eighteen species, entirely confined to the Southern Ocean and the antarctic regions, where they correspond to the auks and divers of the northern seas. During the breeding season they resort to rocky islands in immense numbers, and stand erect with their eggs under them. Their food consists chiefly of fish.

Perch (*Percidae*). The common name for several species of fish in both fresh and salt water, all of which are characterized by spines in the fins and by hard scales. The name properly belongs to the fresh-water species, which are of some value as food.

Petrel (*Procellariidae*). A species of birds related to the albatrosses and varying in size from six inches to three feet in length. All of them live on the high seas, and many of them will follow a ship for days for the scraps thrown overboard. At night they follow close behind the stern of the vessel.

Pheasant (*Phasianidae*). Bright-colored birds with long tails. They were originally native to the Old World, but have been introduced into the United States. Here they have become pests in some localities. They cross readily with the domestic fowls, the hybrids being known as "peros." Pheasants are tasty as an article of food and are valued as game birds.

Pigeon (*Columbae*). A group of birds, including about 300 species, distributed in nearly all parts of the world. All of them are so much alike that no one is in any doubt about the membership of any form in the group. Most of the domesticated varieties, with their great differences in form—differences which in other groups would be considered as distinct species or even genera—are derived from the rock dove. Among the interesting species are the passenger pigeon, which eighty years ago formed immense flocks over the whole of the eastern part of our country, but which are now extinct. The mountain witch of Jamaica is one of the most beautiful of birds. The largest member of the group was the dodo of islands in the Indian Ocean, which became extinct before 1681, partly because it lacked the power of flight. It was somewhat larger than a turkey, with the same external appearance, but with head and legs different. See Dodo.

Platypus. Same as duckbill (which see).

Polecat (*Putorius* spp.). A name common to several species of the weasel family. The common polecat is found in Europe. It is about seventeen inches long, the tail six inches. The color is dark brown. It is nocturnal, sleeping during the day and searching for its prey at night. It is destructive to poultry, rabbits and game. It has glands secreting a fetid fluid, somewhat like that of the American skunk, which it ejects when irritated or alarmed. Its fur, which is imported in large quantities, is known as "fitch." Its hairs form superior artists' brushes.

Porcupine (*Hystricidae* and *Erethizontidae*). Large rodents characterized by having some of the hairs in the form of large spines or quills. Usually the hairs are flat on the animal's back, but when disturbed the porcupine rolls itself into a ball and all the quills stand outward, forming a very good defense. The quills come out very easily, but there is no truth in the statement that the animal has the power to shoot them. Our American species (*Erethizon dorsatum*) has quills about three inches long. It feeds upon the bark of trees, doing much damage to the vegetation. Some of the European and African forms have quills reported to be a foot long.

Porpoise (*Delphinidae*). A very small whale belonging to the group of dolphins, usually about four or five feet in length. It is dark gray above and almost white below. The greater part of its diet is composed of small fish, and the porpoises are commonly seen following large schools of fish. Like all whales, porpoises must come to the surface of the water to breathe.

Prairie Dog (*Cynomys* spp.). Small rodents of the squirrel family, found on the plains east of the Rocky Mountains. They resemble their allies, the marmots, in appearance, having well-developed claws on all the toes of the forefeet and shallow cheek pouches. The best known species is about one foot in length, and has a tail of about four inches. On the upper surface it is reddish-brown variegated with gray. These animals live together in great societies on those portions of the prairies where the buffalo grass grows luxuriantly. Here they excavate burrows in the ground near to each other and when the little creatures are out, quite a busy scene is presented. The name is given them on account of a resemblance between their cry and the bark of a small dog.

Primates. The highest order of mammals, containing the apes, lemurs and man. The forefeet are usually grasping organs, while the hind feet are walking (as well as grasping, in some cases) organs.

The development of the brain in this group is the greatest of any in the animal kingdom.

Ptarmigan (*Lagopus* spp.). Grouse-like birds found in the arctic regions and on high mountains. They are desirable game birds and are hunted. They nest in thickets on the ground. Their food is buds, insects, berries and roots. The ptarmigan has two color phases. It is reddish-brown in the summer, but turns to an almost snow white in winter.

Quail (*Colinus virginianus*). A game bird, also called "bobwhite" from the sharp whistle of the male. It inhabits the greater part of central North America, preferring the open fields. Its nest is usually placed on the ground and is made of grasses and other vegetation. The eggs number about twelve, and two broods are produced each season.

Rabbit. See Hare.

Raccoon (*Procyon* spp.). Nocturnal carnivorous animals of both North and South America. The fingers and toes are exceptionally long, a fact which greatly aids the raccoon to catch its favorite food—fish. During the day the raccoon curls up in a tree to sleep.

Raven (*Corvus corax*). Large birds resembling crows. They were formerly found over most of the United States, but have been driven out of all but the western regions. They are destructive birds, eating almost anything. They are remarkable for their long life, some ravens having been known to exist for over seventy years. They are among the few birds that can imitate human speech.

Reptiles (*Reptilia*). A large group of vertebrates, including lizards, snakes, turtles and crocodiles, and a large number of extinct forms, such as the dinosaur. Reptiles have a scaly skin, breathe by lungs and have blood which maintains the same temperature as their surroundings. All reptiles produce eggs, but some of the snakes retain them in the body until they are hatched. Reptiles and birds resemble each other in several points, so that they are united in a group of *Sauropsida* (reptile-like). Snakes and lizards are closely related, both having the scales as horny plates on the outside of the skin; they have a movable bone inserted between the lower jaw and the skull. In the crocodiles and turtles, this quadrate bone is present but immovable. The turtles have the body inclosed in a bony case, the upper half being formed of the ribs united to the skin, the lower of plates developed in the skin. In the crocodiles the scales are strengthened by the formation of bone beneath the horny portions. Most reptiles have teeth, but all of the turtles lack them, the jaws being covered with horny sheaths. Some of the snakes and a single lizard (the Gila monster) are poisonous, the poison glands being developed in the mouth.

Rhinoceros (*Rhinocerotidae*). The name of a family of mammals, represented by nine living species, characteristic of Africa south of the Sahara, India, Borneo and Java. They have large, unwieldy bodies; short, thick legs, terminating in large pads, with hoof-bearing toes; large, elongated heads, with a long horn or horns springing from the snout in existing forms; small eyes and ears, and short tails. Their hide is extremely thick. Five species, all possessing two horns, belong to Africa. Of these, the white rhinoceros is the largest, attaining a length of over twelve feet and a height of nearly six feet; but the black rhinoceros is best known. The Asiatic species are four. Their hide has much the appearance of armor plates. They are smaller, and two of the species possess double horns, and two a single one. The Indian rhinoceros, a one-horned species, is the one usually seen in menageries in this country. It leads a tranquil, indolent life, wallowing on the marshy borders of lakes and rivers. Owing to the keenness of its smell and hearing, the rhinoceros cannot be easily attacked; but, when brought to bay, it charges with great fury and impetuosity.

Robin (*Turdus migratorius*). The American robin is a familiar bird in all parts of the country. It is about ten inches in length, is of a dull brownish-gray above and has a breast of rusty red. It is one of the birds which appears earliest in the spring. John Burroughs called it, of all our birds, "the most native and democratic." Although it is usually thought that the robin winters in the South, probably very few migrate to any great distance, most of the species spending the winter within a few miles of their nesting site.

Rodents (*Rodentia*). A large group of mammals containing such forms as the rats, mice, squirrels, rabbits, marmots and beavers. The most characteristic thing about the group is the nature of the teeth. There are no canine teeth, and the incisors are used in their well-known gnawing acts. The incisor teeth continue to grow throughout life, being kept down only by gnawing. Although the rodents are mostly burrowers, some forms, as the vole and muskrat, have become partly aquatic; others, such as squirrels, are tree dwellers. Rodents have caused much economic damage in Europe and America.

Sable (*Mustela* spp.). A carnivorous mammal allied to the common marten and pine marten, found chiefly in Siberia and Kamchatka, and hunted for its fur. Its length, exclusive of the tail, is about eighteen inches. Its fur, which is extremely lustrous, and hence of the very highest value, is generally brown, grayish-yellow on the throat, and with small grayish-yellow spots scattered on the sides of the neck. It is densest during winter, and owing to the mode of attachment of the hairs to the skin, it may be pressed or smoothed in any direction. A North American species, the pekan (*M. pennanti*), is sometimes known as the "fisher." The skins of all these varieties are frequently dyed and otherwise manipulated to imitate the true Russian sable. Sable hair is also used in the manufacture of artist's pencils. Sable fur has been of great value since early times.

Salmon (*Salmonidae*). Well-known fishes, forming a large part of the food supply of the world. The salmon inhabits both fresh and salt water. It generally reaches a length of from three to four feet, and an average of from twelve to thirty pounds, but these limits are frequently exceeded. The adult is bluish-white on the back and head, and lighter on the sides and belly.

The eggs hatch in the headwaters of some fresh-water stream, and the young usually remain in the shallow portions of this stream for a year or more, at which time they migrate to the sea. When the season of its migration arrives, the fins have become darker and the fish has assumed a silvery hue. It is now known as a "smolt" or "sálmon fry." The smolts now congregate into shoals and proceed seaward. On reaching the estuary they remain in its brackish water for a short time, and then make for the open sea. The smolt, leaving its native river as a fish weighing perhaps not more than two ounces, after three months' absence may return to fresh water as a "grilse," weighing four or five pounds. In the grilse stage, the fish is capable of depositing eggs. After spawning in the fresh water the grilse again seeks the sea in the autumn, and when its second stay in the ocean is over it returns, after a few months' absence as an adult salmon, weighing from eight to ten pounds. For the purpose of breeding, the salmon returns to the same river in which it passed its early life. The salmon industry is one of the great food industries. There are large fisheries both in Europe and in western America between the latitudes of 45° and 75°.

Sardine. See Herring.

Sea Anemone (*Anthozoa*). Flower-like animals belonging to the group *Coelenterata*. All are sea forms and are found attached to piles and floating timber. From their attached positions they extend arms or tentacles in all directions in search of food, which consists of microscopic organisms. The power of contraction is great; when irritated, the sea anemone contracts violently and at the same time sends out long threads from small holes in the body. These threads bear stinging cells, capable of killing small animals.

Sea Cucumber. See Echinoderms.

Sea Lion (*Otariidae*). Aquatic mammals, relatives of the seals and walruses. The sea lion differs from the seal in having the hind limbs less modified into a tail-like structure, and in having an external ear. Although the group *Otariidae* has a wide distribution, sea lions are mainly antarctic. Many of the "seal skins" of commerce come from sea lions.

Seal (*Phocidae*). A family of aquatic carnivorous mammals in which the legs have become modified into flippers, which are of little use in progressing on land, but which are well adapted for life in the water. All species of seals are flesh eaters, and make great havoc in schools of fishes, although they eat such forms as sea birds, molluscs and crustaceans as well. They are, in turn, prized as food by the Eskimos.

The fur seals are of most importance in the Pacific Ocean where they are found from southern California to the Aleutian Islands. At one time the population of Commander and Pribilof Islands was estimated at 3,500,000 seals, but at present this number is much smaller, due to exploitation by the sealing industries.

Seaurchins. See Echinoderms.

Shad (*Clupea* spp.). A migratory fish of considerable food value. In the spring it ascends all the rivers of our eastern coast to lay its eggs. It is closely related to the herring, but is much larger. This fish has an unusually extensive development of certain bones which keeps it from being a good food fish.

Shark (*Selachii*). A group of very simple fishes in which the skeleton is entirely of cartilage, no bone being developed. The gill openings have no covering (operculum) as in other fish, and open separately by five slits on each side of the neck. The mouth is on the bottom of the head and not at the extreme front. This is possibly correlated with the mode of eating. The tail has two lobes, of which the top is much longer. The skin of most species is composed of a number of small plates, each of which bears a small spine. Formerly this was used commercially in place of sandpaper. The skins of certain sharks are used in the manufacture of pocket books. The size of sharks varies from the small dogfish forms, which average perhaps two feet, to the great basking shark, which is some forty feet in length. Most of the species are voracious, but the tales of man-eating sharks are exaggerated and overdrawn. The flesh of some of the smaller sharks is edible and is sold under the name of "grayfish"; but the use of it in this country is limited.

Sheep (*Bovidae*). Animals belonging to the hollow horned ruminant family. Wild sheep are common in Asia, where they are often found in large herds in the mountainous regions. In America the bighorn sheep (*Ovis canadensis*) is found in the Rocky Mountains from Mexico to northern Canada. Marco Polo's sheep (*Ovis poli*) is one of the finest species of wild sheep known. This large race is present in Turkestan and has been known to exist since the thirteenth century. It reaches a length of over six feet and the horns often attain a length of five feet.

Domesticated sheep have always been known. They were probably tamed in Asia and introduced into other parts of the Old World before history was written. The American breeds of domesticated sheep come chiefly from British and Spanish races. The Shropshire is a popular breed in the Middle States and is a good mutton sheep. The most important wool sheep is the Merino breed. Although this is of Spanish origin, it is found today largely in America and Australia, where its fine wool is a product of great importance. In addition to wool and meat products sheep are of considerable importance to farming because of the manure which they produce.

Shrew (*Soricidae*). The smallest of mammals. They are mouse-like in appearance, but belong to a different order. Shrews are found in fields, meadows, gardens and woods, and even in semi-aquatic places where they feed on worms and insects. They are usually found under logs and stumps. The most common shrew in the United States is the mole-shrew (*Blarina brevicauda*) whose mole-like habits are responsible for its name.

Shrimp (*Decapoda*). The common name for a large number of small crustaceans allied to the lobster and crab, mostly sea dwellers. In many countries they are an important article of food and in this country they are widely used. One or two southern species form the basis of shrimp salad. Shrimps are abundant off the American coasts and are becoming an important fishery.

Silkworm (*Bombycidae*). A term applied to the larvae or caterpillars, of several species of moths. The common silkworm moth, the most important, is a native of China, where it has been cultivated from a remote period. The caterpillar (silkworm) is yellowish-gray, and when full-grown is about three inches in length, with a horn-like projection on the last joint of the body. It feeds upon the white mulberry. The silk is produced in a pair of glands on the floor of the body which contain a gelatinous substance, and become much enlarged at the time when the animal is about to spin. These silk-glands unite at the mouth to form a common duct termed the "spinneret." Through this tube the semi-fluid substance is ejected and, on coming in contact with the air, hardens into the fiber so largely used in commerce. The caterpillar employs the silk in constructing a cocoon in which it assumes the pupa state. The pupa is usually killed by plunging the cocoon into hot water, because the natural exit of the moth is injurious to the silk. After the pupa is killed the silk is reeled from the cocoon and sent to the market as raw silk. The color of the silk varies from a bright orange to almost white. In Europe, some moths produce one generation, others two generations, annually. A valued variety is the novi race of Italy, which spins a large, white, oval cocoon. The Japanese have several varieties, including an oak-feeding silk moth, producing a green cocoon, the silk of which is much used for embroidery. There are also different kinds in China and India.

Skate (*Selachii*). A fish, closely related to the shark, which it resembles, except that the body of the skate is flattened from top to bottom. The mouth and gill slits are all on the bottom. The skates are mainly bottom feeders, eating principally clams and other animals which bury themselves in the mud. In Europe some of the smaller species are used as articles of food, but the practice is not common in America. The sawfish is a skate having the head armed with a long snout which is provided with teeth on the sides. Another species, the torpedo, is provided with sets of muscles capable of giving a powerful electric shock.

Skunk (*Mephitis* spp.). A carnivorous mammal, usually marked with black and white in a striking manner. It is nocturnal, feeding on whatever it may find, and is especially fond of poultry. It is defended by the secretion of a gland near the vent, and can eject the offensive secreted fluid at will.

Sloth (*Bradypodidae*). A large mammal belonging to the edentates, or animals with imperfect teeth. It is a tree dweller which lives, back downward, hanging by its strong claws from the limbs of trees. It feeds upon the leaves, and its slow motions are said to give it its common name. It occurs in the forests of tropical America.

Snail (*Gasteropoda*). A common name for molluscs which have the body enclosed in a coiled shell. The land-dwelling forms have a slight shell, into which the whole body can be retracted. They feed exclusively on vegetation, which they rasp by means of a long ribbon, just inside the mouth, the surface of which is covered with thousands of minute teeth, so that the whole is a flexible file. The animal creeps about on a broad sole, and has four tentacles on the head, one pair of them bearing the simple eyes at the tip. Snails do considerable damage where they are numerous. One species is eaten by many people in Europe, especially in France and Italy. Over ten thousand species are known.

Snake (*Serpentes*). A group of limbless reptiles, found in almost all parts of the world except the polar regions. They have a rounded body, scaled above but with broader plates or scutes on the lower surface. The mouth can be opened very wide, and the jaws are armed with teeth pointing backward, which are of great assistance in forcing large animals down the throat. Most of the species are so colored that they are inconspicuous in their natural surroundings, but most of the poisonous species have no such protection. The largest of the snakes are the pythons of India and Africa. The most poisonous species are the fer de lance of the West Indies

and the karet of India. One group is entirely aquatic, living in the middle of the Indian and the tropical Pacific Oceans, and bringing forth its young alive. These are also poisonous, and have a flattened tail for swimming.

Sole. See Flatfish.

Sparrow (*Fringillidae*). This term was originally applied to the common English, or house, sparrow, but has been extended to include many small birds of different kinds. Most of the sparrows are small, inconspicuous birds with a coloration of dark brown. The English sparrow (*Passer domesticus*) is a common resident of northern Europe and Asia, and has been introduced into North America. Since 1850, when the first English sparrows were brought to this country to protect the trees against insect pests, these birds have spread to all parts of the United States and have themselves become pests, eating grain and other food crops. They are very destructive in gardens. The lark sparrow, or lark finch (*Chondestes grammacus*), is not really a sparrow, but is called so because of the thick bill. The head is marked with black and white stripes. Its song is very pleasant, and can be recognized by the low purr. The fox sparrow (*Passerella iliaca*) is a larger bird, and has red plumage. Its song, which is quite pleasant, is heard only in the spring and fall, as the bird is only a migrant in this country. The vesper sparrow (*Passerculus* spp.), often called the grass finch, is recognized by the outer tail feathers, which are exceptionally white. It receives its name because it is found singing late in the afternoon. The song sparrow (*Melospiza melodia*) is a moderately large bird of six or seven inches in length. The white underparts have black or brown markings which fuse in the center to form a large blotch. Its song is very sweet and melodious. The crown sparrows (*Zonotrichia* spp.) often have conspicuous head markings colored with yellow or white.

Native sparrows do little damage to grain crops as compared with the English sparrow. They do eat many seeds and fruits, but these are usually the seeds and fruits of weeds.

Spiders (*Arachnida*). A group of animals with jointed bodies and legs, the bodies divided into two regions, the anterior of these bearing four pairs of legs and two smaller pairs of appendages. The most anterior of these are the poison claws. They have a poison gland in the base, while the end of the claw tapers to a point, serving as a hypodermic syringe. The front of the head has from six to eight simple eyes. The hinder half of the body, the abdomen, is without appendages, save for two or three pairs of very small projections, the spinnerets. Each of these has numbers of openings at the tip through which a fluid is forced at will. This hardens immediately it comes in contact with the air, and furnishes the silk of which the web is woven. Fine as it is, this silk is really a cable, being made of numbers of finer threads, one for each opening in the spinnerets. Spiders breathe by means of sacks—so-called "lungs"—on the lower side of the abdomen. They use the silk for making webs, for cocoons for the eggs, nests, and in some cases for parachutes for flying. Each species makes its own type of web. Our common house spider is the same as that of Europe. The largest species we see is the one found occasionally in banana bunches. The tarantula has the greatest reputation because of the unfounded belief that its bite causes madness which can be cured only by music. So far as is known there is only one species which can cause serious effects by biting man, and even these cases are not sufficiently authenticated.

Sponge (*Porifera*). Lowly organisms which live attached to stones and other submerged objects, and depend on the currents of water to bring them food. Although most of the sponges are found in the ocean, there are a few fresh water forms. The body is perforated with many holes through which the water flows, bringing food. A large opening at one end allows the water to leave the body. Thus there is a continuous stream of water flowing through the body at all times. Sponges have skeletons of lime and of a horny substance called "spongin." The spongin skeletons are used commercially as bath sponges.

Squid (*Tenthoidea*). A marine mollusk, closely related to the cuttlefish. The body is barrel, or cigar-shaped, and has ten long arms equipped with suckers projecting in front. The head has two well-developed eyes which are quite similar to the eyes of the higher animals. When disturbed, squids give off a quantity of an inky substance which acts as a screen and aids them in their escape. The Japanese formerly made use of squid's ink in the manufacture of a famous ink used in reproducing their drawings. The size of squids varies; most of them are less than two feet, but giants have been reported from time to time with bodies twenty feet long. These giants were common about 1875, but of late years have not been seen. Squids are nervous animals and will not live long in captivity.

Squirrel (*Sciuridae*). A group of rodents, too well known to need description. They are abundant in all of the Northern Hemisphere, living in trees and feeding largely on nuts. There are several species in the United States, the fur of the larger kinds having considerable value. Closely related are the ground squirrels, or chipmunks, and the flying squirrels, which really do not fly but glide by means of a parachute of skin extending between the legs of each side

Starfish. See Echinoderm.

Stoat. See Weasel.

Stork (*Ciconiidae*). A family of birds, chiefly confined to the Old World. The true storks number six species, ranging over Europe, Asia and Africa, and found also in South America. They resemble the herons, but are more robust, and have larger bills, shorter toes, with a nonserrated claw on the middle toe. They inhabit the vicinity of marshes and rivers, where they find food consisting of frogs, lizards, fishes and even young birds. They are migratory, arriving at their breeding haunts in the early spring and departing again in the autumn. The white stork is common in Europe, constructing a large nest, most frequently on the chimney of a cottage.

Swallow (*Hirundinidae*). Birds characterized by the very wide gape of the mouth, to which the common name may allude. All are noted for their graceful flight. They feed almost exclusively on insects, hence are very valuable. Among our common swallows are the purple martin, the cliff swallow, the barn swallow and the sand martin. The so-called "chimney swallow" is, strictly, not a swallow but a swift.

Swan (*Anatidae*). Swimming birds, closely related to the ducks and geese, with long and slender neck, bill about as long as the head, and with a soft cere. Nine species are known, one coming from Chile, the black swan from Australia, and the others from the Northern Hemisphere. We have two white species, the whistling and the trumpeter swans, but the tame species are all of European origin. Once swans were bred for the table, but now they are bred solely as ornamental birds for lakes and pools.

Swift (*Cypselidae*). Aerial birds which seldom come to the ground, except at night. They are tireless flyers, usually seen in pursuit of insects which they continually hunt. The coloration is almost always dull, either black or brown. The swifts are usually seen in groups. Nests are placed in inaccesible places, such as the sides of rocks, chimneys and caves. See Swallow.

Swine (*Suidae*). Animals closely resembling the common domestic pig, which is a good example of the group. Swine are rather commonly distributed over the world. The domesticated variety is too well known to require description here. Of the wild type, the wild boar (*Sus scrofa*) is the most commonly known. It was formerly present over Europe in large numbers, but has been scarce since the seventeenth century. In this species the tusks are well developed. The young are marked with brown stripes which remain for several months after birth. The African wart hog (*Phacochoerus aethiopicus*) receives its name because of the large facial growths which resemble warts. In this species there is a growth of long hair down the middle of the back, and the tusks are well developed in both jaws. Closely related to the *Suidae* are the *Hippopotamidae* (see Hippopotamus) and the American peccaries. See Peccary.

Tapir (*Tapirus* spp.). A genus of hoofed animals with an odd number of toes on the hind feet. All are tropical, some living in Asia, others in America. All are bulky beasts, somewhat resembling swine in appearance. They have the snout prolonged into a flexible proboscis with the nostrils at the tip. Their flesh is said to be good to eat.

Tarantula (*Theraphosidae*). Hairy spiders of tropical and sub-tropical countries. They are often brought into the United States on fruit. The tarantula eats insects and other small animals. The seriousness of the bite of the tarantula is overestimated; it is painful, but seldom proves fatal. This spider is nocturnal in habits. During the day it remains in a silken tube in the ground.

Tern (*Sterninae*). Terns, or sea swallows, are familiar birds on the seashore. They inhabit the entire Northern Hemisphere and breed in sandy, isolated regions. Terns usually are gray above and white below, with black markings on the head. See Gull.

Thrush (*Turdidae*). Attractive birds of moderate size, found all over the country. The true thrushes are represented in America by the American robin, bluebird, nightingale and others. The group contains many of the best songsters. The wood thrush (*Turdus mustelinus*) of the eastern United States is olive green above and almost white, with brown spots on the belly. This is the best singer of the American forms. The brown thrush, or thrasher, receives its name from the fact that it is noisy. The hermit thrush (*Hylocichla pallasii*) is a visitor. It breeds in the far north and winters in the south. See Robin; Bluebird; Nightingale.

Tiger (*Felis tigris*). The largest and most dangerous of the cats, slightly exceeding the lion in size, and far surpassing him in destructiveness. It is purely Asiatic in its habitat, but is not by any means confined to the hot plains of India, though there it reaches its highest development, both of size and coloration. The full-grown male Indian tiger measures from nine to twelve feet, and the tigress from eight to ten feet, from the nose to the tip of the tail. The ground color is rufous or tawny yellow, white on the ventral surface, with vertical black stripes or elongated ovals and brindlings. Though possessed of immense strength and ferocity, the tiger rarely attacks armed men, unless provoked, but often carries off women and children. When pressed by hunger or enfeebled by age and incapable of dealing with larger prey, like buffaloes, the tiger prowls around villages and, having once tasted human flesh, becomes a confirmed man-eater. In a government report it is stated that "one tigress caused the desertion of thirteen villages, and 250 square miles of country were thrown out of cultivation."

The jaguar is sometimes called the "American tiger."

Toad (*Anura*). The common name of any amphibian without a tail or teeth, and with a warty skin. They are common in most parts of the world, there being few in the Australian region, however. They are mostly nocturnal and, as they feed on insects, they are among the best friends of man. The warts are caused by glands in the skin which secrete an acrid fluid. Warts constitute the chief means of defense as few animals will touch them. It is scarcely necessary to say that toads are perfectly harmless to man, and that they cannot cause warts.

Tortoise (*Testudinidae*). Slow moving reptiles with a heavy armor of horny plates. The chief distinction between turtles and tortoises seems to be one of habitat, the turtles usually being considered aquatic animals, while the tortoises are thought of as terrestrial forms; this distinction, however, does not always hold. One of the most common and familiar members of this group is the American box tortoise (*Cistudo carolina*). The name was given because of the drawing of the body completely within the hard covering and closing the ends by hinged portions of the "shell." Tortoises sometimes attain great sizes. Among the largest are the giant tortoises (*Testudo*) of the Galapagos Islands. Specimens attain a length of four feet and a weight of over 500 pounds.

Trogon (*Pharomacrus mocinno*). A long-tailed bird found in the mountainous regions of South America. The back and wings are of a greenish tinge; the underparts are brilliant crimson. A full crest lends an appearance of splendor to the bird. In former times the native chiefs used the long tail feathers for decorations.

Trout (*Salmonidae*). A common name for several fishes with soft, rayed fins and a small fin without rays on the back, behind the large fin. They have very small scales. All are excellent eating, and all are regarded as game fish. Our brook trout is typical. This thrives in the coldest and clearest streams, laying its eggs in December or January. Other species in North America are the lake trout and the salmon trout in the East and the rainbow and the Dolly Varden trout in the West. Europe has its own trout. All of the species belong to the Northern Hemisphere, but they have been introduced into Australia and New Zealand.

Turkey (*Meleagrinae*). A large scratching bird, a native of America from Canada to Central America. It is known now chiefly in domestication, but is still found wild in some parts of the United States. The tame birds differ some in appearance from the birds in a wild state. The name was given under the misapprehension that they came from Turkey.

Turtle (*Chelonia*). The common name for one of the reptiles. They are remarkable for having the body inclosed in a hard case, composed above of the enlarged ribs, and below of several large, bony plates. In some the head and legs can be retracted inside this shell. Over the outside of the case are horny plates which, in the hawkbill turtle, are of value, as they afford the tortoise shell used for combs. Turtles never have teeth, the edges of the jaws being covered with horny material. Most of the species are carnivorous. Some are terrestrial, some occur in fresh water, and some in the sea. The largest species are the marine leatherbacks of the tropics, which occasionally drift north to New England, and the giant species occurring on the Galapagos Islands, off the west coast of South America, and on some islands in the Indian Ocean. The marine green turtles are favorites with epicures, as are the terrapins of our eastern coast. Most species are inoffensive, but our soft-shelled turtles and snapping turtles are savage animals.

Vampire (*Phyllostomidae*). Blood-sucking bats of the tropical parts of North and South America. The front incisor teeth are much elongated into a sharp structure which can easily penetrate the skin of other animals. Vampire bats attack mammals such as horses, cattle and even man. The victims are usually attacked while asleep. The teeth are so sharp that often the danger is not sensed until considerable blood has been lost and the bat has departed.

Vertebrates. One of the great groups of the animal kingdom. The vertebrates have a backbone, or vertebral column, which protects the spinal cord, and terminates in front in the skull containing the brain. The alimentary canal lies entirely below this central skeleton, and the organs of respiration are always connected with this, being either gills in openings passing from the throat to the exterior, or lungs connected with the throat by a windpipe. The heart is always below the digestive tract, usually beneath the throat, but in the higher forms it is carried back into the chest. Some lack legs or their equivalent fins, but most have two pairs of these structures, and the aquatic species have also fins in the middle line of the back and belly. All reproduce exclusively by eggs, there being no cases of division or budding, so common in the lower divisions of the animal kingdom.

Wallaby (*Macropodinae*). A primitive mammal, similar to the kangaroo. Wallabies are found only in Australia and a few adjacent islands. The rock wallaby (*Petrogale* spp.) is able to leap with considerable skill in very rocky and dangerous places, using its tail as a balancing organ.

Walrus (*Trichechidae*). A marine carnivorous mammal, closely related to seals and sea lions, with enormous down-turned tusks, or canine teeth, projecting from the upper jaw, which sometimes reach a length

of sixteen inches beyond the sockets. Walruses have a thick, clumsy body, deepest at the shoulders, and feet that are adapted for swimming. They reach a length of twelve feet or more, and a weight of 2,200 pounds. There are two species, one in the Atlantic and one in the Pacific. The Atlantic form is found on the coast of Labrador and Hudson Bay, but formerly extended farther south. They feed largely on clams and other molluscs which they dig from the sea bottom with their tusks. They are hunted for their hides and oil.

Wasps (*Hymenoptera*). A group of insects with two pairs of wings, the hinder part the smaller, and a well-developed sting, with a poison gland connected, at the hinder end of the body. It is not easy to frame a definition in common words that will separate them from the ants and the bees. Some are solitary, some form colonies in which the individuals work together for the common good. Among the first are the digger wasps, which excavate holes in the soil, or in wood, which they store with insects that they have paralyzed with the sting; then they lay their eggs in the mass, so that the young, on hatching out, will have abundant food. Other solitary forms are the mud daubers, which build nests for the eggs by sticking mud to beams in barns and in other similar places. The social wasps make a nest in common, sometimes in the earth, but the well-known yellow jackets, or hornets, make paper nests from bits of decaying wood which they chew into a real paper pulp. In the colonies the males die at the approach of winter, but the females live to form a new colony in the spring.

Weasel (*Putoris* spp.). Small flesh eaters found in Europe and in America. In Europe they are called "polecats" and "stoats," depending upon the species. In our Eastern States the common weasel (*P. noveboracensis*) is of a brownish hue above, and white below. In the winter the color changes to pure white. It is noted for its ferociousness, eating voles, mice, rats, poultry and other small animals. In turn it is preyed upon by hawks and other birds of prey. It is most active at night.

Whale (*Cetacea*). The popular name of the larger cetaceans, particularly of all those belonging to the families *Balaenoideae* and *Physeteridae* or *Catodontidae*. In the *Balaenoideae* the head is of enormous size, but is entirely destitute of teeth, instead of which the palate is furnished with an apparatus of baleen, or whalebone, for the purpose of straining out of the water the small crustaceans, which form the food of these whales. The elasticity and heaviness of whalebone are well known. The plates of it in the mouth of a whale are very numerous, several hundreds on each side of the mouth, and they are very closely placed together, so that the mouth is filled with them. The head of whales usually occupies from a third to a fourth of the whole length. The lower surface of the true skin extends into a thick layer of blubber, an open network of fibers, in which fat is held. The blubber is from one foot to two feet in thickness, the whole mass in a large whale sometimes weighing more than thirty tons.

The most important species is that known as the right, or Greenland whale. It inhabits the seas of the northern parts of the world, and abounds chiefly in the arctic regions. It attains a size of sixty or seventy feet in length. It was formerly supposed that the Greenland whale was an inhabitant of the southern as well as the northern parts of the world; but the southern, or cape whale, is now regarded as a distinct species, the head being smaller in proportion than that of its northern relative, and the color a uniform black. The main physical characteristics of the whale are its distorted jaws, with upward directed nostrils, its great bulk and rudimentary limbs. The huge bulk of the creature is driven forward by the flexible caudal fin, and while the body is rigid in front, it exhibits great mobility behind. The blowholes are placed on the top of the head, and the animal can respire only when these are above water. The larger whales travel at the rate of about four miles an hour, but when pursuing their prey or goaded by pain, they rush through the water at a much greater pace. They are aided in this by the broad and powerful tail, which is their chief organ of locomotion. Instead of being vertical, as in the fishes, this is horizontal, and the larger species can command immense driving power. The tail is also used as an offensive and defensive weapon. The smooth, shining skin is immediately underlaid by a thick coating of blubber, the great object of the whalers. This is at once dense and elastic, and while it preserves the animal heat it also serves to reduce the mighty bulk of the whale and to bring it nearer to the specific gravity of the element in which it spends its existence. It might be thought that the whale, with its vast bulk, would need sea creatures of a high organization to nourish it; but this is not so. Its chief food consists of minute molluscs, and with these its immense pasture grounds in the northern seas abound.

Whippoorwill (*Antrostomus vociferus*). A bird widely known on account of its oft-repeated cry of "whip-poor-will." It is not often seen, although abundant in damp woods of the eastern United States. It usually rests on the ground during the day and is active at early nightfall, sending forth its cry, and also coursing low over the grass in search of insects. It is about ten inches long and of plain colors, being grayish, much variegated with black and buff. Its bill is very broad, its mouth large and provided with a tuft of long bristles. It builds no nest, but deposits its eggs on leaves or in a slight depression in the ground. To the same family belong the chuck-will's-widow and the night-hawk.

Wildcat (*Felidae*). The true wildcat (*Felis catus*) is found only in northern Europe and Asia. It is a striped animal, quite similar to other members of the cat family. In America the name wildcat is applied to almost any cat other than the domestic house cat, the lynx and puma being the most common.

Wolf (*Canis* spp.). Several species of carnivorous animals belonging to the dog family. The common wolf is about five feet in length, including the tail, and about thirty-two inches in height at the shoulders. The muzzle resembles that of a sheep dog; the ears are upright and pointed, and the eyes are set obliquely. The color of the hair is variable, depending upon the country the animal inhabits; the usual color is light gray. In America the wolf is becoming extinct, but in Europe it is still found in considerable numbers in many parts of Sweden, Russia and Poland. The wolf of India is considered a distinct species. It has a reddish color.

Woodpecker (*Picidae*). A forest bird adapted to clinging to trees and making holes in the wood with its beak. The tongue is elongated backward, to enable the bird to remove insects from the holes bored. The woodpecker generally has contrasted colors: green and yellow, or black and white. Its head is usually tinted red. The woodpecker is found in almost every part of the globe.

Wren (*Troglodytidae*). A group of small dull-colored birds having slender, slightly curved, pointed bills. The wings are short and rounded, and the tail is short and carried erect. Most of the wrens live on or near the ground, feeding on insects and worms which they find among the low brushes. The European wren (*Nannus troglodytes*) is abundant in northern Europe where it frequents gardens, hedges and thickets. The North American species are numerous. The common house wren (*Troglodytes aëdon*) is abundant over the eastern part of our country, often living in houses built for them. The song of the wren is very melodious. The male is a bold creature, often attacking birds much larger than itself, such as the bluebird and swallow.

Yak (*Bos grunniens*). An ox-like animal native to the high regions of Tibet. Its neck is longer in proportion to the body than in any other ox-like animals; its body, especially on the lower parts, is covered with long hair.

Zebra (*Equidae*). A name often given to all striped members of the family *Equidae*, but properly restricted to mean but a single species, *Equus zebra*. All resemble the ass more than the horse. Zebras are light and graceful, with slender limbs. The ground color is creamy, with the head, neck, body and legs striped with black. They are almost untamable, although they have been driven in harness.

COMPARING FOOD VALUES AT A GLANCE

The graph at top left shows the percentage of protein (red), fat (yellow), carbohydrate (blue), water (green) and mineral (purple). Milk is an almost perfectly balanced food. Compare the band representing milk with those of the other foods.

The amount of heat necessary to raise the temperature of 1 liter of water from 0° to 100° Centigrade (from freezing to boiling) is 100 calories. Each portion around the vessel is the equivalent of 100 calories.

At bottom left are twin chicks; the sturdy one had a vitamin diet, while the other had no vitamins. The three squares indicate diet requirements: in iron (red), in calcium (blue); in phosphorus (yellow). The three rectangles show how cooking breaks down the indigestible capsules which enclose the starch granules in our starchy foods: the first rectangle shows with no cooking; the next, with a little cooking; the third, when thoroughly cooked. At lower right is depicted the balanced meal amid pleasant surroundings.

BOOK XII

HYGIENE

The Wonderful One-hoss Shay

MAN is mortal and the years of his life are numbered. In Biblical times David set threescore years and ten as the span of man's life. It is true that only a very few live this allotted period. Many die in infancy and in the years of early youth; others live on through the decades. Of these, some are healthy and strong. They drink from the cup of life in good spirit, with zest for the day's labor and joy for the thrill of living. Others are tired and ailing; the weeks and months are marked off one from another by illnesses that steal the strength and weaken the spirit and the body.

Through the centuries men have labored to understand the mysteries of the living organism. They have come to understand its structure, how the parts are related and how they function. *Anatomy* (the study of structure) and *physiology* (the study of function) have become great sciences. It has not seemed sufficient, however, to understand only this much. Other curious men have questioned Nature about disease, learned how it is caused and, in many instances, how it may be cured. They have not ceased their labors. In modern times they have begun to understand how disease may be prevented. It has come to pass that *hygiene* (the study of health) has risen to the position of a medical science. As hygienic knowledge has increased, hygienic teachings have been more and more effectively practiced. The consequence, especially in the last fifty years, has been the control of many insanitary practices and conditions, the prevention of a considerable fraction of premature death and the elimination of some of the illness that saps the strength of the people.

The Span of Life. Not many years ago, a newborn babe had an even chance of living about thirty years. So great have been the improvements in the ways of living that today in the United States the chances are even that the newborn may live between fifty and sixty years. Twoscore years and ten have already been attained and there is hope for further increases. Perhaps it is true, as has been claimed, that David spoke in a moment of pessimism and that the true span of life is that recorded in the sixth chapter of Genesis:

> And the Lord said, my spirit shall not always strive with man, for that he also is flesh; yet his days shall be an hundred and twenty years.

It is not sufficient that we shall live long. It is far more important that we should be healthy while we live. The physician's ideal of healthy living can be read into the charming poem of Oliver Wendell Holmes, *The Deacon's Masterpiece* or *The Wonderful One-hoss Shay*. You may remember how the deacon built his masterpiece,

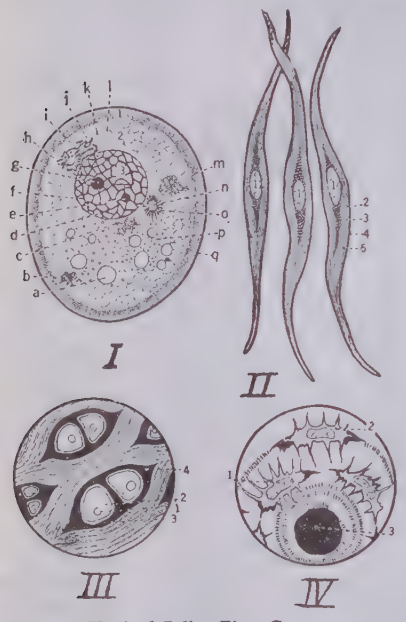
> . . . the wonderful one-hoss shay
> That was built in such a logical way
> It ran a hundred years to a day.

He had reasoned that chaises break down, but never wear out; he had built his with each part as strong as the rest. And on the hundredth anniversary, when a later owner was out for a drive, something happened:

> . . . What do you think the parson found,
> When he got up and stared around?
> The poor old chaise in a heap or mound,
> As if it had been to the mill and ground!
> You see, of course, if you're not a dunce,
> How it went to pieces all at once—
> All at once, and nothing first—
> Just as bubbles do when they burst.

The deacon's chaise, whose every part was as strong as every other and which went to pieces all at once, nothing first, may be symbolic of the perfect human body. The end should come not through sickness, not through accident, not through breakdown, but through normal wearing out and decay. And as bubbles before they burst, our bodies should be perfect, whole and hearty until the final breath is drawn. How far the realization of this ideal is from the actual fact we know only too well.

In the pages that follow is set forth the story of the human body, how it is constructed, how it operates and how it should be cared for so that it may grow correctly and function efficiently. It is not necessary to learn all the details that are described. It is sufficient to understand the main facts. The laws of personal and community hygiene can then be utilized, not as rules of thumb, but as guiding principles for the routine of living.



THE STRUCTURE OF THE BODY

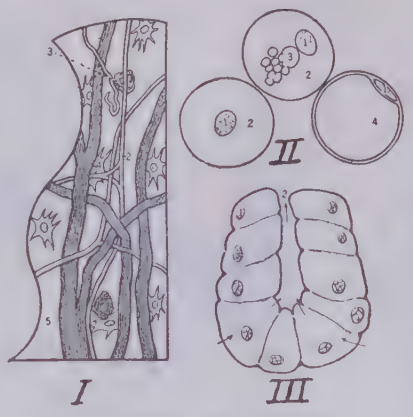
To understand the relatively simple rules of healthy living, it is essential to know the fundamental facts about the structure of the human body and how it works. In the following discussions the elements of anatomy and physiology are presented only in sufficient detail to indicate the reasons for the rules of hygiene. We are fortunate in being privileged to have our descriptions illustrated by diagrams prepared by the Denoyer-Geppert Company of Chicago after the splendid, colored drawings of the Winslow *Health and Hygiene Charts* which they prepare and publish for the teaching of hygiene. Unless otherwise specified, the figures have been taken from their *Teacher's Manual*, prepared for use in connection with these charts.

Cells, Tissues, Organs, Systems. It is well known to most persons that the body is made of smaller parts just as a house is made of bricks, boards, beams, nails and other essential things. The smallest living unit in any living body is the *cell*. There are many kinds of cells, differing in form as they do in function. Cells of the same kind usually occur combined in masses which are called *tissues*; two or more kinds of tissues in functional combinations make up an *organ*; and organs in functional organizations comprise *systems*. For this reason we may speak of the body as a complex organization of systems whose operations are coördinated for the growth, maintenance and reproduction of

the individual. The plan to be followed in this book in considering the hygiene of the body depends upon understanding first, the units of structure (cells, tissues and organs), later the organization and operation of the several systems, and finally the work of the body as a whole.

Types of Cells. In order to illustrate the characteristics common to all cells, a drawing is introduced to represent a generalized cell. It is drawn like no particular cell and, although it does not contain all details, it illustrates how complex the simplest unit of living matter is when its finer details are considered. Muscle cells of the "smooth" kind occur in those muscles that are not under voluntary

Typical Cells—First Group



I. Generalized cell, showing parts common to most cells, 1. Exoplasm, (m) Microsomes, (q) Cell membrane; 2. Endoplasm, (a) Fluid vacuole or oil drop, (b) Foreign inclusions [metaplasm, pigment etc.], (c) Chromidia, (i) Mitochondria or plastosomes, (k) Spongioplasm, (l) Hyaloplasm.

II. Smooth muscle cells; 1. Nucleus; 2. Protoplasm, finely granular interfibrillar sarcoplasm; 3. Sarcoplasm, coarsely granular; 4. Sarcolemma; 5. Myofibrils.

III. Fibrocartilage (with groups of two daughter cartilage cells); 1. Nucleus of daughter cell; 2. Cytoplasm of daughter cell; 3. Capsule of daughter cell; 4. Cartilage matrix.

IV. Bone cell; 1. Nucleus; 2. Bone corpuscle; 3. Haversian canal.

control and those of the "striated" kind occur in muscles that are under control of the will. The body is built upon a framework of bony structures (the skeleton), the living parts of which are the bone cells. They secrete the material which becomes impregnated with mineral matter that is chiefly calcium phosphate and which makes up about two-thirds of the weight of the bone. Nourishment reaches the bone cell through blood that flows in capillaries located in special pores in the bones (the Haversian canals). Bone is not made in the body as such but is formed by mineralization of the softer cartilage tissues of which the cartilage cells are the essential parts. Many groups of tissues are held together by a special kind called "connective" tissue. When an excess of fat is stored in this tissue, it becomes transformed into "fat" (adipose) tissue which is characterized by fat cells. Body fluids and secretions, such as the lachrymal fluid that bathes the eyes, the gastric juice of the stomach, the saliva, and the sweat on the skin are all prod-

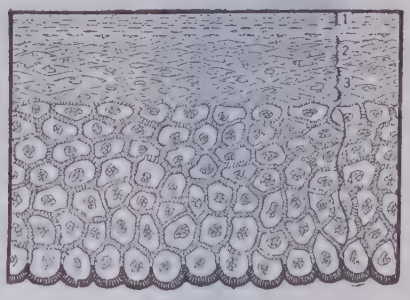
Typical Cells—Second Group

I. Connective Tissue; 1. Collagenous fibers; 2. Elastic fiber; 3. Mast cells; 4. Lamellar cell, fibroblast; 5. Intercellular substance.

II. Adipose or fat cells; 1. Nucleus; 2. Cytoplasm; 3. Fat globules; 4. Fused globules displacing cytoplasm.

III. Gland (simple tubular) cells arranged to line a duct. Substances reach the cells from the blood and the specific secretions of the cells are excreted into the duct. 1. Nucleus of gland cell; 2. Duct.

ucts of variously specialized "gland" cells. Commonly these are arranged in such a way that the fluids that come to the cells from the blood are changed by them and the characteristic secretion of the gland cells is passed out through a canal or duct of which the cells themselves form the lining. The control of the several parts of the body so that they function in an harmonious manner is accomplished through the chemical composition of the blood and by the nervous system. Of the latter the nerve cell is the basic unit. The central part of such a cell is the neuron. This may be as small as most tissue cells or may



Nerve Cell

1. Nucleus; 2. Dendron or dendrite; 3. Neurofibrils; 4. Chromatophile granules; 5. Nucleolus; 6. Axon; 7. Gemmules; 8. Axon hillock (by which the axon rises from cell body). The dendrons and axons may be very long.

be large enough to be seen with the naked eye. The fine fibers which run out from the neuron (the axons) may extend for several feet to remote parts of the body, to a muscle or other tissue to which the neuron sends or relays stimulations. The dendrons (dendrites) are fine processes or outgrowths from the neuron by means of which it is linked with other neurons.

A Tissue (The Skin). To illustrate how cells are aggregated into tissues the skin may be taken as an example. The lowest layer (*stratum mucosum*) is made up of active, living cells that are nearly cylindrical in shape. These grow and divide, the growth occurring outwards to the (upper) surface, the cells becoming flat and less active until the outermost layer (*stratum corneum*) is reached. At this level the cells are flat, horny and dead, and no nuclei are seen in the cells. These are more or less continually scaling off the surface and being replaced by cells from below.

Skin Tissue

An example of cells aggregated into a tissue; 1. Stratum corneum; 2. Stratum lucidum; 3. Stratum granulosum; 4. Stratum mucosum.

Such color as the skin has is principally due to the pigment that is produced by the cells of the lowest layer of the epidermis.

THE SYSTEMS OF THE BODY AND THEIR HYGIENE

The Skeletal System. The body is an aggregation of systems, organs and cavities built around a bony framework or *skeleton*. This consists of 206 bones, some of which are fused or joined firmly together; others are attached by joints which permit free or limited motions. The general scheme of the skeletal system is a main, upright, supporting series of bones—the spinal column—on top of which is fastened the skull and its appendages; a little below is the shoulder girdle, and at the bottom the pelvic girdle. From the front of the shoulder girdle there extends a series of three bones that make up the sternum; and between the back of the spinal column and the front of the sternum run the first ten ribs (costae). The eleventh and twelfth ("floating") ribs do not reach the sternum. This last group of bones (spinal column, ribs and sternum) makes a basket-like structure which contains and protects from injury many of the most delicate and vital organs of the body. The arms are joined to the shoulder girdle and the legs to the pelvic girdle.

Joints. The spinal column has an *S* shape which gives it a spring-like, shock-absorbing power that is particularly valuable in the protection of the head and its contents when the body is in motion. The vertebrae (unit bones of the spine) are separated by soft inter-vertebral pads. With the help of the vertebral muscles, the spine may be tilted to one side or the other by the contraction and relaxation of the opposing muscles between the transverse processes.

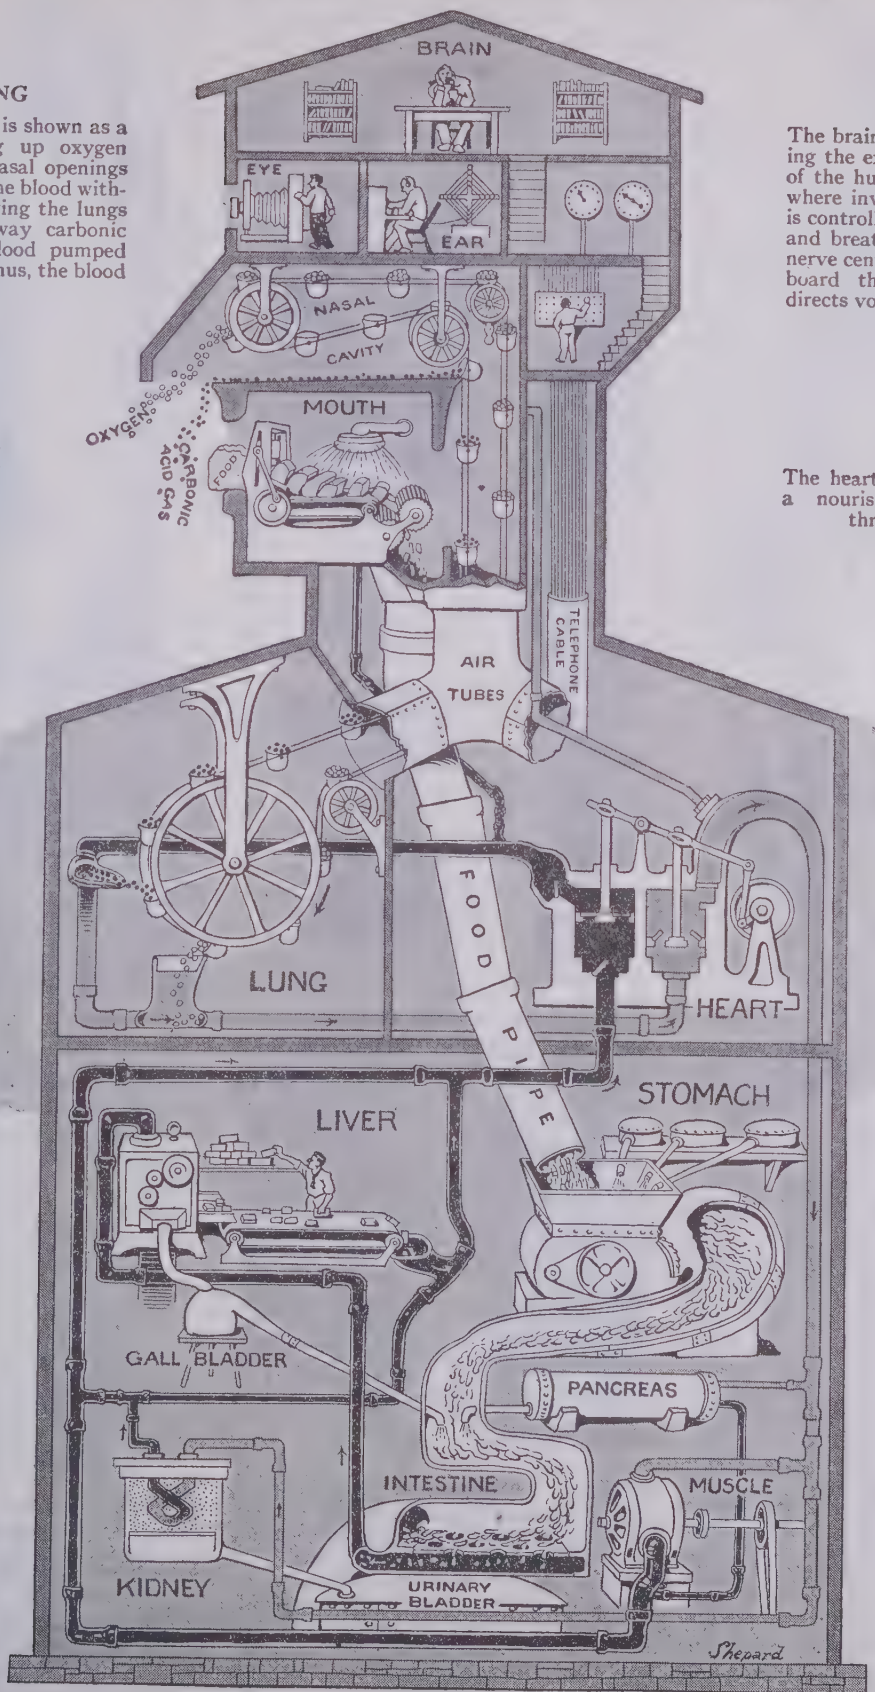
Among the other kinds of bone joints, the "pivot" joint is illustrated in the atlas (first

THE HUMAN FACTORY

BREATHING

The breathing system is shown as a bucket chain picking up oxygen from the air at the nasal openings and emptying it into the blood within the lungs. On leaving the lungs the buckets carry away carbonic acid gas from the blood pumped there by the heart. Thus, the blood is purified

FOOD



Food entering the mouth is shown being cut by a slicer (the front teeth) and then carried on a conveyor (the tongue) to the crusher (the back teeth). During this process of cutting and mashing, the salivary secretions from the mouth are mixed with the food.

LIVER

In the liver, sugar is stored in the form of animal starch (glycogen); wastes and poisons are removed from the blood, and bile is manufactured. The bile is stored in the gall bladder until it is needed in the intestines.

KIDNEYS

The kidneys are filters for the blood; they filter water and many waste products out of the blood, thus producing the urine.

BRAIN

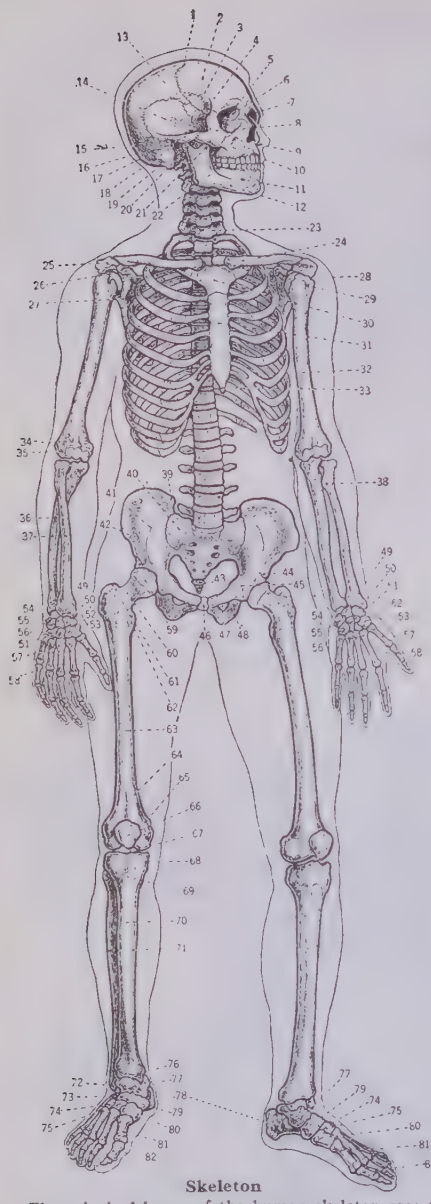
The brain is represented by picturing the executive or directing head of the human factory; a dial room where involuntary muscular action is controlled, such as the heart beat and breathing. The motor (action) nerve center is pictured as a switchboard through which the brain directs voluntary movements of the body.

HEART

The heart is a pump which forces a nourishing stream of blood throughout the body.

STOMACH

The stomach is a mixer and kneader It is here that pepsin and other ferments are mixed with the food.



INTESTINES

From the intestines the blood takes sugar and other digested foods.

MUSCLES

A picture of a motor is shown to indicate the muscles — energy and power. The blood brings to the muscles the fuel and removes the wastes.

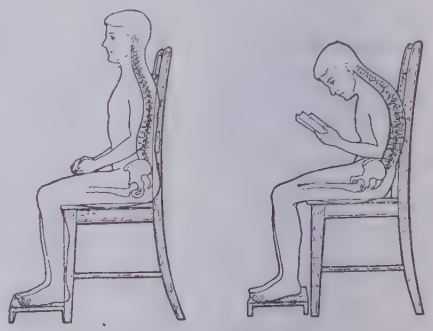
ligaments. A dislocated joint requires prompt attention by a physician or surgeon.

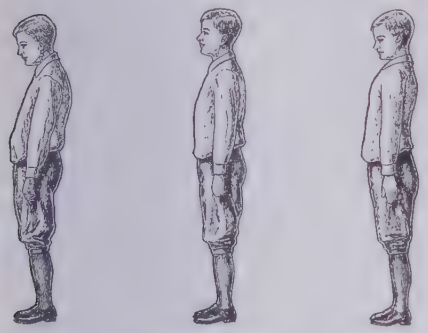


Structure of Bone. The periosteum is a thin layer of tissue which covers the bone. It is the living part of the bone and from it the bone is made. The shafts of the long bones are hollow, so that they are light in weight and yet strong; they are filled with soft marrow. Blood cells are manufactured in the marrow.

Joints

At the left, the ball and socket joint, right hip; at the right, hinge joint, right elbow. Note how the bones are bound together by the ligaments (84-87). To illustrate the structure of a long bone, a flap of periosteum is cut away at 88 and the bone has been split open to show the marrow that fills the hollow shaft. 34. Medial epicondyle of humerus; 35. Lateral epicondyle of humerus; 36. Ulna; 37. Radius; 38. Radial tuberosity; 84. Iliofemoral ligament; 85. Ischiocapsular ligament; 86. Ligamentum teres femoris; 87. Pubocapsular ligament; 88. Periosteum; 89. Compact bone; 90. Marrow; 91. Cancellous tissue with marrow removed; 92. Head of radius; 93. Capitulum of humerus; 94. Trochlea of humerus; 95. Olecranon process of ulna; 96. Coronoid process of ulna; 97. Oblique ligament; 98. Antibrachial interosseous ligament.

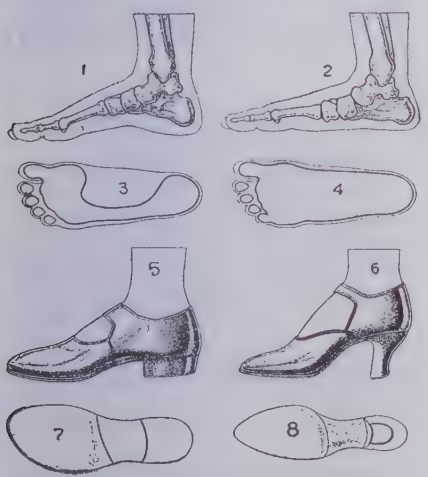
Posture. It is plain that the functions of the skeleton are to serve as a framework for the body, to protect many of the soft parts from injury, to provide the necessary cavities for the lungs and other organs, to pro-



Sitting Posture

At the left is illustrated correct posture. The boy reading shows incorrect posture.

vide strength and opportunities for motion, and to maintain the necessary shock-absorbing systems. It must be clear that good posture, which means the proper management

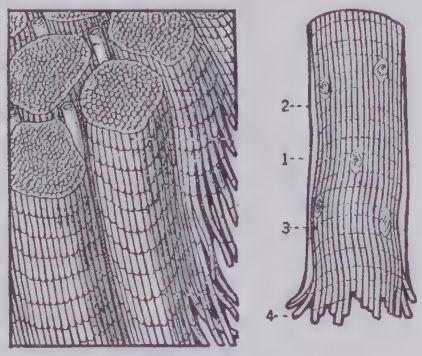


and arrangement of the skeleton, is essential for the proper functioning of the body. "Slumped, twisted or strained posture is not only ungraceful and ugly but may do serious harm to the health by interfering with circulation and cramping the inner organs."(Winslow.) Good sitting and standing postures are very important, particularly for children.

Standing Posture

At the left is shown careless posture; next, correct posture; at the right, exaggerated posture.

The bones of the foot are arranged in a strong, shock-absorbing, springy arch. A broken arch (flat foot) is a serious handicap. Wearing sensible, correct shoes is a good safeguard for the feet. A shoe with a narrow, pointed toe and high heel can do no good and much damage to the foot within it. Flat-foot and other conditions can often be cured by toe and foot exercises and by wearing correct shoes that do not cramp the toes

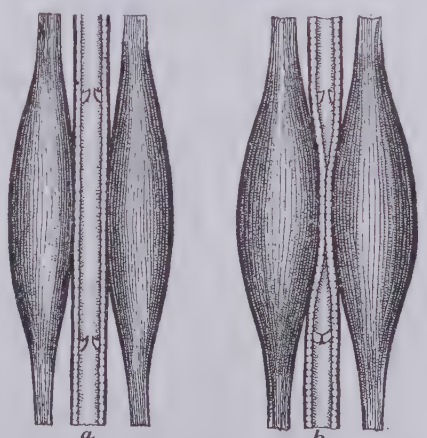


Good and Bad Footwear

1. Bones of normal arch; 2. Bones of fallen arch; 3. Footprint from normal foot; 4. Footprint from flat foot; 5. Healthful type of shoe; 6. Harmful type of shoe; 7. Sole of healthful type of shoe; 8. Sole of harmful type of shoe.

or throw the bones of the foot off their true arch. The exercises recommended for partly or completely correcting fallen arches and strengthening the muscles of the feet are these: repeatedly rise on the toes when standing; place the soles of the feet together when sitting. Another good exercise is to stand on a towel with bare feet and tuck the towel under the feet by gripping it with the toes.

The Muscular System. Approximately one-half of the body weight is in the more than 500 *muscles*, large and small. Some are under control of the will (*voluntary*) and others are not (*involuntary*). Of the former, those which control the movements of the various parts of the body are examples familiar to everyone. Of the latter, the muscles



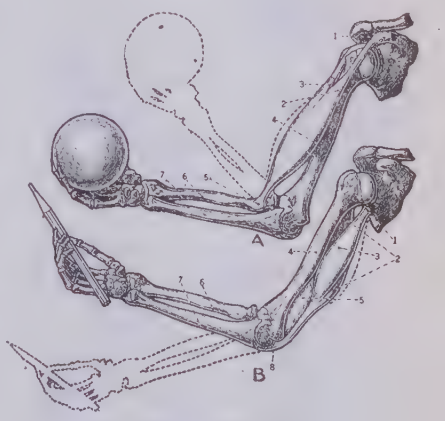
Muscle Cells

At the left, magnified muscle bundles of the kind that are "voluntary" (under control of the will). Note the cross-striations.

At the right, a single muscle cell, much more enlarged. Note that this type of cell has many nuclei (1), a definite wall (2) and many rods (3, 4) which are marked by cross-striations.

of the walls of the intestines and blood vessels, the heart wall and others may be cited. The involuntary as well as the voluntary muscles are always in a state of greater or lesser *tonus* or contraction, complete relaxation being apparently incompatible with the living state. The tonus of the involuntary muscle is controlled by nervous and by chemical stimuli; the tonus of the voluntary muscles is, in addition, controlled by the will.

It has already been seen that smooth (involuntary) muscle cells are simple cells with single nuclei (p. 978). In contrast, the cells



How Contracting Muscles Increase the Flow of Blood Through Veins

Showing, (a) Muscles relaxed, (b) Muscles contracted. The valves in the veins permit the blood to flow only one way—towards the heart.

of voluntary muscles appear to be bundles of rods or fibrils with cross striations and many nuclei. These cells are known as "striated" muscle cells because of the striations or cross markings. Bundles of muscle cells comprise a "muscle bundle." A large muscle, like the biceps, consists of many thousands of cells.

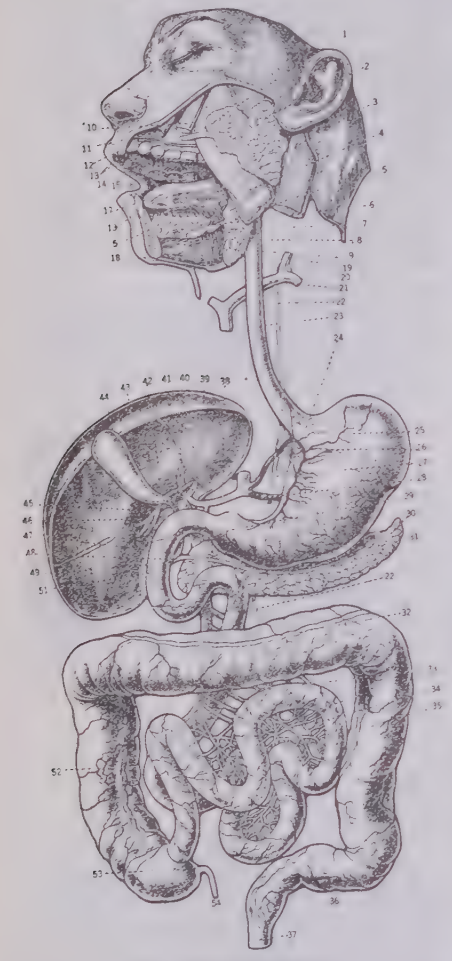
The most obvious function of voluntary muscles is for the purpose of motion of parts of the body. For example, by contracting the biceps, the forearm is raised. To restore the arm to its original position it may be sufficient merely to relax the muscle and permit the arm to fall. More often the result is accomplished by causing another muscle, the triceps, to contract on the other side of the arm. Raising the arm by contraction of the biceps is also accompanied by the simultaneous relaxation of the triceps. Muscles cannot push; they can only pull. For this reason practically all muscles are in pairs or groups that act more or less oppositely. A quiet, resting position of a limb or organ is often the result of the balanced pulls of opposing muscles. It is the balanced action of opposing muscles that makes an upright posture possible.

The heart is really little more than a mass of involuntary muscles that keep contracting and relaxing in a rhythmical fashion. The involuntary muscles in the walls of the stom-

How Muscles Effect Motion

In the upper figure, contraction of the biceps raises the forearm. Muscles can pull, but cannot push. In the lower figure, to lower the arm, the opposing muscles contract and the biceps relaxes.

A. 1. Coracoid process; 2. Biceps (short head); 3. biceps (long head); 4. humerus; 5. radial tuberosity; 6. Radius; 7. Ulna



B. 1. Origin of triceps (long head); 2. Triceps; 3. Triceps; 4. Humerus; 5. Medial head of triceps; 6. Radius; 7. Ulna; 8. Elbow.

ach and intestines contract and relax alternately to churn the contents and, at suitable times, cause the food to move on through the gastro-intestinal tract. Many muscles combine to cause the motions that result in inspiration and expiration. Expiration is normally a passive process. Corsets and tight clothes interfere with breathing and tend to make for shallow respiration.

It is hardly necessary to remark that most muscles are strengthened and enlarged (hypertrophied) by use, and are weakened and reduced (atrophied) by lack of use. Exercise, in moderation, serves to keep the muscles in a healthy state and commonly also aids directly in the state of other organs and tissues. The flow of blood in the veins is considerably accelerated by the contraction of muscles, so that muscular exercise aids the blood supply of many tissues. On the other

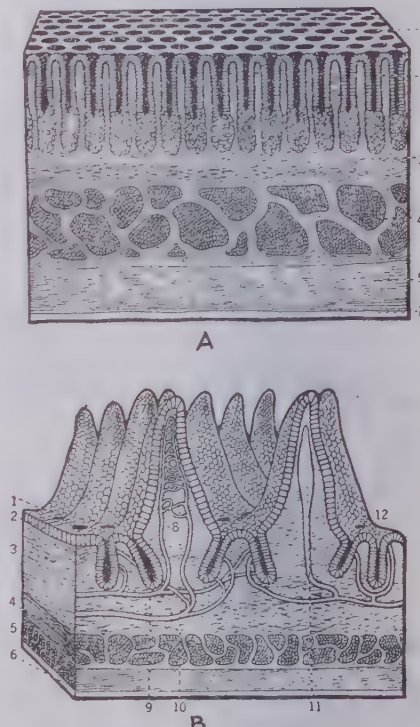
hand, it is not ordinarily advantageous to exercise vigorously directly after a meal, probably because blood which is needed in the digestive organs is thereby diverted to other parts.

Regular, moderate exercise every day will help keep the body in a healthy state. Vigorous exercise should not be prolonged and should be followed by rest.

The Digestive System

The principal parts of the digestive system. The small intestine (33) is drawn considerably shortened so that it will not obscure other parts in the drawing. 1. Parotid duct; 2. Parotid gland; 3. Sternocleidomastoid muscle; 4. Masseter; 5. Mandible; 6. Sublingual gland; 7. Submaxillary gland; 8. Hyoglossus muscle; 9. Genioglossus muscle; 10. Zygomatic muscle; 11. Caninus muscle; 12. Orbicularis oris; 13. Incisors; 14. Canine (cuspid); 15. Premolars (bicuspid); 16. Molars; 17. Tongue; 18. Geniohyoid muscle; 19. Left jugular vein; 20. Left subclavian vein; 21. Left innominate vein; 22. Thoracic duct; 23. Esophagus; 24. Cardiac orifice of stomach; 25. Fundus of stomach; 26. Right gastric artery; 27. Celiac artery; 28. Lienal artery; 29. Pyloric orifice of stomach; 30. Pancreas; 31. Portal vein; 32. Transverse colon; 33. Small intestine; 34. Lacteals; 35. Descending colon; 36. Sigmoid flexure of colon; 37. Rectum; 38. Hepatic artery; 39. Liver, left lobe; 40. Hepatic duct; 41. Round ligament; 42. Cystic duct; 43. Quadrate lobe; 44. Gall bladder; 45. Portal vein, left branch; 46. Portal vein, right branch; 47. Coronary ligament; 48. Common bile duct; 49. Pancreatic duct; 51. Duodenum; 52. Ascending colon; 53. Caecum; 54. Vermiform appendix.

The Digestive System. Every living cell is continually using up energy in order merely to remain live. It must, therefore, have a continuous food supply. In addition, the living cell is breaking down and repairing itself, growing and reproducing itself. All of the constituents that it needs to make its own substance are supplied in food that is ingested by the organism of which the cells are the ultimate living units. But the foods that are eaten cannot be utilized directly by the cells: solids must be converted to liquid form, and even liquids must generally be changed chemically so that they can be absorbed through the membranes that line the stomach and intestines in order that they shall reach the circulating blood and lymph that will carry them to the tissue cells. The organs of digestion are those which accomplish the marvelous transformations of foods so that they are prepared for the blood and lymph.



The *alimentary tract* is essentially a long and complicated tube into which food enters (at the mouth), in which it is acted upon in various ways, and from which the digested parts are absorbed and the undigested fractions excreted at the end of the tube (the rectum). The principal parts of the alimentary tract and the functions performed in each are indicated in the following sequence:

Mouth. Food is broken up by the teeth and the tongue in chewing and by the enzymes or ferments (substances secreted by glands and which break up food molecules) contained in the saliva secreted into the mouth by the salivary glands. These enzymes act particularly upon starches and starchy foods.

Esophagus. When food is swallowed it passes from the mouth into the esophagus (which is a long, muscular tube) and thence into the stomach.

Stomach. In the stomach the food is further broken up mechanically by the churning action brought about in this organ by the contractions of the muscle layers in its walls, and chemically by the digestive (gastric) juice secreted by many glands in the walls of the stomach. The gastric juice contains hydrochloric acid and two important enzymes, pepsin and rennin, both of which act on proteins. Rennin clots milk and is especially important in the baby's digestion. After digestion in the stomach the partly changed food, now in a liquid state (chyme), is passed on by waves of muscular contractions (called "peristaltic waves") into the small intestine by passage through the pylorus, the opening of the stomach. The pylorus is circled by strong muscles which, when contracted, keep food in the stomach in spite of strong contractions of that organ.

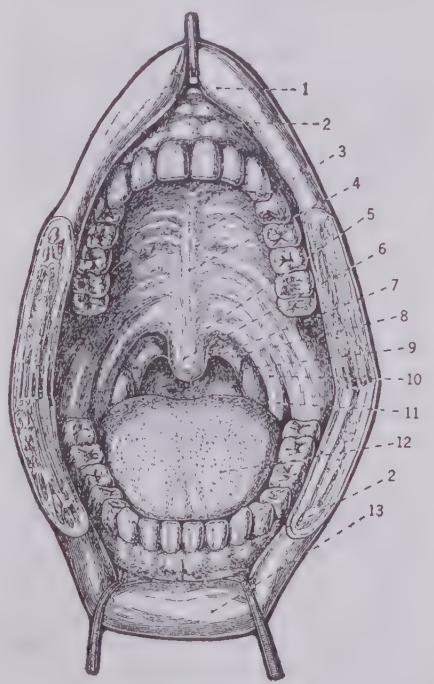
Small Intestine. This is a coiled tube, about twenty feet long, which is called the "small" intestine because of its narrow diameter as contrasted with the broader but shorter "large" intestine. In the first part of the small intestine (the duodenum) the partly digested, liquid chyme is mixed with three very powerful digestive juices which are secreted from the pancreas (pancreatic juice) from the liver (bile) and from glands in the walls of the intestine (*succus entericus*). The pancreatic juice, admitted to the duodenum through the pancreatic duct, contains enzymes that attack proteins, starches and fats. The bile, which is manufactured by the liver and stored in the gall bladder until needed and which enters through the bile duct, probably acts in the preparation of fats for digestion by the lipase (fat-digesting enzyme) of the pancreatic juice. It probably also aids the absorption of the products of digestion. The secretion of the intestinal glands is especially powerful in aiding protein and starch digestion. While digestion is going on the food is being passed along by successive peristaltic waves into the next part of the small intestine, the jejunum, and finally into the last section, the ileum. As it goes, the final products of digestion, now soluble and absorbable, pass through the walls of the intestine. The products of protein and starch digestion are absorbed through the veins and carried by the blood to the liver. The products of fat digestion are taken into the small lymph vessels (*lacteals*), thence in the lymph they are carried through the thoracic duct into the blood by way of the left subclavian vein. In the liver, much of the digested sugar and starch that is not needed by the body at once is stored as *glycogen*. Fat may be stored in the liver or in fat cells in many connective tissues of the body. By the time the intestinal contents have reached the end of the ileum, most of the products of digestion have been absorbed. The unabsorbed and undigested residue is then pushed by peristalsis into the large intestine.

Stomach and Small Intestine in Section

Drawings of sections through (A) the stomach and (B) the small intestine. The glands are very numerous in both. In B their occurrence as finger-like projections enormously increases the surface available for the absorption of the products of digestion. 1. Surface of mucous membrane showing gland openings; 2. Gland layer; 3. Areolar layer; 4. Transverse muscle layer; 5. Longitudinal muscle layer; 6. Peritoneal coat; 7. Surface of villus; 8. Section of villus; 9. Vein; 10. Artery; 11. Lacteal; 12. Gland.

Large Intestine. As the intestinal contents enter the first part of the large intestine (the ascending colon) through the ileo-cecal valve, they pass a small pouch-like appendage (the appendix) which is of no particular interest

except that when it becomes infected and inflamed (appendicitis) it must usually be removed surgically. Digestion has been practically completed in the small intestine. In the colon (large intestine) the water must be absorbed and the semi-dry residue stored. These functions are accomplished as the material is pushed along the ascending, transverse and descending colons. From the rectum the masses of waste (feces) are discharged through the anus.



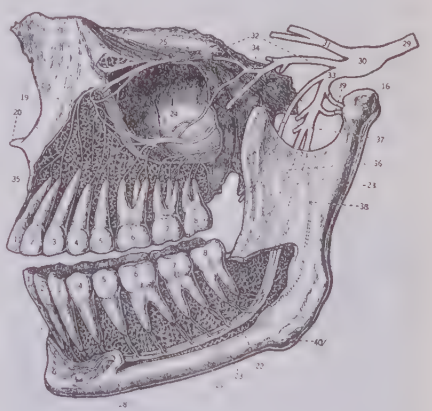
Bacteria in the Digestive Tract. It must be kept in mind that food for man is also quite commonly food for bacteria. Also, there are bacteria in and upon practically everything (see p. 996). Bacterial growth will go on in the foods that are ingested, especially because mixing with water and the warmth of the body stimulate the activities of the microorganisms. There is no significant bacterial action on foods in the upper parts of the alimentary tract because the ingested food material is in the mouth and esophagus for moments only. In the stomach, many bacteria are killed and others are inhibited by the hydrochloric acid of the gastric juice. In the small and large intestines, particularly the latter, the restraints on bacteria are lost, and extensive multiplication occurs so that the contents of the colon come to contain many thousands of millions of bacteria. These are primarily harmless; but if the contents of the colon are not evacuated regularly (that is, if constipation occurs) the products of microbic action may be absorbed and give rise to *auto-intoxication* (self poisoning), due to the injurious effects of these products upon the tissues of the body. Some of the effects of constipation are probably due to the "lazy" and "full" condition of the intestines. It must be emphasized that individuals vary with respect to the frequency of bowel movements. One-a-day is normal for most people; two-a-day or one-in-two-days may be normal for others. Cathartics should not be used except on rare occasions unless prescribed by a physician. The chief aim of drinking *acidophilus* (milk) is to implant in the colon types of bacteria that are themselves *aciduric* and that will hold in check *putrefactive* kinds. Overeating, lack of exercise, and insufficient roughage in the diet are the commonest causes of simple constipation.

Special Problems of the Mouth and Its Hygiene. Digestion may be said to begin in the mouth with the process of chewing food, because chewing prepares food so that the digestive juices may act upon a pulp instead of upon large, solid or semi-solid masses.

Teeth and Dental Hygiene. The newborn baby does not have visible teeth although they have already been partly formed and are in the gums preparing to complete their development and erupt. For the proper formation of a baby's teeth, good, fresh milk is necessary, mother's milk in preference to cows' milk. About six months after birth the teeth begin to come through the gums. These first teeth will last between six and twelve years and then fall out. They are the "milk" or "temporary" or "deciduous" teeth. They are replaced by the permanent teeth which form beneath them and force them out. When the milk teeth become loose they should be pulled out to permit the permanent teeth to erupt straight.

Many of the lower animals (carnivores) subsist on meat and have sharp, pointed teeth that are effective for tearing; others (graminivores, herbivores) live on grains and have flat teeth that are effective for grinding. Man lives on a mixed diet and possesses both types of teeth. A typical set of permanent teeth consists of four of each of the following (two in each jaw): (1) Central incisors, (2) Lateral incisors, (3) Canines or cuspids, (4) First premolars or bicuspids, (5) Second premolars or bicuspids, (6) First molars, (7) Second molars, (8) Third molars or wisdom teeth. These grade from the first, which are sharp and chisel-edged, to the last, which are flat.

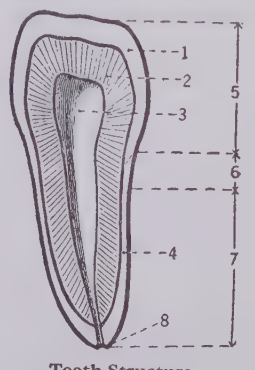
The first of the permanent teeth to appear are the first molars, usually in the sixth year.



The Mouth

1. Upper lip; 2. Gums; 3. Hard palate; 4. Raphe; 5. Soft palate; 6. Uvula; 7. Pharynx; 8. Pharyngopalatine arch; 9. Palatine tonsil; 10. Glossopalatine arch; 11. Vallate papillae; 12. Fungiform papillae; 13. Lower lip.

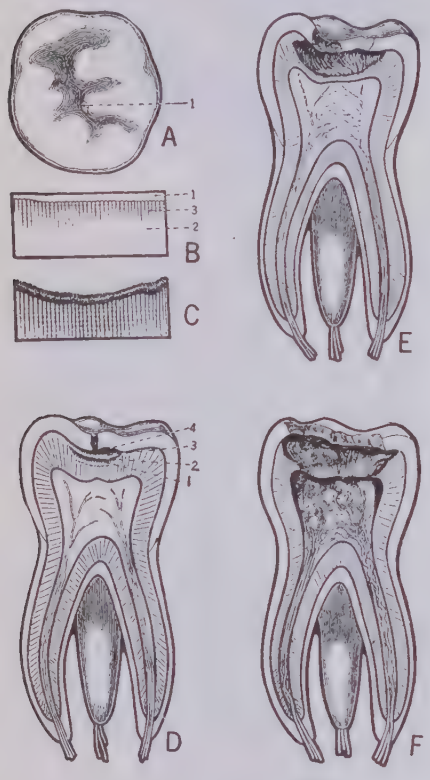
These are the largest of the teeth and are doubly important because they must serve as the chief teeth while the temporary teeth are being replaced. Their health and position therefore largely determine the position of the permanent teeth which follow them. Soon after the seventh year the central incisors appear, and at approximately yearly intervals the lateral incisors, the first and second premolars, the canines and the second molars (after the twelfth year) and finally the third molars (after the seventeenth year).



The Structure of a Tooth. Each tooth may be considered to have three parts: (1) the "crown" which is visible above the gums, (2) the "neck" between the crown and (3) the "root" which is lodged in the bone of the jaw. The outer layer of the crown is an extremely hard substance (*enamel*). On the neck and root the equivalent of this is a moderately hard layer (*cementum*). Beneath the hard outer layer is a thicker layer of softer material (*dentine*) around the central or pulp cavity in which the nerve and blood vessels are contained.

The Teeth

Showing the teeth and their nerve supply. 1. Central incisor; 2. Lateral incisor; 3. Canine or cuspid; 4. First premolar or bicuspid; 5. Second premolar or bicuspid; 6. First molar; 7. Second molar; 8. Third molar or wisdom tooth; 16. Condyle of mandible; 19. Maxilla; 20. Anterior nasal spine; 21. Inferior dental vein; 22. Inferior dental artery; 23. Inferior dental nerve; 24. Antrum of Highmore (maxillary sinus); 25. Floor of orbit; 26. External pterygoid lamina; 27. Tuberosity of maxilla; 28. Mental foramen; 29. Fifth cranial or trigeminal nerve; 30. Gasserian ganglion; 31. Ophthalmic division of the fifth nerve; 32. Maxillary division of the fifth nerve; 33. Mandibular division of the fifth nerve; 34. Posterior superior dental branches; 35. Aveolar plexus; 36. Lingula nerve; 37. Buccal nerve; 38. Mylohyoid nerve; 39. Auriculotemporal nerve; 40. Angle of mandible.



Decay of the Teeth. Dental caries, or tooth decay, is the most important danger to teeth. This usually starts in some tiny flaw or area of injury in the enamel. A little food and some bacteria collect, the bacteria develop and form acids which attack the enamel. The injured area becomes more extensive, reaches the dentine and eventually the pulp cavity. Here the bacteria and the products of decay may reach the nerve and set up excruciating pain. They may reach the blood vessels, enter them and be carried in the blood to other parts of the body. A decayed tooth is frequently the "focus" of infection for many parts of the body, often resulting in serious disease.

Tooth Structure

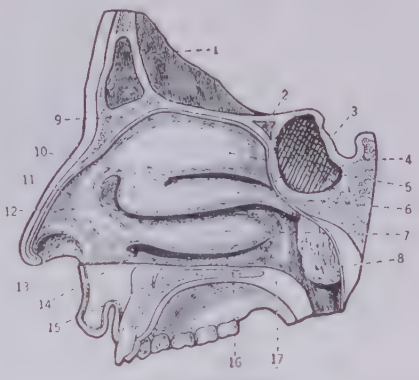
Section of an incisor to show the structure of a tooth. 1. Enamel composed of enamel prisms; 2. Dentine; 3. Pulp cavity; 4. Cementum; 5. Crown; 6. Neck; 7. Root; 8. Apex.

Although it is sometimes said that "A clean tooth never decays," this is not entirely true. It is true that brushing the teeth once, twice or three times a day may help to control infection of the teeth, but this alone will not insure their health. The mechanical action of brushing is of more importance than the kind of dentifrice used. The evidence available at this time (1931) indicates that diet is, if anything, more important than cleanliness in the care of the teeth. An adequate diet, in which plentiful use of milk, and orange juice is most important, is the best insurance for sound teeth. A well balanced diet of the mother before the baby is born, good diet for the baby and for the growing child provide the basis for good dentition. In addition, cleanliness of the teeth and periodic examination by the dentist, at least once and preferably more often each year, should insure healthy teeth. With frequent and regular examinations the dentist can detect early flaws in the teeth. These can be repaired by simple and often painless treatment so that more serious damage is not likely to occur. Decayed and abscessed teeth if beyond repair should be removed without delay.

The Story of a Tooth's Decay

A. The free surface of a molar showing a lustreless white spot (1) and roughening of the enamel.

B. A section of the dental enamel; 1. Film; 2. Enamel prisms; 3. Film invading interprismatic spaces.

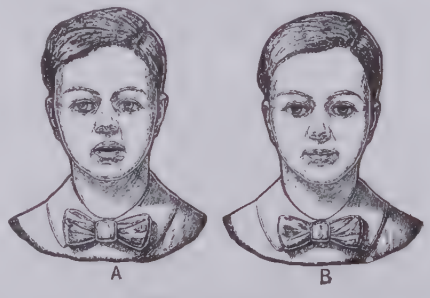


C. Further decay of the enamel and formation of a furry layer.

D. Decay (caries) progresses and then advances more rapidly after reaching the dentine. 1. Transparent layer; 2. Opaque layer; 3. Layer of softening; 4. Layer of disintegration.

E. More extensive advance of caries undercutting enamel approaching dental pulp.

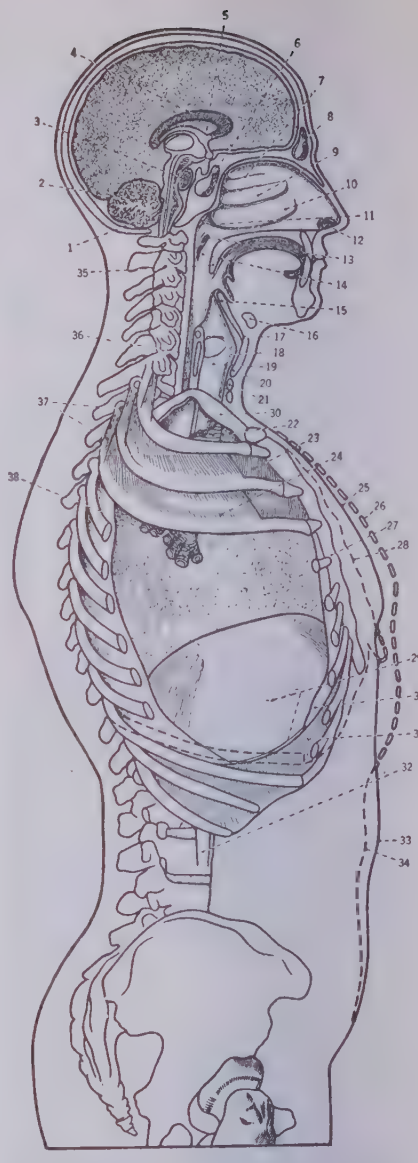
F. The enamel crown has collapsed. The pulp is exposed, inflamed and painful. The nerve must be extracted and the tooth repaired.



The Tonsils. On each side of the back of the throat is a structure of lymphoid tissue called the *tonsil* or *palatine tonsil.* It is a complex structure with deep crypts which open into the throat. Bacteria frequently gain entrance into these crypts and infect them. Tonsils which have become infected may serve as a reservoir of bacteria which may repeatedly infect the adjacent tissues or may gain entrance to the blood vessels, be carried by the blood to other parts of the body and set up secondary infections. Diseased tonsils can and should be removed by a simple, surgical operation (*tonsillectomy*).

The Nasal Cavity

A view of the nasal cavity, showing particularly the position of enlarged adenoid tisse (8). 1. Frontal sinus; 2. Posterior ethmoidal cells; 3. Sphenoidal sinus; 4. Sphenoid bone; 5. Superior concha; 6. Middle concha; 7. Inferior concha; 8. Enlarged adenoid tissue; 9. Frontal bone; 10. Superior nasal meatus; 11. Middle nasal meatus; 12. Atrium; 13. Vestibule; 14. Inferior nasal meatus; 15. Incisive canal; 16. Hard palate; 17. Soft palate.



Adenoids. Above and behind the soft palate is a pair of small structures called the *pharyngeal tonsils.* In young children there is frequently a growth on each called the *adenoid.* Adenoid growths obstruct the air passages between the nasal cavities and the mouth so that the child is compelled to breathe through the mouth instead of the nose. This condition is unhygenic, because in cold weather the air taken into the lungs has not been warmed, moistened and filtered as it should be by passage through the nose and over the surfaces of the turbinates and other bony structures which are covered by mucous membranes. Repeated and chronic colds and other ailments frequently result. Another serious damage is the consequence of adenoids. Continued mouth breathing places an unusual strain on the muscles of the face and jaws and tends to cause the young bones to grow in somewhat abnormal ways. The roof of the mouth tends to develop in a high arch so that the teeth occupy irregular positions and are crowded out of their natural sites. The face shows a stupid and strained expression. The adenoids may obstruct the

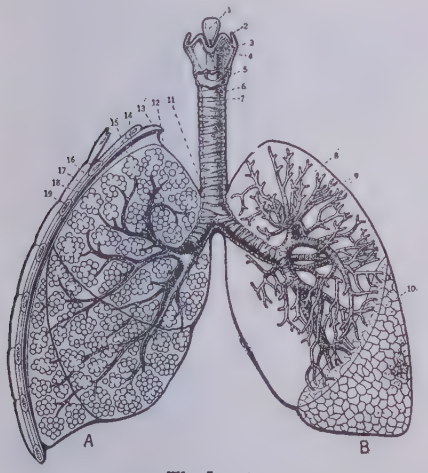
The Respiratory System (lungs omitted)



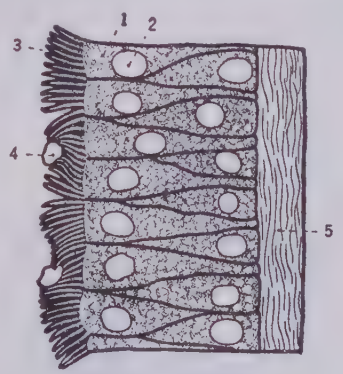
The principal parts of the respiratory system except the lungs which have been omitted.

Note changes in position of parts at inspiration and expiration. 1. Medulla oblongata, center of respiratory control; 2. Cerebellum; 3. Pons; 4. Corpus callosum; 5. Septum pellucidum; 6. Sphenoidal sinus; 7. Superior nasal concha; 8. Frontal sinus; 9. Middle concha; 10. Inferior concha; 11. Choana, posterior opening of nasal cavity; 12. Vestibule of nose; 13. Orifice of auditory (Eustachian) tube; 14. Pharynx; 15. Epiglottis; 16. Hyoid bone; 17. False vocal cord; 18. True vocal cord; 19. Larynx; 20. Thyroid cartilage; 21. Cricoid cartilage; 22. Trachea; 23. Internal intercostal muscles; 24. External intercostal muscles; 25. Outline of thorax at exhalation; 26. Outline of thorax at inhalation; 27. Sternum at exhalation; 28. Sternum at inhalation; 29. Pleura reflected over diaphragm; 30. Pleura; 31. Diaphragm; 32. Tendon of origin of diaphragm; 33. Abdominal wall at exhalation; 34. Abdominal wall at inhalation; 35. Uvula; 36. Esophagus; 37. Levatores costarum muscles; 38. Bronchi.

openings of the Eustachian canal and seriously affect hearing. Adenoid tissue, like all lymphoid tissue in the body, tends to become smaller with age. Unfortunately, the adenoids may do such considerable damage in the years during which they are large that it is far wiser to have them removed by a simple, surgical operation than to wait for the effects of time.

Respiratory System. The essential processes by which living things obtain energy are chemical changes of food substances and reactions with oxygen. The element oxygen is just as important for life as food itself. To supply oxygen regularly and in sufficient quantities to all the tissues, the body utilizes an exquisitively adjusted, complex mechanism in which the organs of the muscular, respiratory, circulatory, nervous and excretory systems all play interrelated rôles. The end effect is that a supply of fresh air is drawn into the lungs on the average about twenty times a minute. When resting quietly or sleeping, the respiratory rate may be as low as sixteen per minute; when exercising, it becomes considerably increased. In each condition the amount of oxygen supplied is adjusted to the needs of the body.

Respiration. Air (which is one-fifth oxygen) enters through the nose or mouth, passes through the *pharynx* and *larynx* into the *trachea* and thence into the *bronchi* and *lungs*. The motions of the air, when it is drawn in



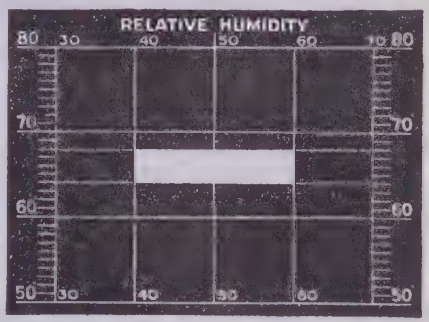
The Lungs

The larynx (which houses the vocal cords), trachea and lungs. At A the right lung is shown in full section; at B, part has been removed from the left lung to show how the bronchi subdivide in tree-like fashion into finer and finer branches (bronchioles, 9). 1. Epiglottis; 2. Superior horn of thyroid cartilage; 3. Thyroid cartilage; 4. Thyroid notch; 5. Cricoid cartilage; 6. Cartilaginous rings of trachea; 7. Membranous tube of trachea; 8. Left bronchus; 9. Bronchioles; 10. Section of lung tissue; 11. Bifurcation of trachea; 12. Section of right bronchus; 13. Pleura; 14. Infundibulum; 15. Alveolus; 16. Serratus anterior muscle; 17. External intercostal muscle; 18. Internal intercostal muscle; 19. Rib.

(*inspiration*) or out (*expiration*), are due to enlargement or reduction in the volume of the chest. In producing these changes the lungs are normally passive. In inspiration the chest is raised and lowered, and its internal capacity is altered by movements of the ribs and the diaphragm (the muscle sheet that makes the floor of the chest cavity). As the chest (thoracic) cavity changes in size, the lungs change similarly. As the thoracic cavity is enlarged, the lungs tend to follow the chest wall, they bellow out and air is drawn into them; as the cavity is reduced, the lungs are compressed and air is expired.

Lungs. The lung itself is merely an extremely convoluted and pouched membranous sac, so that in its minutest parts it is made up of many sacs in which the surfaces are in intimate contact with the air they enclose. In the membranous walls of the lung, down to the finest pouches and sacs (*infundibula* and *alveoli*), there is a rich supply of blood vessels. The consequence is that oxygen from the air in the sacs has only a short path to follow in diffusing through the lining membranes in order to reach the blood; and carbon dioxide, a waste product in the blood, can diffuse out and be expelled with each expiration of air.

Rate of Respiration. The rate of respiration is, in part, under voluntary control. It is also under involuntary control. When there is need for respiration, to supply oxygen and remove carbon dioxide, the accumulated carbon dioxide causes a slightly



Epithelial Cells of Air Passages

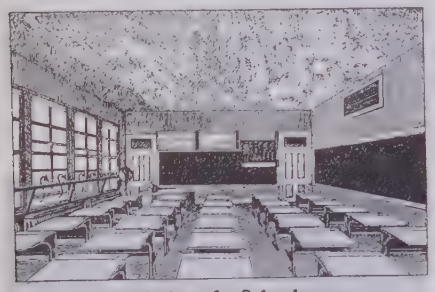
acid condition of the blood. This seems to activate a region of the brain (the respiratory center in the *medulla oblongata*) which causes nervous stimulation to the lungs and intercostal muscles and, finally, acceleration of the respiratory rate. The nervous control of respiration is also observed in the effects of a sudden dash of cold water on the skin, of emotions and of certain drugs.

The Products of Respiration. The essential changes resulting from respiration are the consumption of oxygen and the excretion of carbon dioxide. In addition, the air that is drawn into the lungs, whether it is dry or moderately damp, comes into intimate contact with the moist surfaces of the membranes of the nose, mouth, larynx, trachea, bronchi and lungs. The consequence is that the expired air becomes saturated with moisture and warmed to body heat. Water is also being continuously given off by the skin. The end result is that the body loses to the atmosphere around it about three pints of water a day and about as much heat as is given off by a candle burning continuously. In addition, the body is also excreting (via the lungs and skin) volatile, ill-smelling substances of uncertain composition.

Ventilation. The net effect upon the atmosphere of the presence of an individual is the consumption of oxygen and the excretion of carbon dioxide, water vapor, heat and ill-smelling products. It is evident that if one or more human beings remain in a more or less enclosed space, the air is subjected to chemical and physical changes and it frequently becomes necessary to provide for the maintenance of proper air conditions. Except under very extreme circumstances, the consumption of oxygen by humans in a room is inconsiderable, and actual oxygen deficiency rarely ever occurs. Extensive experiments

Zone of Comfort

The zone of most healthful and most comfortable combination of temperature and humidity (shown in white).



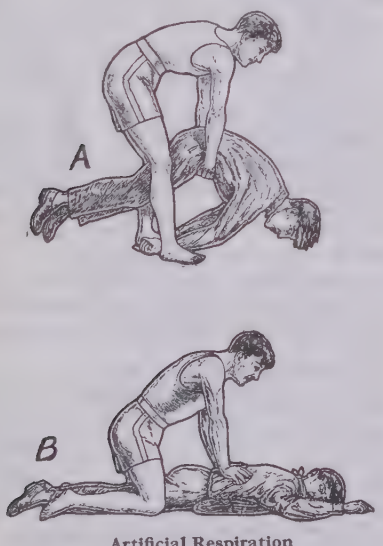
have demonstrated that the depressing effects of "bad air" are due to excessive heat and moisture rather than to increased carbon dioxide or reduced oxygen content. In addition, the smelly substances given off by human bodies and which may become perceptible in a close, crowded room or auditorium may have unfavorable effects upon the appetite.

The aim of ventilation is to provide proper air conditions. For most human beings the best temperature is between 64° and 68° Fahrenheit. The humidity of air is expressed in terms of "relative humidity" (the percentage of moisture contained in the air by comparison to the maximum which air can hold at the same temperature). The optimum relative humidity at favorable temperatures and with moderate air movement is about fifty per cent.

As the body loses heat it tends to warm the air about it. If there is little or no motion of the air, a "blanket" of warm air tends to form about the body and give a sensation of warmth. If the air is in motion, the warmth from the body is dissipated. Air in motion, therefore, tends to have greater cooling and evaporating power than quiet air.

The aim of ventilation is to provide clean air at proper temperature and humidity, in moderate motion and free from odors and noxious impurities. In a house or office where there are few people there may be sufficient ventilation through cracks around windows and doors. A window open a few inches will ordinarily suffice for air change if there is appreciable difference between the indoor and outdoor temperatures, or if there is a wind blowing. In very cold weather windows may be closed. In a schoolroom the same ends may be attained by window ventilation, with or without ducts by which

the warmed air in the room may escape as it rises. In cold climates or at wintry seasons of the year it is wise to arrange the heating system so that the cool air that enters is tempered as it comes in. Under many conditions, as in a large auditorium or theater, it may be necessary to use more elaborate systems



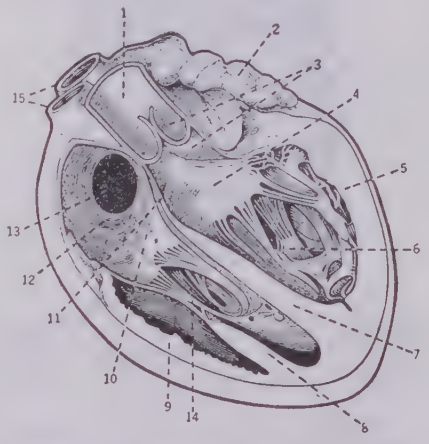
Ventilation of a Schoolroom

Fresh air enters through the window. Draft is broken by the glass plates. The air is warmed as it passes over the radiators and when warm and stale escapes through the openings of the ducts near the ceiling.

of fans and ducts to bring fresh air in and to remove vitiated air through many openings judiciously distributed to avoid drafts.

Artificial Respiration. Death ensues if respiration is stopped as by drowning, electrical shock, gas poisoning or choking. It is often possible to save the life of the individual by inducing and, for a time, maintaining artificial respiration. The important thing is to start the artificial motions as soon as possible, because seconds are valuable. Even

Artificial Respiration

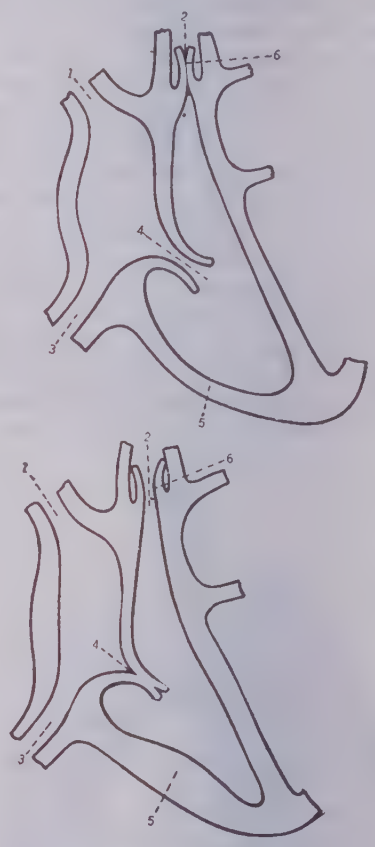


In (A) water is being dislodged. In (B) is shown the Schaefer method of artificial respiration. The method in (A) should always be used first and sometimes is all that is necessary.

In the Schaefer method, the victim is placed in the prone position and the tongue tied out. The operator takes the position illustrated and alternately throws his weight on and off the victim. This is repeated about fifteen times per minute (once every four seconds).

if the patient does not appear to respond, the artificial motion should be continued until a physician has been called and has definitely decided that the individual is dead. A simple method of inducing artificial respiration is illustrated in the drawing.

The Circulatory System. In a complex multicellular body it is necessary that there be some device by which food is constantly supplied to, and waste products as constantly removed from, each individual cell. The organs that constitute the circulatory system accomplish these ends by circulating the blood through the body. The blood reaches all the parts, bringing foods and removing wastes.



The structure of the circulatory system can be visualized as a central pump (the *heart*) with a series of pipes or tubes (*arteries*) running out to the several organs (including the lungs, liver, spleen, stomach, pancreas, intestines and kidneys), and a series of tubes (*veins*) running back again to the pump, the whole system being filled by a complex fluid (*blood*). There are really two circulatory systems away from and back to the heart: one through the lungs where the blood brings food, takes up oxygen from the air and gives off carbon dioxide and water and carries off wastes; the other through the brain, limbs and visceral organs where the blood brings food and removes wastes. In the alimentary tract the blood obtains most of the food for the body.

Section of Heart

A section of the human heart, showing—1. Aorta; 2. Left auricular appendage; 3. Aortic valve; 4. Bicuspid (mitral) valve; 5. Wall of left ventricle; 6. Papillary muscle; 7. Ventricular septum; 8. Anterior papillary muscle; 9. Wall of right ventricle; 10. Tricuspid valve; 11. Membranous septum; 12. Pectinate muscles; 13. Ostium of inferior vena cava; 14. Chordae tendinae; 15. Right pulmonary veins.

The Heart. This is essentially a hollow mass of muscle which is divided up by partitions into four compartments. The upper ones are called the *auricles* or *atria*, the lower ones the *ventricles*. The former are little more than storage places into which the blood empties upon returning to the heart. By the contraction of the auricles and expansion (relaxation) of the ventricles, the blood is driven into the latter. Then as the thick-walled and powerful ventricles contract, blood is pumped out into the main arteries. The sequence of changes in the heart is: (1) contraction of the auricles; (2) contraction of the ventricles; (3) relaxation of the heart; (4) rest. This sequence is repeated over and over again throughout the life of the individual. The two auricles and the two ventricles contract simultaneously. The period of contraction is called *systole*, the period of relaxation, *diastole*. During diastole, blood is flowing from the veins into the auricles and from the auricles through the open auricular-ventricular valves into the ventricles. When the auricles contract there is actually little pumping of blood. When the powerful ventricles contract, the valves between them and the auricles are shut and the blood is driven out into the arteries (the pulmonary artery from the right ventricle and the aorta from the left ventricle). The blood cannot flow back into the heart from

Diastole and Systole

The upper diagram shows diastole and the low systole. 1. Superior vena cava; 2. Pulmonary arter 3. Inferior vena cava; 4. Tricuspid valve; 5. Righ ventricular wall; 6. Pulmonary valve.

the pulmonary artery or aorta because of the one-way valves (semilunar valves).

The bulk of the heart is in the ventricles. Under unusual circumstances, such as leaky or defective valves, the heart wall enlarges (hypertrophies) in order to compensate by doing more powerful work. Normally the heart beats about seventy or seventy-five times each minute in adults, somewhat faster in children and slower in older persons. The beat of the heart can be felt as the *pulse* by placing a finger over the artery in the wrist or over the apex of the heart, and can be heard by listening to a person's chest. The heart ordinarily pumps about four quarts of blood each minute. During a day the work done by the heart in an average adult is equivalent to raising a mass of 200 tons through a distance of one foot. In a lifetime the work done by the heart is equal to th

energy that would be required to lift it to the moon.

Arteries and Veins. The blood vessels are called arteries and veins according as they carry blood from or to the heart. The main arteries, large, thick-walled tubes with muscular walls, branch into smaller and smaller tubes as they proceed, until the thin-walled capillaries are reached in the tissues. The blood proceeds from the capillaries to the very

Valves in the Veins

1. Section of vein with valve closed; 2. Same, valve open; 3. External view.

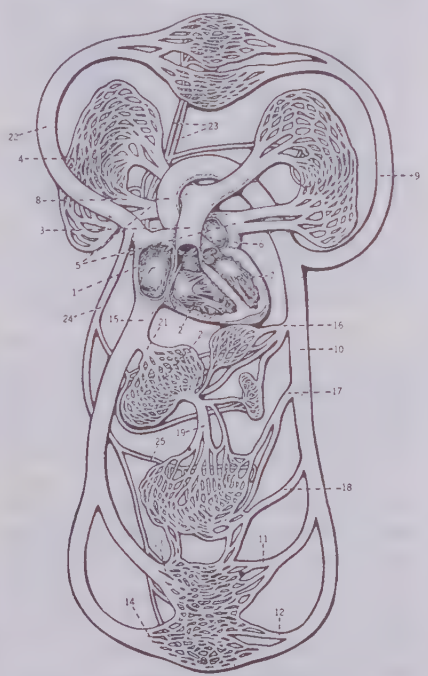
small veins, and thence to larger and larger veins and finally back to the heart. The veins are far less muscular than the arteries, but are equipped with one-way valves which permit the blood to flow only towards the heart. The sequence of vessels is: arteries, arterioles, capillaries, venules and veins.

Blood. The blood is a fluid (the *plasma*) in which are dissolved food substances, waste products and many other constituents, and in which are suspended two types of cells,

Red Corpuscles at Work

Showing interchange of food and waste materials between the red corpuscles and the tissue cells. At the bottom is shown the migration of white corpuscles from the blood stream.

the red (*erythrocytes*) and the white (*leukocytes*) and certain minute particles called *blood-platelets* which are concerned with the clotting of blood when it is shed or injured. The red cells are so called because they are rich in red coloring matter (hemoglobin) that contains iron. The hemoglobin has the remarkable property of entering into loose combination with oxygen and carrying it from regions where the oxygen supply is abundant (the lungs) to regions where the oxygen con-



Leukocyte at Work

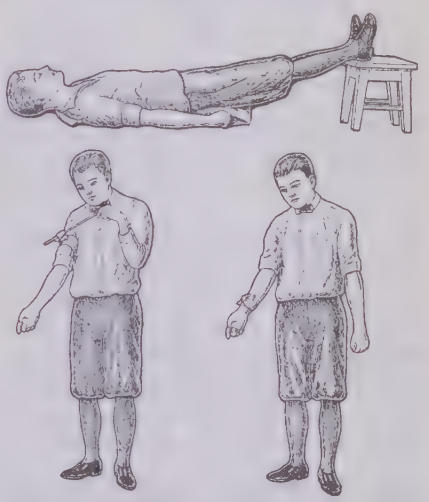
Leukocyte (phagocyte) taking up and digesting a pair of bacilli.

tent has been depleted (the other tissues). The white cells are not really white: they are colorless. They serve principally to engulf and destroy foreign particles like bacteria. When blood is shed it clots and later separates into two parts—solid *fibrin clot* and fluid *serum*.

The blood is contained in vessels and does not actually come in contact with the tissue cells. The fluid which oozes out of the blood vessels and which is much like the blood plasma actually bathes the cells. This fluid is called *lymph*. The transfer of food substances and oxygen from the blood to the

Scheme of Circulation

1. Right atrium; 2. Right ventricle; 3. Pulmonary artery; 4. Pulmonary circulation; 5. Pulmonary veins; 6. Left atrium; 7. Left ventricle; 8. Arch of aorta; 9. Superior vena cava; 23. Right lymphatic duct; 24. Thoracic duct; 25. Lacteals.



cells and of waste products and carbon dioxide from the cells to the blood is actually accomplished by diffusion through the lymph. The lymph is being continually formed from the blood. It is also collecting into vessels called *lymph channels* or *lymphatics*, and eventually it returns to the blood through the main lymph vessel called the *thoracic duct*.

Circulation in the Body. The main paths of the actual circulation of blood can be followed in the diagram.

Much of the energy used in circulating the blood comes from the action of muscles which, as they contract, press upon veins and push the blood along (in the proper direction because of the one-way valves in the veins), and by suction produced in the thoracic cavity by the respiratory movements of the chest and diaphragm.

Fainting. This is commonly the result of defective circulation in the brain (*cerebral anemia*), and not to disease of the heart. The proper treatment for fainting is to lay the person on his back with the feet higher than the head.

First Aid for Bleeding. In case of injury to an artery, recognized by the intermittent spurting of the bright red blood, a bandage of clean linen should be placed around and above the injured part and turned tight with

First Aid

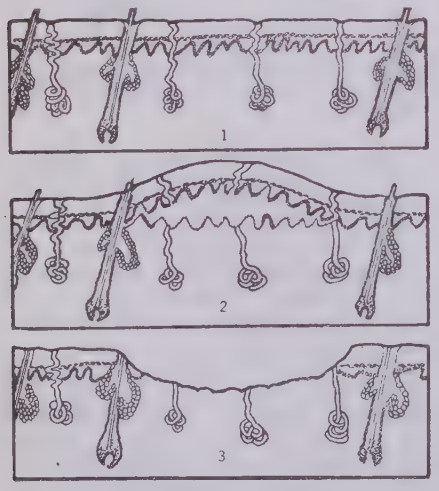
At the top is illustrated first aid for fainting; at the left, for arterial bleeding; at the right, for venous bleeding.

a stick or other suitable object. It should be released as soon as bleeding stops or a physician arrives. Bleeding from a vein, recognized by the fact that it is slower and more regular and that the blood is of darker color, can usually be controlled by mild compression with a bandage. Pressure at the points indicated in the picture will usually control bleeding from the related blood vessels.

Heart Disease. Diseases of the heart and blood vessels cause more deaths than any other single cause, though they usually come late in adult life. Proper hygienic living is the main rule in avoiding premature disease of these parts. It is also important to avoid poisoning from alcohol, infected teeth, tonsils, adenoids and from infectious diseases in general. Work, rest, sleep and diet in moderation and balance are the best known rules for the care of the heart and blood vessels.

The Glands of Defense, Secretion, Excretion and Regulation. Under the designation of "glands" are included many organs in the body which serve a variety of functions. For some, one or more of their functions have long been known; for others, precise infor-

mation is still largely lacking. In the study of this field physiology still has some of its most significant opportunities for discovery. Indeed, there is probably not a single glandular activity in the body whose mechanism is clearly understood at the present time (1931). For such a large and prominent gland as the



The Protective Skin

The skin is a protection against infection. A pin is shown penetrating through the skin. The cells of the skin, the pin and the bacteria on the point are drawn in correct proportions. A fairly deep prick is necessary to introduce bacteria into the tissues beneath the skin.

spleen it is even uncertain whether it has any specific functions, and if it has whether they are primarily concerned with circulatory, digestive or other systems. It appears at this time that the spleen serves as a reservoir for blood in the internal parts of the body.

Glands as Defense Organs. I. Lymph Glands. Chief among those which provide defenses of the body against injurious agencies are the *lymph glands.* They are distributed every-

Normal and Injured Skin

This diagram shows the reaction of the skin to external injury; 1. Normal; 2. Blister; 3. Charred or severe burn.

where in the body. Some are quite large; others are of microscopical dimensions. They serve principally to filter out of the blood and lymph foreign bodies like bacteria, dead cells and dust particles, and to hold them for digestion by white blood cells or other phagocytes (see p. 987).

II. The Liver. This organ has been described in the discussion of digestion because it manufactures the bile which is secreted into the duodenum to aid in the digestion of fats. It is also a gland of defense because the blood which collects the products of digestion from the alimentary tract first passes the liver in the portal circulation and is there purified. There is reason to believe that many products of digestion are poisonous (toxic) and that they are de-toxified or rendered harmless in the liver. Bacteria and other foreign bodies are also filtered out of the blood and destroyed in the liver.

The skin and many other tissues also provide defense mechanisms; but they are described elsewhere, because their principal glandular functions are of a different kind.

Glands of Secretion. Among the glands of secretion, those which are primarily concerned with the manufacture of secretions that aid in the digestion of foods have already been described (salivary, gastric and intestinal glands, liver, pancreas). In addition, mention may be made of the *mammary glands,* the glands in the breast, which are present in both the male and female but which function to secrete milk only in the recently pregnant female.

Glands of Excretion. The principal excretory glands are the lungs, kidneys and those of the skin. Of these, the first has already been described in relation to its respiratory functions, because the excretion of carbon dioxide is intimately related to the absorption and consumption of oxygen.

The Kidneys. The *kidneys* are the chief organs of excretion in the body. They are paired organs, lying in the back of the abdominal cavity at either side of the spinal column. As the blood circulates through them, waste products which have been collected from the tissues throughout the body are removed. This is accomplished by a flow of water and of urea and many other substances dissolved in the water from the blood through the walls of the tubules and capsules of the kidneys. This watery material (urine) that is collected from the blood in the cortex of the kidneys accumulates in the cavities in the pelvis of each of these organs, passes down the ureters to the urinary bladder and is stored there until expelled from the body. The ordinary, healthy person should drink each day about six glasses of water in addition to the water that occurs in solid foods in order to provide sufficient fluid for the proper excretion of body wastes.

The Skin. This organ or group of organs serves three important functions: protection of delicate tissues, excretion of waste products and regulation of body temperature. Each of these is important. As a protective organ, the skin is remarkably efficient though it is, in general, only from one one-hundredth to one-tenth of an inch thick. It guards the sensitive tissues against mechanical injury, evaporation, heat, cold, excessive sunlight,

Skin and Hair

In this detailed study we have, in A, the hairy skin; in B, normal skin with contracted blood vessels, retaining heat and moisture; in C, skin with excessive circulation, flushed and losing considerable quantities of heat. 1. Epidermis; 2. Dermis or corium; 3. Subcutaneous tissue; 4. Scaly layer; 5. Clear layer, stratum lucidum; 6. Granular layer; 7. Prickle cell layer; 8. Cylindrical cell layer; 9. Tactile corpuscle (Meissner); 10. Ruffinian corpuscle; 11. Paccinian corpuscle; 12. Arrector pili; 13. Hair falling out; 14. Sweat gland (cross-section); 15. Sebaceous gland; 16. Hair follicle; 17. Cortex of hair; 18. Papilla of hair; 19. Dermic coat of hair; 20. Vein; 21. Artery; 22. Nerve; 23. Sweat gland; 24. Body pore of sweat gland; 25. Duct of sweat gland; 26. Adipose tissue; 27. Vein.

effects of water or other fluids. It is unusually thickened over certain parts of the body where it is exposed to frequent pressure or friction (callouses, corns). Ordinary bacteria cannot penetrate through the unbroken skin. The sebaceous glands in the skin secrete an oily substance to keep the hair in good condition so that it may serve protective functions. The same protective function may be mentioned for the nerve endings in the skin that give the sense of touch and also heat and cold.

The excretory function of the skin is primarily associated with the numerous sweat glands which it contains. They draw waste products and water from the blood vessels to make the sweat. This is passed on through their ducts to the pores. The sweat is then discharged upon the surface of the skin.

The third function of the skin is concerned with the maintenance of the body temperature within a narrow range of fluctuation (average 98.6° Fahrenheit or 37° Centigrade).

"When it is desirable that the body should conserve heat, the blood vessels of the skin contract; but when an excess of heat is pro-

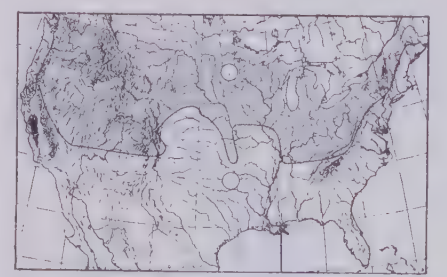
duced in the body by muscular exercise or when the outside temperature is high, these blood vessels dilate as shown, allowing an abundant supply of blood to come to the surface and cool off. At the same time the nerve supply of the sweat glands is stimulated, causing them to secrete actively. The evaporation of the secretion of sweat cools the body mechanically. Normally, about two quarts of perspiration are passed off daily. This amount may be greatly exceeded in hot weather or in violent exercise.

"Excessive clothing and overheated atmospheres interfere with the normal function of the skin in controlling temperature, and weaken the reactions outlined above. Tight clothing also interferes with circulation of the skin, as well as with the function of other structures.

"Frequent washing and bathing is necessary to remove not only dirt that accumulates but also the products of the sebaceous and perspiratory glands. Cold bathing is very valuable as a stimulus to the heat regulating machinery of the skin." (Winslow.)

Ductless (Endocrine) Glands. These are glands which have no true ducts and discharge their products (*hormones*) directly into the lymph or blood stream. The functions of many of these are not yet clearly understood and only the principal ones will be mentioned here because they seem to serve as regulators of the body.

Pituitary Gland (*Hypophysis*). This is a small gland at the base of the brain whose



What Happened to the Tadpoles

An experiment illustrating the effect of the thyroid gland upon growth and development of the frog. Upper row—Normal growth and development. Middle row—Thyroid gland has been removed. Growth without development. Lower row—Thyroid fed in excess. Premature development and insufficient growth.

hormone influences growth. Disease of this gland may lead to the production of too much or too little of this substance and may be associated with excessive size (giantism) or diminutive size (dwarfism) of the body. Disorders of the gland may also lead to other types of abnormalities. The *pituitary* is known to control the activity of the sex glands.

Thyroid Gland. The *thyroid* consists of two lobes connected by a narrow band of tissue (the isthmus) lying in front of the trachea. Its hormone is important in the regulation of the rate at which the tissues of the body live, the activity of the nervous system and the growth of the body. Perhaps it has other functions not yet clearly understood. Its effect on growth is indicated in the illustrations. The normal development of a tadpole and frog is shown in the first row in illustrations. In the second row the tadpole whose thyroid has been removed continues to grow without metamorphosis into the adult form, the frog. In the third row is shown a tadpole of the same age as the former two, but which has been fed an excess of thyroid extract. It has developed prematurely into a frog which is normal except that it does not attain normal size. In human beings who live in parts of the world where iodine is scarce in water and foods,

Iodine Map

①The part of the United States in which the iodine content is inadequate in the food and water is termed the goitre region (over five cases of goitre per thousand persons in the U. S. Army draft). ②Where the iodine supply is adequate and goitre is relatively rare.

a disease of the thyroid is relatively common because the hormone of this gland contains iodine. If iodine is lacking, the gland undergoes enlargement (hypertrophy) as though to compensate by mass action for the lack of material for the manufacture of the hormone. When the gland becomes enlarged there is a swelling in the front of the neck. This condition is called *goitre*. The thyroid may become enlarged from other causes so that it is important to consult a physician as soon as even a slight enlargement or swelling is noticed. Goitre is far more common in girls than in boys and in women than in men. If the physician finds that enlarged thyroid is of the kind due to a shortage of iodine and too little thyroid secretion (hypothyroidism) and he discovers it in the early stages he can prescribe iodine in the diet and quickly effect a cure. Delay makes his problem far more difficult. Iodine should not be taken except upon a physician's recommendation.

Suprarenal (*Adrenal*) *Glands.* These are small, glandular bodies which lie on top of the kidneys, which are the renal glands. The suprarenal hormone resembles the thyroid hormone in many respects, but has additional properties.

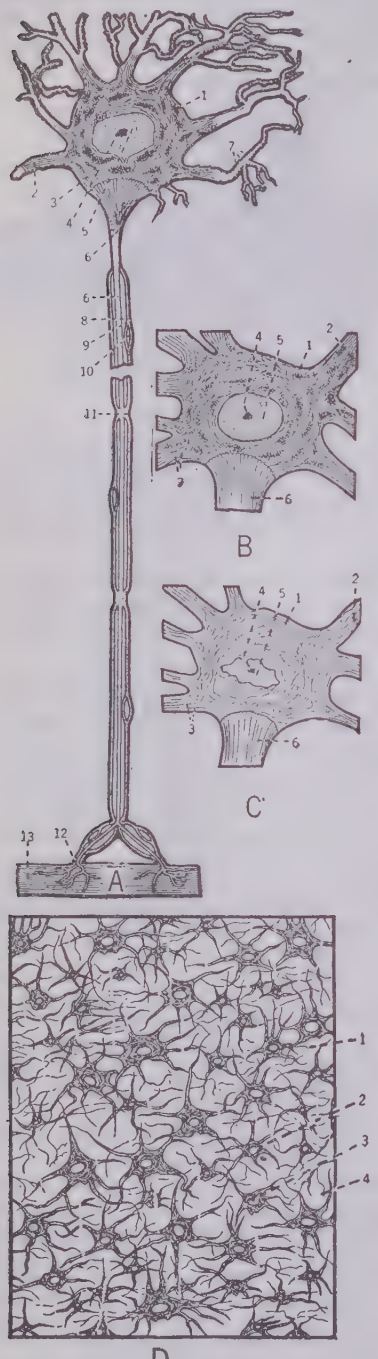
"It also has a special function in emergencies. Its hormones affect the nervous system and the circulatory system, so that the blood vessels in the skeletal muscles, in the brain and in the lungs dilate. This makes available an unusually large supply of oxygen and of nourishment for the parts of the body that are called on in emergencies. At the same time, glycogen is given out by the liver in larger quantities, and there is contraction of the spleen and of blood vessels for the alimentary tracts and other structures that are not so essential to functions under these conditions." (Winslow.)

Why He Ran

The stout and elderly man, under the influence of fear, is outrunning the athlete on the other side of the fence. This imaginative picture illustrates the principle that certain body functions are affected by emotions. Fear is supposed to stimulate the adrenal glands and the strength and activity of many parts of the body are modified by the increased gland secretion (hormone).

In times of fear, anger or other emotional stress, the body is capable of unusual physical efforts because of increased secretion from the suprarenal and other glands.

Pancreas. The bulk of this gland consists of lobules whose cells manufacture the pancreatic juice which is secreted into the duodenum and which is active in the digestion of food. In addition, scattered throughout the gland, there are groups of cells called the "islands of Langerhans" which secrete a hormone into the blood. Disease or injury of the pancreas which involves extensive or complete interference with the functioning of these cells leads to an imperfect utilization of sugar in the body and to a disease called *diabetes mellitus*.



Reproductive Glands. There are some reasons to believe that the testes in the male and the ovaries in the female produce hormones. A number of other glands of the reproductive system are alleged to have endocrine functions. The facts are not well established at this time (1931).

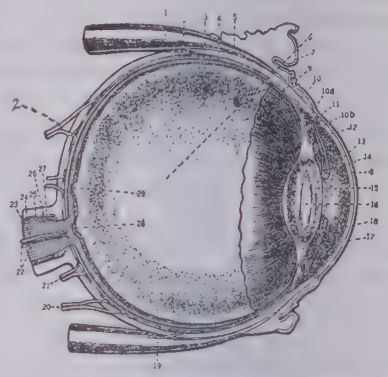
The Nervous System. It has already been explained that in part the activities and coördination of parts of the body are controlled by the hormones of the endocrine glands. The principal control, direction and harmony of action in the body is, however, due to the integrating (coördinating) action of the nervous system. The chief parts are the *brain*, *spinal cord*, the *ganglia* (groups of nerve cells) and the *nerves*.

The Brain. The principal parts of the brain are the *cerebrum*, the *cerebellum*, the *pons* and the *medulla oblongata*. Twelve pairs of nerves (the cranial nerves) are offshoots from the brain. These nerves are associated with special senses such as seeing, smelling and hearing.

The Spinal Cord. Continuous with the medulla is the long spinal cord which runs down from the head along the length of the back and which is enclosed within the spinal

column. From the cord thirty-one pairs of nerves (the spinal nerves) are given off. There are also two rows of ganglia (the spinal ganglia) in front of and on either side of the cord and connected with it by nerve fibers.

Nerve Cells



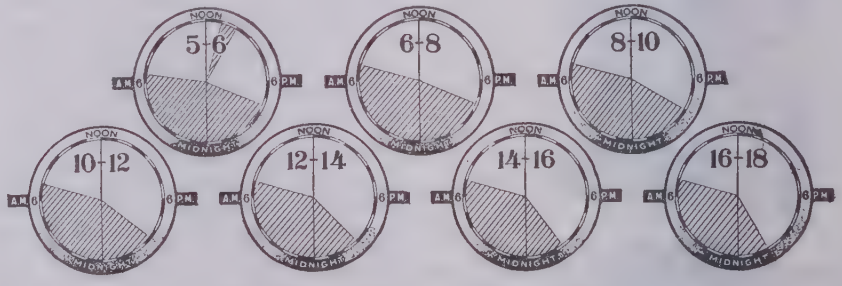
A. Nerve cell connected by axon to a muscle fiber. B. Normal nerve cell with large nucleus and many chromatophile bodies. C. A nerve cell exhausted by fatigue, or stimulants like alcohol. Note shrunken state of nucleus and absence of chromatophile bodies. D. Diagram illustrating how nerve cells are interrelated in he brain. In A, B and C, 1. Chromatophile bodies (Nissl's granules); 2. Dendron or dendrite; 3. Neurofibrils; 4. Nucleolus; 5. Nucleus; 6. Axon; 7. Gemmules; 8. Medullary sheath; 9. Neurolemma; 10. Nucleus of neurolemma; 11. Node of Ranvier; 12. End arborization of teledendrion; 13. Striate muscle fiber. In D, 1. Axon; 2. Dendrite; 3. Nucleus; 4. Hyaloplasm.

The Nerves. The neuron, or nerve cell, has already been described (see p. 978). From a functional point of view, the nerves may be divided into two classes according to whether they carry sensations to the central system (brain and cord) where the nerve cell is located, or carry impulses from the central system or nerve cell to the muscle, organ, blood vessel, and so forth, with which the nerve is related and whose activity it affects or controls. The former are called *afferent* and the latter *efferent* nerves.

The Reflex Arc. The simplest kind of nervous control of organs or tissues is exhibited in what is called the *reflex*. A stimulus is given the nerve ending as by a prick of the skin, a burn or shock. This passes along an afferent nerve to a ganglion in the cord. There this "sensory" stimulus becomes transformed into a "motor" stimulus which passes along an efferent nerve and causes muscles to contract and draw away the part of the body that was being stimulated. This cycle is called the *reflex arc* because it may happen without any consciousness or voluntary interference. Indeed, many such reflexes, even if a message is relayed from the spinal ganglion up the spinal cord to the brain, may be completed before the brain has been made aware of the primary stimulation. In behavior of this kind the nervous system is often likened to a telephone system, with its extensive wires and cross connections, switchboards, automatic controls, and so forth. The brain is then analogous to the "central" which controls the switchboard. In complexity, however, the nervous system so far exceeds any known mechanical system that man has only scratched the surface of the problem of understanding the workings of the nervous system.

Nervous Fatigue and Rest. Like any other living tissue, the neurons carry on active metabolism (chemical changes of life processes) in which repair must keep pace with use and injury. Rest is just as essential to nerve as to muscle tissue. The chief occasion for rest of the parts of the nervous system is when the individual is asleep. It is also important that the organs of this system be protected from drugs or poisons that speed it up or injure its parts. Chief among the common substances that are injurious to the nervous system is alcohol. Even small doses of this substance reduce the efficiency with which the system operates, and larger doses may be actually poisonous. Other substances like coffee, tea or tobacco smoke are harmful to the nervous system when used in excessive quantities.

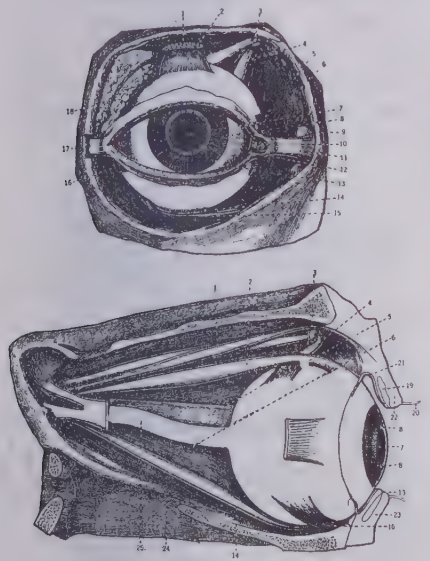
The Special Senses. All normal persons are equipped with organs for the so-called "special senses"—*seeing, hearing, smelling, tasting* and *touching*. These senses are made possible by highly specialized types of organs (as eye, ear, nose) at the ends of special sensory nerves. These organs provide us with the means of relating ourselves to the environment. With their aid we recognize what is going on about us.



Side View of Eye

1. Lateral rectus muscle; 2. Vortex vein; 3. Sclerotic coat; 4. Choroid coat; 5. Retina; 6. Vitreous humor; 7. Conjuctiva palpebrarum; 8. Epithelium of cornea; 9. Ora serrata; 10. Ciliary body; 10a. Ciliary muscle; 10b. Circular fibers of ciliary muscle; 11. Canal of Schlemm; 12. Iris (with radial fibers); 13. Iris (sphincter muscle of pupil); 14. Cornea; 15. Aqueous humor; 16. Crystalline lens; 17. Zonule of Zinn, ciliary zonule; 18. Posterior chamber of eye; 19. Medial rectus muscle; 20. Long posterior ciliary artery; 21. Short posterior ciliary artery; 22. Central blood vessels of optic nerve; 23. Optic nerve; 24. Dura mater; 25. Subdural space; 26. Arachnoid coat; 27. Subarachnoid space; 28. Blind spot; 29. Yellow spot.

The Eyes. Perhaps most important among the organs of special sense are the eyes. These are very delicate and very complex structures which lie in protecting cavities of bone. The eye is often likened to a camera with a lens in front to focus an image upon a sensitive screen behind. To understand the proper care of the eye it is essential to know something about how it is constructed and how it functions.

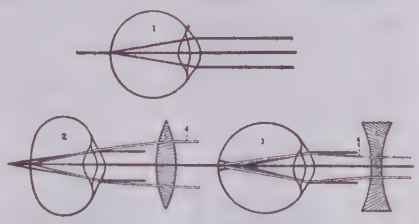


The eye is a ball-like structure with three coats, the outer one being the sclerotic, the middle one the choroid and the inner one the retina. The ball is divided into two chambers. The anterior, filled with the aqueous humor, has the jelly-like crystalline

Required Hours of Sleep for Different Ages

The large numbers indicate the ages. The shaded areas show the required hours of sleep to give the body adequate rest.

lens at its back; the posterior, filled with vitreous humor, is lined by the retina which is made up of blood vessels and the extremely complex, specialized endings of the optic nerve which runs to the brain. The sclerotic coat, seen as the white of the eye, has a round area in front (the cornea) which is transparent to light. The choroid coat below it has a round opening in front (the pupil) and around it a region which is pigmented (the iris) and from which the eye gets its color (black, brown, blue, gray or hazel). The iris is under the control of muscles which can expand or contract it so that more or less light enters the eye. The iris can be seen to change rapidly when emerging into a bright place from a dark room or by flashing a light upon the eye that has been covered for a few moments. As an excess of light strikes the eye, the iris contracts. The crystalline lens is attached to the choroid coat by special ligaments, termed *zonula of Zinn*. The ciliary muscle which is circular around the eye controls the tension of the ligaments. When the tension on the lens is increased, it is flattened;



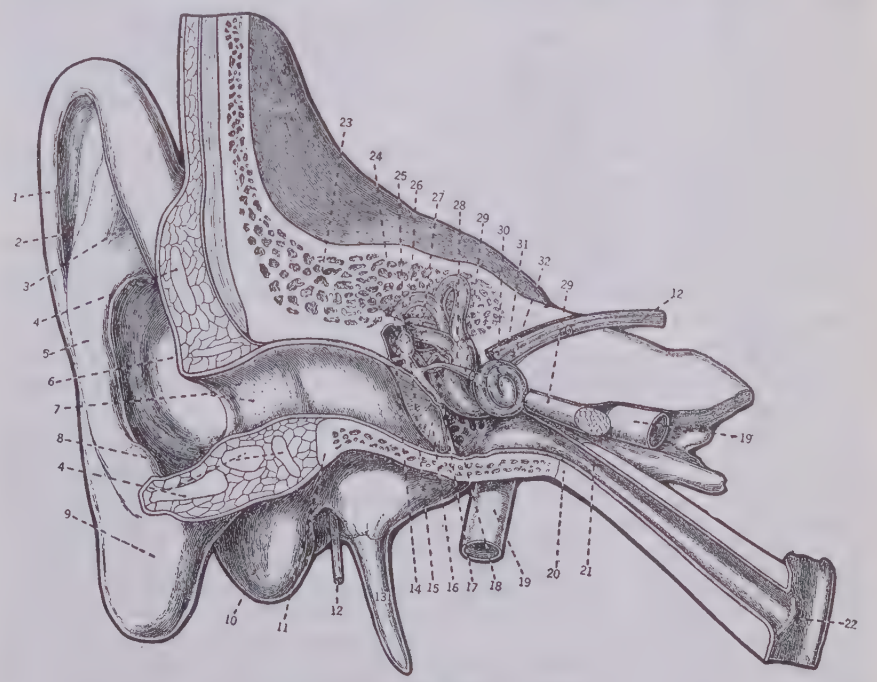
A Study of the Eye

Showing front (above) and side (below) views of the eye in its orbit. Note especially the muscles and ligaments. 1. Levator palpebrae superioris; 2. Superior rectus muscle; 3. Trochlea; 4. Superior oblique muscle; 5. Rectus medius; 6. Orbital wall; 7. Pupil; 8. Iris; 9. Lacrimal sac; 10. Caruncula lacrimalis; 11. Medial palpebral ligament; 12. Puncta lacrimalia; 13. Meibomian ducts, tarsal ducts; 14. Inferior rectus muscle; 15. Inferior oblique muscle; 16. Lateral rectus muscle; 17. Lateral palpebral ligament; 18. Lacrimal gland; 19. Tarsal gland, Meibomian gland; 20. Eyelash; 21. Conjunctiva; 22. Upper eyelid; 23. Lower eyelid; 24. Infraorbital fissure; 25. Optic nerve.

and when the tension is decreased, the lens becomes thicker and its surfaces more highly curved. By these means light from more or less distant sources is brought to a focus on the retina. With advancing age the lens tends to become hard and less easily variable in shape, and the choroid and the muscles become less responsive to stimuli and less accurate in functioning.

The retina is an extremely complex structure in which light produces chemical and physical changes of varieties which send suitable stimuli along the fibers of the optic nerve to the brain. There the stimuli are interpreted to give the impressions of light, color and so forth. The two eyes act together so that vision is single and stereoscopic, giving effects of distance and depth.

The eye is bathed continually by the secretion of the lachrymal gland. This



Normal and Abnormal Vision

1. Normal eye, with rays of light converging at focal point on retina; 2. Hypermetropic eye, with rays converging behind retina; 3. Myopic eye, with rays converging in front of retina; 4. Rays of light corrected by proper lens; 5. Biconvex glass; 6. Biconcave glass.

fluid normally flows over the eye and is drained off through the lachrymal duct at the nasal corner of the eye. When, under the influence of nervous or emotional stress or some local irritant this gland is unusually active, the excessive quantity of fluid which it secretes may overflow the eyelids as tears. The eye is also protected against injury or foreign bodies by the eyelids and eyelashes. The lids are controlled by muscles which are under voluntary control but which also operate under involuntary control.

Defects of Vision. The eyes are very frequently handicapped by abnormalities of structure and function. In the drawing, in (1) it is seen how a beam of light is brought to a focus on the retina in a normal eye. In (2), the eyeball is too short from front to back and the focus is "behind" the retina. To correct this, the lens of the eye must be made thicker (more convex) and the ciliary muscles that effect this change are called into use so often that serious strain results. The situation (*hyperopia* or long-sightedness) is corrected by means of a suitable convex lens or eye glass. In (3), the eyeball is too long (from front to back), the focus is in front of the retina and the correction of this condition (*myopia* or near-sightedness) is made with a suitable biconcave lens. When the surface of the cornea becomes irregular the image is indistinct on the retina (*astigmatism*). This can be corrected by suitably prepared eyeglasses. Everyone should have his eyes tested at least every year or two in order to detect the need for corrections when defective conditions are in their early states. Parents can often discover that a child's eyes need attention by the fact that he holds a book too close or too far away when reading. Some common eye defects can be corrected if given prompt attention. If the child's eyes tend to be "crossed" they should be examined by an eye specialist without delay.

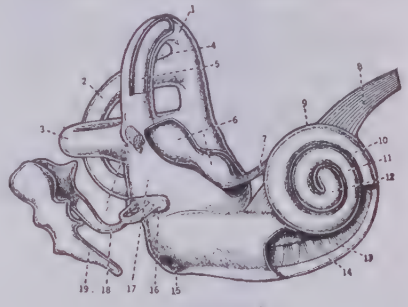
Color Blindness. This condition is more common than is sometimes supposed, many persons being unaware for years that their eyes are defective in discriminating colors. And yet complete color blindness is rare. Failure to distinguish red and green is not uncommon. Color blindness occurs far more often in men than in women.

The Ear and Associated Structures

1. Helix; 2. Scapha; 3. Fossa triangularis; 4. Cartilaginous portion; 5. Antihelix; 6. Concha; 7. Ceruminous glands; 8. Antitragus; 9. Lobule; 10. Mastoid process; 11. External auditory meatus, bony part; 12. Facial nerve; 13. Styloid process; 14. Anvil; 15. Hammer; 16. Tympanic membrane; 17. Stirrup; 18. Tympanic cells; 19. Carotid artery; 20. Eustachian tube, cartilaginous part; 21. Eustachian tube, membranous part; 22. Orifice of Eustachian tube in nasal pharynx; 23. Mastoid cells; 24. Lateral ligament of hammer; 25. Superior ligament of hammer; 26. Semicircular canal; 27. Tympanic antrum; 28. Vestibulum; 29. Tensor tympani muscle; 30. Cochlea; 31. Auditory nerve, vestibular branch; 32. Auditory nerve, cochlear branch.

Eye Strain. The commonest cause of eye strain is reading or otherwise using the eyes under conditions of too strong or too weak illumination. Particularly when reading the light should be shaded so that the eyes are not exposed to glare, and the light in moderate intensity should fall upon the object, not upon the eyes. For reading purposes a flickering light should be especially avoided. The correct distance for reading is from twelve to fourteen inches for the normal adult eye and somewhat less for children. When the eyes are being used continuously, for whatever purpose, they should be rested frequently by closing the eyelids or by looking off at the sky or some distant object. When the eyes have been irritated by dust, wind, excessive sunshine or glare they can be quickly soothed by being bathed with a saturated solution of boric acid.

Foreign Bodies in the Eye. When a foreign body such as dust particle gets into the eye, the eye should never be rubbed. If the body is not removed by gently drawing one lid over the other, it should be removed as soon as possible by a physician or other competent person who knows how to turn the lids back and remove the irritating object with the corner of a clean handkerchief or other suitable object.



The Ear. The ear is probably next to the eye in complexity and importance as an organ of special sense. It consists of three parts—the outer, middle and inner.

The Outer (External) Ear. This consists of the horn or trumpet-like part of flesh and cartilage that is ordinarily called "the ear." Its function is to catch sound waves and reflect them through the opening (external auditory meatus) into the auditory canal. The auditory canal is guarded by cartilage and at its beginning is lined with glands (ceruminous) which secrete a sticky material called "ear wax" that catches dust and dirt particles. Beyond this region is a bony canal which is terminated by a thin membrane (eardrum, tympanic membrane) stretched across it.

The Middle Ear. Just beyond the eardrum is another cavity (tympanic cavity) which connects with the upper part of the throat (naso-pharynx) by the Eustachian tube or canal. In the tympanic cavity lie three bones called the "hammer" (malleus), "anvil" (incus) and "stirrup" (stapes), according to their shapes and functions. The hammer is fastened to the eardrum so that it is made to vibrate when sound waves entering the ear make the drum vibrate. The vibrating hammer strikes upon the anvil and the vibrations of the anvil are in turn transmitted to the stirrup which in turn transmits them to the inner ear. The net effect of this ingenious arrangement of three bones is that the vibrations of the eardrum are transmitted to the inner ear after they have been magnified about thirty times. The Eustachian canal, being normally open to the throat and mouth, permits equalization of the pressure on the inside of the eardrum with that on the outside. When blowing the nose, especially when one is suffering with a cold, it is extremely important to keep the mouth open. Otherwise, in the act of blowing, mucus (and bacteria) may be driven into the Eustachian canal and into the sinuses (cavities in the bony structures in the nose) and lead to painful and serious disease.

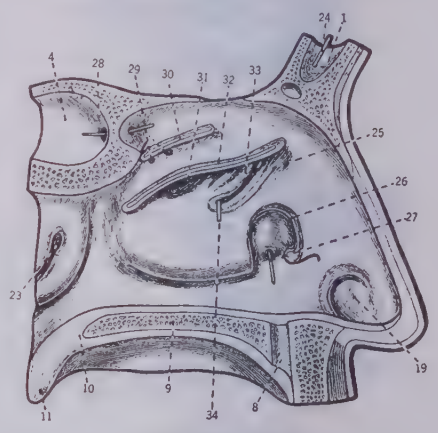
The Inner (Internal) Ear. This consists of two functional and structural parts, one concerned with hearing and the other with balancing and sense of position and direction.

Hearing is accomplished by the transmission of vibrations from the stirrup bone to the fluid in a part of the middle ear which is called the "cochlea" because it is spiral-shaped like a conch or snail shell. The motion of the fluid in the cochlea causes vibration of

The Labyrinth

This includes the cochlea (9), which is the organ of hearing; the semicircular canals (1, 2, 3), which are the balancing organs, and the bones of the middle ear (16, 18, 19), which transmit the vibrations of the ear drum. 1. Superior semicircular canal; 2. Posterior semicircular canal; 3. Lateral semicircular canal; 4. Bony labyrinth; 5. Membranous labyrinth; 6. Ampullae; 7. Branches of vestibular nerve to ampullae of semicircular canals; 8. Acoustic or auditory nerve; 9. Cochlea; 10. Basilar coil of cochlea; 11. Middle coil of cochlea; 12. Apical coil of cochlea; 13. Nerve of cochlea within spiral lamina; 14. Basilar membrane; 15. Fenestra rotunda or cochlear fenestra; 16. Stirrup (stapes), fitting into fenestra ovalis or vestibular fenestra; 17. Vestibule; 18. Anvil (incus); 19. Hammer (malleus).

hairlike endings of the auditory nerves. Stimuli pass along the nerve to the temporal region of the brain and set up sensations there which are interpreted as sound.



The other function of the inner ear is accomplished by the semicircular canals. There are three of these structures at right angles to each other. They contain a fluid (endolymph) and nerve endings. Any motion or change in position of the head results in motion of the fluid and this in turn results in stimulation of the nerve endings. The stimuli which pass along a branch of the auditory nerve to the brain set up sensations there. Early in life the individual learns how to interpret these sensations so that they enable him to balance the body or walk in a straight line even when blindfolded.

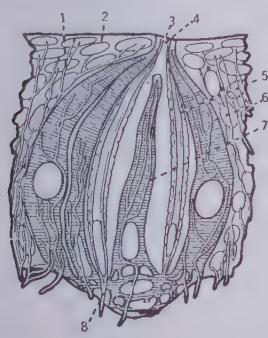
Care of the Ears. In cleaning the ears and removing wax use a damp cloth. Under no circumstances should the ears be cleaned, probed or poked with any hard or pointed object. Serious injury may be done to the ear drum in this way. When blowing the nose—normally, and especially when one has a cold—be sure to keep the mouth open. Otherwise there is danger of blowing mucus and bacteria into the Eustachian canal from the nasal cavity and starting infection of the middle ear. When water has entered the external ear, as when swimming, it should be removed by inclining the head.

If earache occurs, consult a physician at once. Do not delay even a single day because serious complications may develop rapidly.

The Nose. This organ serves a number of purposes, such as respiration, in addition to being the site of the special sense of smell. The nasal cavity lies behind the nose and nostrils and above the roof of the mouth. Opening from it by minute pores are a number of pocket-like cavities (sinuses) in the adjacent bony structures, the mouth of the Eustachian canal and the end of the lachrymal (tear) duct. The olfactory nerves have endings on the bones in the nose which are called "the turbinates." These nerve endings are stimulated by particles in the air brought to them by inhalation, and the stimulations, transmitted to the brain by the olfactory nerve, set up in the brain reactions that are interpreted by the individual as sensations of smell. In time of "cold" or other disease of the nose, inflammation may render the olfactory nerve endings incapable of detecting many odors. Many agencies other than bacteria can irritate the nose and cause an increased secretion of mucus by the nasal mucus glands. This condition, which is called "catarrh," can be brought about by dust, fumes, dry hot air, pollens of plants (hay fever) or some similar cause.

Matter suspended in the air that is breathed tends to adhere to the moist mucous membranes. This material may be of no consequence—except as it requires removal—or may be injurious if it contains irritating particles or disease-producing microbes. Dust, fumes, and the spray from coughing or sneezing persons should be avoided.

The Nasal Cavity



Showing the openings to the sinuses, to the ear and to the exterior. 1. Frontal sinus; 4. Sphenoidal sinus; 8. Incisive foramen; 9. Hard palate; 10. Soft palate; 11. Uvula; 19. Vestibule of nose; 23. Ostium of Eustachian tube; 24. Bristle in opening of frontal sinus; 25. Semilunar hiatus; 26. Cut edge of inferior turbinate; 27. Bristle in opening of nasolacrimal duct; 28. Bristle in opening of sphenoidal sinus; 29. Opening of posterior ethmoidal cells; 30. Cut edge of superior turbinate; 31. Opening of middle ethmoidal cells; 32. Cut edge of middle turbinate; 33. Bulla ethmoidalis; 34. Bristle in opening of maxillary sinus.

The Tongue. Most of the so-called "tastes" which we detect in eating and drinking are really smells of aromatic or volatile particles which reach the nose from the mouth. Sweetness, sourness, saltiness and a few others are true "tastes" which are detected by certain special sense organs (taste buds) located in the tongue. The buds that are especially capable of detecting sweetness are located at the top of the tongue. Those that detect sourness are along the sides of the tongue, and those concerned with bitterness are on the back of the tongue. The taste

buds have nerve endings that receive special taste stimuli and transmit them to the brain.

Organs of Touch. The sense of touch is associated with special types of nerve endings which are widely distributed in the skin. They occur particularly in the form of the tactile corpuscles (corpuscles of Meissner, end bulbs of Krause, Ruffinian and Paccinian corpuscles) and are particularly numerous in the skin of the finger tips and palms of the hands.

Mental Hygiene. The nervous system is the seat of the mind and the energy of mental processes is derived from the energy of the body. Variations in the operation of the organs and the distribution of the blood supply are quickly reflected in mental moods and humors. This is easily noted in inability to do mental work, in irritability and other characteristics when the body is tired; or in laziness, sleepiness directly after a meal; or in mental vigor and normal cheerfulness when the body is refreshed by rest or sleep. The mind becomes extremely inactive or even ceases to exist (unconsciousness) when physical or chemical disturbances in the body

Taste Bud

1. Nerve fiber; 2. Epithelium of mouth; 3. Hairlet (gustatory hair); 4. Gustatory pore; 5. Gustatory (neuroepithelial) cell; 6. Sustentacular cell; 7. Rod cell; 8. Gustatory nerve fibril.

exceed certain specific limits. It is therefore not surprising that mental hygiene and physical hygiene are intimately interrelated. Of course, there are many exceptions and many of the world's greatest minds have been housed in ailing bodies.

It is unfortunately true that there are many persons who are afflicted with mental disorders. As many persons are cared for in hospitals and institutions for the mentally delinquent or insane as there are in institutions for the physically sick or crippled. Part of mental deficiency is due to inheritance, part to injury or disease of the brain, skull or other parts of the body, and part to the fact that individuals do not adjust themselves adequately to the problems of social relations.

There is not yet a full or specific understanding of mental disease nor is the treatment of many mental disorders highly satisfactory. For those abnormalities that are definitely inherited it is proposed that persons who suffer from them be segregated or be sterilized by a simple surgical operation so that they cannot have children and perpetuate their kind. Segregation is too expensive to be practiced by the community. Sterilization is now being practiced in some places in a very cautious and limited way because the inheritance of mental disease is not yet fully understood.

Mental disease is frequently eliminated by treatment of physical abnormalities or defects. Alcoholism, syphilis and drug addiction represent the three most specific causes of non-inherited mental disease.

The mental delinquencies or abnormalities which are expressed in criminality, immorality, excessive irritability, inability to "get on" with people in one or more ways, despondency and other manifestations are sometimes preventable. Prevention is primarily concerned with education, particularly in the formation

Train the Child

The child, like the twig, may be inclined. With the adult, as with the tree, the task is often impossible. (From *The Growing Child*, by Dr. Hermann N. Bundesen, Chicago, 1927.)

of proper mental habits in the years of childhood and early as well as late adult life. In modern medicine certain physicians (psychiatrists) are being especially trained to help parents in the mental guidance as well as the physical care of children. Furthermore, such physicians are often useful in helping adults solve mental problems.

NUTRITION AND THE HYGIENE OF DIET

Food and Nutrition. Proper *diet* is one of the essentials of personal hygiene. The diet must be chosen with care and discretion, be adapted to the age and sex of the individual, to the season of the year and be varied from day to day or on occasion to meet the vigor and activity of the day's routine. There are a few fundamental facts which apply under all circumstances. These may be enumerated first. The starting point is an appreciation that the body is a machine whose parts are continually working. Food is the body's fuel and, as in most machines, the utilization of the fuel is accomplished by burning it in a flame of oxygen. The utilization of food depends first upon digestion (see p. 982) and then upon the oxidation of the relatively simple substances into which the food has been decomposed. The purpose of oxidation is the evolution of heat. The heat that is liberated is converted into work.

The body differs from man-made machines on two scores: (1) the combustion (oxidation) in the body is carried on at a relatively low temperature (98.6°F.) and done the less efficiently, whereas in manufactured machines the combustion occurs at high temperatures (300—2000°F.); (2) the rate at which the utilization of the food (fuel) occurs is regulated automatically by the body itself, whereas the artificial machine must be regulated by man. On the latter point the difference is more fundamental than may appear because the parts of the body repair themselves from the food. It is as though an automobile engine could replace its worn out parts by manufacturing new ones from air, oil and gasoline.

The Calorie. The operation of the body is primarily that of a "heat" machine. It uses fuel to supply heat for warmth and for energy that is to be converted into work or used in rebuilding the parts of the machine. It is therefore not surprising that the unit in which food value is measured is the same unit of heat that is used by the engineer. This unit is the *calorie*: the amount of heat that will just suffice to raise the temperature of a liter (about a quart) of water one degree Centigrade (1°C. = 1.8°F.). Thus, when it is said that one large potato or two slices of bread or three lumps of sugar contain or are equivalent to 100 calories, what is meant is that if the portion of food is completely burnt in a suitable apparatus (called a calorimeter) or is utilized in the body the heat liberated is equivalent to the amount that would raise the temperature of a liter of water from freezing to boiling temperature (from 0°C. to 100°C. or from 32°F. to 212°F.). (See color plate opposite p. 977.)

Proteins, Fats and Carbohydrates. When foods are considered in terms of their chemical composition, they are analyzed into six components. Of these the first three are proteins, fats and carbohydrates. Proteins are products of animal and plant activities and do not occur in the non-living world. They are found chiefly in meat, milk or milk products and eggs. They are very complex, chemical combinations of carbon (C), hydrogen (H), oxygen (O) and nitrogen (N). Some proteins also contain phosphorus (P) or sulphur (S). When used in the body they are first broken down by the processes of digestion to simpler substances and then rebuilt to make the structural parts of the body cells and tissues. Proteins are not conveniently used by the body as sources of energy (heat). Fats and carbohydrates (sugars, starches) are chemically compounded from carbon, hydrogen and oxygen. They are primarily energy or fuel foods but also serve in part for the preparation of the body's own tissues. Carbohydrates are especially easily burnt in the body and are therefore "quick" foods when fuel is needed, as in cold weather or during a period of severe physical exhaustion. The caloric content of these food units is approximately as follows: one gram of protein or carbohydrate will yield four calories; one gram of fat will yield nine calories. A gram is approximately one twenty-eighth of an ounce. Weight for weight, fats have more than twice the fuel value of proteins or carbohydrates. Thus, if a glass of milk contains seven grams of protein, nine grams of fat and eleven grams of sugar (carbohydrate), the fuel value can be quickly calculated:

Grams		Calories
7 (of protein)	x 4 (calories per gram) =	28
9 (of fat)	x 9 (calories per gram) =	81
11 (of sugar)	x 4 (calories per gram) =	44
	Total.....	153

We arrive at the answer that an ordinary glass of milk is equivalent to about 150

calories and two-thirds of a glass of milk represents a 100-calorie portion. Such calculations assume that foods are completely digested in the body. Experiments have demonstrated that the total food of an average mixed diet is digested with an efficiency of approximately ninety-five per cent.

Minerals (Salts). The fourth constituent of food includes a variety of mineral salts. The principal mineral elements in the body are calcium, phosphorus, sulphur, sodium, chlorine, magnesium and iron. Most of these are generally supplied in adequate quantities when food that is otherwise sufficient is eaten because practically all natural foods contain some salts. Mineral elements like calcium and phosphorus which are needed in appreciable quantities are effectively supplied by milk. Iron is also present in small concentrations in practically all foods. When selecting items in the diet it is wise to choose foods occasionally that are rich in iron. (See table on p. 1014 for iron content of common foods.) Iodine is a mineral that must be supplied to the body for the special needs of the thyroid gland. Extremely minute quantities are sufficient. Yet in some places in the world it is lacking in the water and soil and unless added to the drinking water, to the table salt or fed in suitable tablets or other form, goitre (enlarged thyroid) may be a very common disease.

Water. The fifth constituent of food is not really a food because it undergoes no chemical changes in the body and no energy can be derived from it; yet no living thing can exist without water and none of the activities of the cells can proceed without it. The largest part of the body is water, the solvent in which all of the chemical processes of life occur. The bulk of food is water. In addition to the water ingested in solid or semi-solid food the average individual needs at least six glasses of water each day.

Vitamins. In addition to the five constituents that have been mentioned the body requires in its food a sixth: minute quantites of certain substances called "vitamins." Their chemical nature has not yet been ascertained. The following table (from Winslow) lists essential facts about the principal vitamins:

VITAMINS AND THEIR OCCURRENCE

Vitamin	*Soluble in*	*Lack in Food Results in*	*Found in*
A	Fat	Lack of growth Disease of eyelids	Alfalfa, butter, cod liver oil, egg yolk, spinach
B	Water	Lack of growth Disease of nerves Beri-beri	Asparagus, beans, spinach, tomato, wheat grain, yeast
C	Water	Scurvy	Green cabbage, lemon, lettuce, orange, pineapple, raspberries, spinach, tomato
D	Fat	Rickets	Cod liver oil, fresh raw milk
E or X		Sterility	Wheat (oil of germ), hemp seed, legumes, germinated wheat germ

In recent years there has been extensive education of the public on the subject of vitamins. It is well recognized that most of the vitamins will be adequately supplied in any reasonably well chosen mixed diet that is otherwise adequate (in total calories and in the proteins, fats and carbohydrates). This is not necessarily true for Vitamin D because it occurs in significant concentration in only one common food (milk) and is destroyed by pasteurization. This vitamin is especially important for the health of growing children because it affects or regulates the formation of bones. Children must therefore be regularly given cod liver oil. The effects of Vitamin D can be duplicated by mild doses of ultra-violet rays. Summer sunlight is ordinarily sufficiently rich in these rays to meet all ordinary requirements. In the late autumn, winter and early spring sunlight may not contain sufficient ultra-violet rays to prevent rickets. In these seasons of the year the regular use of cod liver oil or some artificial source of ultra-violet rays is doubly important for children. When using sunlight as a source of ultra-violet it must be constantly kept in mind that these rays do not pass through ordinary window glass. The child that is to be protected against rickets by treatment with sunlight must therefore be placed in the direct path of the rays in the open or, if in the house, near an open window.

It appears at this time (1931) that the power of ultra-violet rays to prevent rickets can be more or less permanently stored in certain substances. There is a particular substance, *ergosterol* or *viosterol* which can be treated with these rays (irradiated) and which when taken by mouth in very small doses is effective in preventing rickets.

Total Food Needs of the Body. It is evident from what was said above that the amount of energy which must be supplied the body in the form of food must balance the amount of energy that is being used each day. The food must supply the energy for body work and the constituents from which new tissues are made. The body of a young baby is not burning many calories for energy but it is utilizing food that is equivalent to many calories for the building of new bone, muscle, blood and so forth. The body of a full grown adult needs no food for tissue growth: it requires food only to replace tissues that are breaking down and to supply energy for work. In the body of the growing child food is being stored and the intake of foods exceeds the output of wastes. In an old person the converse occurs, tissue is being destroyed in the body more rapidly than it is being repaired and the output exceeds the intake. The following table of figures compiled by Gillett and taken from *Chemistry of Food and Nutrition* by Professor Henry C. Sherman indicates the total food requirements of young persons each day:

FOOD ALLOWANCES FOR HEALTHY CHILDREN

Age Years	*Calories per Day*	
	Boys	*Girls*
Under 2	900-1,200	900-1,200
2-3	1,000-1,300	980-1,280
3-4	1,100-1,400	1,060-1,360
4-5	1,200-1,500	1,140-1,440
5-6	1,300-1,600	1,220-1,520
6-7	1,400-1,700	1,300-1,600
7-8	1,500-1,800	1,380-1,680
8-9	1,600-1,900	1,460-1,760
9-10	1,700-2,000	1,550-1,850
10-11	1,900-2,200	1,650-1,950
11-12	2,100-2,400	1,750-2,050
12-13	2,300-2,700	1,850-2,150
13-14	2,500-2,900	1,950-2,250
14-15	2,600-3,100	2,050-2,350
15-16	2,700-3,300	2,150-2,450
16-17	2,800-4,000	2,250-2,600

It will be noted that boys require more food than girls and that the requirements increase from 900-1,200 calories for the infant to 2,250-4,000 calories for sixteen to seventeen year old girls and boys. The average adult requires about 2,700-3,500 calories each day, more or less, depending upon the activity of the individual. The following quotations from Professor Graham Lusk (*The Science of Nutrition*, Third Edition) illustrates how much the food requirement of the adult varies with occupation:

> A seamstress sewing with a needle required 1,800 calories.
>
> Two seamstresses, using a sewing machine, required 1,900 and 2,100 calories, respectively.
>
> Two bookbinders required 1,900 and 2,100 calories.
>
> Two household servants, employed in such occupations as cleaning windows and floors, scouring knives, forks and spoons, scouring copper and iron pots, required 2,300 to 2,900 calories.
>
> Two washerwomen, the same servants as the last named, required 2,600 and 3,400 calories in the fulfilment of their daily work.
>
> Concerning the fuel requirement for the occupations of men:
>
> Two tailors required 2,400 to 2,500 calories.
>
> A bookbinder required 2,700 and a shoemaker 2,800.
>
> Two metal workers, filing and hammering metals, required 3,100 and 3,200.
>
> Two painters, occupied in painting furniture, required 3,200 and 3,300 calories, and two carpenters engaged in making tables required the same amount of energy.
>
> Two stonemasons chiseling a tombstone needed 4,300 and 4,700 calories.
>
> Two men sawing wood required 5,000 and 5,400 calories.
>
> The proverbial reputation of sawing wood as a strenuous occupation has here its scientific verification and explains the disinclination of the hungry to engage in this useful occupation, as well as the unpopularity of charitable wood yards.

Kinds of Food Needed: It is not sufficient that the diet should include the requisite

number of calories. It is necessary that they be provided in suitable proportions among the proteins, carbohydrates and fats. It has become the fashion for most people to eat too much sugar in concentrated form. Most persons may be better off for less sugar with or between meals. It is generally admitted that hunger and appetite are reasonably safe guides to the amount of food consumed. If in addition the adult individual recognizes that when he is increasing in weight and getting fat his food contains more energy than he needs and if he is losing weight and is getting thin it contains too little. After reaching maturity the weight remains approximately constant. The results of many studies indicate that the average adult uses each day from 2,700 to 3,500 calories of which approximately 400 are derived from protein. It appears from recent investigations that it matters relatively little what proportion of the total calories are derived from fats. If for any considerable period too little fat is eaten the individual soon feels a little hungry after a meal even though the food eaten is sufficient in total nutritional value. If it were necessary to make a single estimate of the proportions, it might be said that ninety to 115 grams of protein, fifty to sixty grams of fat and 500 grams of carbohydrate (the total equal to about 3,000 calories) is not far from the needs of an average adult man doing moderately vigorous muscular work. A woman would need about three-quarters as much of each item. Changes in body weight should provide the index to needs for increase or decrease in the total caloric intake. In general, the protein intake should not be reduced below ninety grams per day and may be increased to 125 to 150 grams for persons doing very vigorous exercise or work.

Roughage. In addition to an adequate number of calories and proper proportions among the several kinds of essential foods, the diet should have bulk and should contain some indigestible matter. The purpose is to supply "roughage" because the presence in the digestive tract of food that has "body" or bulk stimulates the intestines to active peristalsis (see p. 982). The food is then moved along more rapidly and more effectively, elimination of wastes is hastened and the bowel movements are more regular. The cellulose in vegetables and fruits is indigestible and is the most valuable, regular source of roughage in the diet. It is desirable to include at least one green, leafy vegetable in each day's food to supply roughage (as well as vitamins and minerals). Many fruits such as apples, figs and dates are slightly laxative for most persons and may be used liberally in the diet by those who have sluggish bowels.

A physician should be consulted if constipation recurs frequently or persists when sufficient water, milk or other fluid is consumed, the diet contains ample bulk and roughage and regular exercise is taken. Self-medication is dangerous because it may result in the establishment of a "lazy" intestine or because some abnormal condition that requires attention may be seriously neglected.

Preparation of Foods. An important part of the hygiene of diet is that food be properly prepared and attractively served. The sight and smell of good food stimulates the saliva to flow. Experiments have shown that other digestive juices are also secreted under the influence of such stimuli. The time and energy that go into the careful preparation of food are contributions towards good digestion. Warmth of food is another factor that aids digestion so that it is advisable to have at least one warm dish in each meal, except in very warm weather when cold foods are more pleasurable to eat.

Fruits and vegetables which are eaten raw should be thoroughly washed before they are served. In addition to destroying microbes, cooking makes many foods more tender because heat breaks down such things as the cellulose walls and fibers in vegetables and softens the muscle fibers in meats. The food is then more easily chewed and more effectively penetrated by digestive juices. Foods that are sautéd, fried or cooked in deep fat are often difficult to digest and should not make up more than a small fraction of the diet.

It is important to remember that vegetables should be cooked with a minimum of water. The less water used, the less loss there is of vitamins and minerals in the water that is often discarded. It is good practice to use the cooking water from vegetables in soups, gravies and sauces.

A word of caution may be said about the choice of cooking utensils. Earthenware and glass are most desirable because they are highly insoluble. Of metalwares, copper and brass are most objectionable unless lined with tin. Iron, nickel, tin and aluminum vessels are least objectionable. Enameled pots and pans may be used provided the glaze does not contain lead.

TYPES OF DISEASE AND THEIR CAUSES

Health and Disease. It will be recalled that the body of a living thing passes through many changes during its span of life. This is true of all living things, whether plant, animal or human. Each goes through a cycle: conception, growth, differentiation of various parts and specialization of their functions, maturity, reproduction, old age and decline, and finally death. All of these are normal processes through which complex organisms pass. Health, we have said, is the normal working of the living body. Therefore it follows that death, as well as life, is normal, and is part of "health" itself. The term "disease" must be restricted to the failure of one or more parts of the body to function, or to their abnormal functioning. The breakdown of a part may remain local and restricted, or it may lead to the failure of other parts. This, in turn, may go further and further until the maintenance of balance, work and repair of the whole body become impossible.

Origin of Disease. The beginning of disease may be due to *internal* or to *external* causes. An example of an internal injury is the rupture of the appendix, the bursting of a blood vessel which has lost its elasticity, or the failure of some part to function because it is not receiving its necessary fuel (food) or is not disposing of its wastes. Diseases which follow injuries of the last-named kind are commonly called *nutritional*. Of the diseases of external origin, the simplest to consider are those which follow upon *mechanical* injury, as by crushing, cutting, tearing, burning, shooting; or upon *chemical* injury, as from corrosive acids, alkalies, drugs, or other substances. The injury done by a mechanical or chemical cause is usually called *trauma*, and is spoken of as *traumatic disease*. Among the diseases of external origin, the commonest, most widespread and most important are those due, not to mechanical or chemical, but to *biological*, causes. They are due to the direct or indirect action of living things, large or small, living on or in the body of the plant, animal or human as the case may be. Disease is also divided into: (1) *intrinsic*, or constitutional causes, and (2) *extrinsic*, or environmental causes.

MICROBES AND VECTORS OF DISEASE

Parasitism. Many will recall the famous lines of Swift:

> So, naturalists observe, a flea
> Has smaller fleas that on him prey;
> And these have smaller still to bite 'em.
> And so proceed *ad infinitum*.

Of this passage, the following is a more popular version:

> Big bugs have little bugs
> Upon their backs to bite 'em;
> And little bugs have lesser bugs,
> And so *ad infinitum*.

The condition of one living thing living on another is extremely common and prevalent throughout the organic world. In an indirect way, the dependency of one group of organisms living upon other groups is part of the whole scheme of the living world, as will be described later ("The Cycle of Foods in Nature," p. 998). Many living things have become adapted to obtaining part or all of their food, warmth or other requirements from other living things. The mistletoe that lives as a sucking vine on a larger tree, the mold on a leaf, the insect piercing the skin of an animal for a meal of blood—each attests how widespread is the occurrence of parasitism. The word "parasite" has an interesting origin which is descriptive of the process to which it is applied. It was first applied to the person who sat at the table of another and ate at his expense (from the Greek words, *para* and *sitos*, meaning "to eat beside"), and only recently came to be applied to plants and animals. The comparison may be carried further: Even as the human parasite—minstrel, jester or other—came to be dependent upon his host, in many instances, so also has the plant or animal parasite become incapable of supporting itself without a living host. The fact that we still speak not only of a "parasite" but also of its "host," is reminiscent of the origin of the term parasite.

A parasite may live upon its host and do comparatively little damage, so that the two may live together without serious abbreviation of the host's span of life. In the case of microbes which live in the nodules that may be seen on the root-hairs of a pea, bean or clover plant, not only is the parasite harmless to the host, it is even beneficial because the microbes change certain substances in the soil so that the plant is enabled to use them as foods. One might with equal force say that the leguminous plant is the parasite on

the microbes which it harbors in its root-hair nodules. But not all parasites are so harmless. More generally, they deprive the host of food needed for its own purposes or interfere with its own nutrition. If they are in, and not merely on, the host, they may injure or interfere with the function of tissues or even organs so that the death of the host may ensue. Injury which is caused by the presence, growth and multiplication of parasites, and by the action of poisonous substances which they produce, is said to be *infectious* disease. The parasitic causes of most, but not all, infectious diseases may be transferred from one host to another. Infectious disease may be *communicable*. If the communication from one host to another is usually accomplished by more or less direct contact between the infected and the non-infected, potential host, the communicable disease is said to be *contagious*.

Communicable diseases are responsible for a large proportion of all sickness, and they are the cause of at least two-thirds of all premature deaths. For this reason it is especially easy to understand of what tremendous importance have been the discoveries concerning parasitism. From these discoveries have flowed humanitarian accomplishments which are exceeded by those of no other branch of natural science; and in their effects upon the health and well-being of man, they are without peer. What some of these discoveries are, how they came about and how they are applied, will appear clearly later. They have enabled man to control disease to such an extent that human beings can congregate in cities safely without being wiped out by epidemics of communicable disease.

Important Kinds of Parasites of Man. There are so many different kinds of living things which live as parasites upon other living things, that we cannot undertake to discuss them all. We must restrict our attention to those which are parasites on human beings—and to only the most important of these.

It is an interesting fact that practically all of the important communicable diseases of man are caused by parasites which are so small that, as individuals, they cannot be seen by the unaided, human eye. For this reason they are called "microbes" (from the Greek words: *mikro*, "small" and *bios*, "life"). All but a few of them can be seen when examined through a microscope which is capable of magnifying an object as much as a thousand or two thousand times its natural size.

The most important microbic parasites of man are not only very small, but they are single living cells. When one grows to mature size, it divides into two or more cells which usually separate from one another, and each new cell lives an independent life. Certain of the unicellular microbes have chemical composition, food requirements, methods of growing and dividing which place them in the plant kingdom. These are called *bacteria*. Others are more closely allied to the animal kingdom, and are known as the *protozoa*. There are many multicellular microbic parasites, some plant, like the *molds*, others animal, like the *worms*. Some of these parasites may be spread from person to person by contact. Others gain access to the human body in dirt, dust, saliva or sputum, through the skin in cuts, abrasions or wounds, or by way of the mouth or nose. We can consider these matters more specifically later when discussing particular parasites and the diseases they cause. Let us first consider the *Protozoa* briefly, and the *Bacteria* in more detail, so that we can understand what they are, how they behave and how man has learned to conquer them. The general principles learned from the study of bacteria will apply to the other forms, with such exceptions as will be specifically noted.

The Protozoa. The Protozoa are single-celled microörganisms which, because of their composition, structure, methods of reproduction, food requirements, and other characteristics, are placed at the foot of the animal kingdom, as the bacteria are placed at the foot of the plant kingdom. Because there are a number of important diseases of man caused by protozoan parasites, they deserve mention here.

A Protozoan Parasite
The protozoan parasite (trypanosome) of sleeping sickness.

Those of us who live in the temperate climates of the world are fortunately spared from many of these plagues, because they are more or less definitely restricted to tropical areas. Malaria and amebic dysentery are the only protozoan diseases that need to be discussed in this chapter, for they are world-wide in their occurrence, and are widespread in the United States. The parasites of these two diseases are described elsewhere.

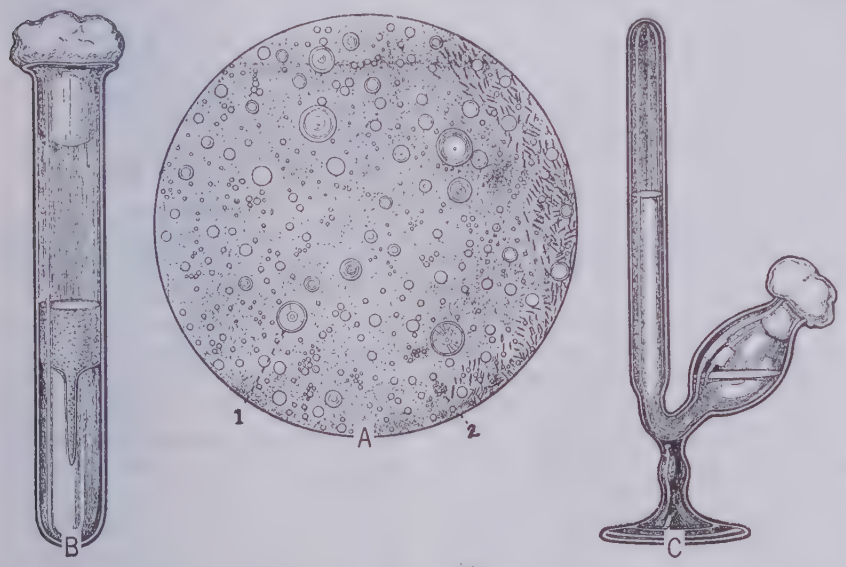
The Size and Growth of Bacteria. There are more bacteria in the world than all other living things combined. Yet because they are so small, only a few of the earth's billions of people who have contact with them every day have ever seen them. An average sized bacterium is so small that it would take some fifty million to make a lump the size of a grain of sugar, and a drop of water no larger than a raindrop could hold about a thousand million. Bacteria are so small that, for the sake of convenience, a special unit of length is used to describe their size. This is the "micron," commonly expressed by the Greek letter *mu* (μ), which is $\frac{1}{1000}$ of a centimeter, or $\frac{1}{25000}$ of an inch. Average sized bacteria may be from one to ten μ long, or wide, or thick.

The following is a brief table of bacterial dimensions:

	micra
Bacterium coli	0.5 by 1.0-2.0
Bacterium typhosum	0.6-0.8 by 1.0-1.5
Bacillus tetani	0.4-0 6 by 4.0-8.0
Staphylococcus aureus	0.8-1.0
Streptococcus lacticus	0.6-1.0
Vibrio cholerae	0.4 by 2.0

Each bacterium, despite its small dimensions, and although it is a single cell, is an extremely complex living thing. What bacteria lack in size, they make up in activity. The reason for this is that the speed at which organisms live, other things being equal, depends upon the ratio of their surface to their volume or bulk. All things of simple shape have larger surfaces for their volume the smaller they are. For example, a sphere with a radius of one inch has a surface (in square inches) which is only three times its volume (in cubic inches); but for a sphere with a radius of one-tenth of an inch, the surface is thirty times its volume, and for still smaller spheres the ratio of surface to volume is proportionately greater. A man of average size may have a half of a square inch of body surface for every cubic inch of volume. A bacterium of average size may have 50,000 times as large a surface for its own volume. Each living cell, whether bacterium or tissue cell, must obtain its food from the fluid in which it is bathed and must excrete its waste products into this fluid. The more surface it has the more rapidly and the more efficiently it can take in foods and give off its wastes. Under proper conditions of temperature and food supply, each bacterium may grow into two, every twenty minutes. It may be calculated that from a single bacterium, a billion could be produced in ten hours; and enough to fill the ocean, in a few days. But such rapid multiplication never actually occurs except for a brief period of time because their food gives out, because products of the digestion of food stop their activities and because they have enemies which eat and destroy them. Nevertheless, it is very important to remember how rapidly bacteria can (and do) live and multiply; otherwise it may be difficult to understand how they do so much damage in a short time when they get into the body.

Bacteria Everywhere in Nature. It is almost accurate to say that bacteria are present everywhere. There are a few in every breath of air we draw. They are in the water we drink and in the food we eat. There may be thousands in a speck of dust or dirt. They are in the soil and on the leaves, stems, fruits, flowers and seeds of plants. There are millions of them on the skin and in the mouth and intestines.



Good and Bad Bacteria. It is fortunate for man that not all bacteria are parasites. Indeed, most kinds are entirely unable to live in or on man, animals or plants. Not only are they harmless, but many are actually very useful to man. There are several thousand kinds of bacteria known, but only forty or fifty kinds are parasites that cause disease. If some are good and others bad, it is obviously important to know how to tell one kind from another.

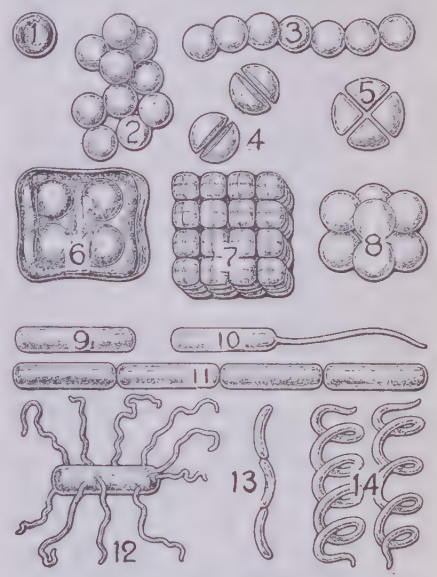
Kinds of Bacteria. Biologists ordinarily develop their systems of identifying living things by considering the shapes, forms and sizes. They set those which are similar together, and those which are different, apart.

That is, the first principle of classification is *morphology* (the study of form). Bacteria are all very small, they differ little in size and they show only limited structural differentiation. Hence, morphology provides only a beginning for a system of classification.

When bacteria are examined with a suitable microscope, three general shapes are seen: sphere, rod and spiral. These are called *coccus*, *bacillus* and *spirillum* (plurals: *cocci*, *bacilli* and *spirilla*), respectively. Each is a single cell with no particular differentiation of parts within it. It is still uncertain whether the bacterial cell has a true cell wall or a separate nucleus. There is no doubt, however, that the surface has the properties that are usually associated with a cell wall, and that there is nuclear material scattered more or less throughout the cell. Special kinds of pigment particles, food and other kinds of granules and vacuoles are usually present. In many bacteria the presence of pigment or granules occurs regularly and is useful in identifying them as belonging to only for bacilli and spirilla. Not all—only about half—the members of the two latter groups have flagella, and some species have one, some two or more. Some have them at one end, some at both ends and some all around the cell, as may be noted in the illustration.

Spores. Some species of bacilli have the ability to change their normal rod-like shape (termed the "vegetative" state) to a more condensed, spherical body called a *spore*. This change usually occurs when conditions are not favorable, as when the temperature is too high or too low, when food gives out, or when acids, alkalies or other products of digestion accumulate. In the spore stage, the cell is not easily penetrated by injurious substances and is very resistant to heat. Thus it is generally true that bacteria in the vegetative state are killed in a few seconds at the temperature of boiling water, and in a few minutes in hot water. But spores may survive boiling for half an hour, and some have been known to survive as long as

Growth of Bacteria



Many methods are used to cultivate bacteria and other microbes. A plate culture is a shallow dish containing a culture medium—a jelly which includes foods for the microbes. Each microbe which grows in or upon the jelly may multiply into so many that a visible colony of microbes develops. The plate culture (A) contains many such colonies of molds, yeasts and bacteria. In the tube (B) there was jellied culture medium into which was stabbed a platinum needle that had first been sterilized and then touched to a colony of bacteria. Where the needle passed, bacteria were left in the medium. They have grown and liquefied the jelly, especially near the surface where air is plentiful. The tube (C) is a fermentation tube. The closed arm had been filled with a sugar medium and then inoculated with microbes. They have fermented the sugar and produced gas. As the gas bubbles rise through the fluid they are trapped in the closed arm and provide direct evidence that the sugar has been fermented.

some particular genus or species. Bacteria may be further divided according to the kinds of groups in which they tend to stay.

Motion of Bacteria. Some bacteria have whip-like appendages called *flagella*. By lashing these to and fro in water or some other fluid, the cell may be given a motion which may reach quite a considerable speed. An actively motile bacterium may move twenty-five times its own length in a second. This speed is five times greater than that of a champion human runner. Flagella cannot be seen on the ordinary bacterium but are made visible by staining with a dye. Up to this time (1931), there have been no authentic discoveries of cocci with flagella, these organs of motility having been demonstrated

sixteen hours. It is a fortunate fact that there are extremely few disease bacteria that can form spores. Otherwise it would be extremely difficult for man to protect himself against these microbes. Botulism, which is one kind of food poisoning, tetanus, which is lockjaw from infection of a wound, and anthrax are the only important diseases caused by spore-forming bacteria.

Chemical Tests for Bacteria. Although bacteria are of three different shapes and vary in size and certain details of form, they can be easily divided into general classes. There are many which, though they look very similar when seen through the microscope, are different. Many simple and complicated chemical tests must be used to tell one from another. For example, the harmless *Bacillus coli*, which is present in large numbers in the intestines of man and other animals, looks just like the dangerous microbe of typhoid fever, *Bacillus typhosus*. They can be distinguished by placing them in separate tubes of broth (a special kind of soup in which bacteria grow and multiply) to which glucose or grape sugar has been added. In glucose

Common Bacteria

The structure of the common kinds of bacteria as seen under the microscope: 1. Coccus; 2. Staphylococcus; 3. Streptococcus; 4. Diplococcus; 5. Tetracoccus; 6. Tetragenous form; 7. Sacrina lutea; 8. Eight cell group of cocci; 9. Bacillus; 10. Bacillus with flagellum (monotrichous type); 11. Streptobacillus; 12. Peritrichous arrangement of the flagella; 13. Vibrio; 14. Spirilla.

broth, both species use the sugar as a food and will produce acid, but *B. coli* will also produce gas, whereas *B. typhosus* will not. If they are placed in separate tubes of broth containing lactose or milk sugar instead of glucose, *B. coli* will use this sugar, too, and will produce acid and gas; but *B. typhosus* will not use the sugar at all, and neither acid nor gas will be formed. By using many kinds of sugars and other substances, chemical differences are detected among bacteria which are alike or similar in shape, form, size and motility. When it is necessary to identify bacteria, as in the diagnosis of infectious disease, material taken from the patient is examined directly, or the bacteria in it are first grown on broth or other food and then studied with the microscope or by various chemical tests according to the disease which is suspected. The invention of methods for making these tests quickly is one of the great contributions of bacteriology. For many diseases the diagnosis can be made speedily and accurately, and the steps necessary to treat the patient and to prevent the spread of the disease to other persons can be taken promptly.

Bacteria in Air. The air near the surface of the earth usually contains bacteria, yeasts, molds and other microbes. These are usually present on dust particles, so that in general the more dust, the more microbes in the air. Country air usually contains fewer microbes

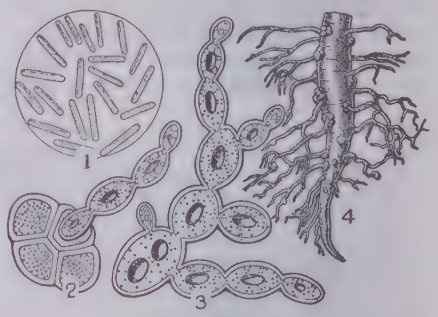
than city air, and the air on a mountain or up high where a balloon or an airplane may go, may be practically free from dust and microbes.

The air in an ordinary city street or in a schoolroom may contain a thousand microbes per cubic foot. There may be many more where dust is being raised or in the air near a person who is sneezing or coughing. The important thing is not how many bacteria there are in the air, but what kinds there are. Those ordinarily present in the air we breathe are harmless and unimportant. But when the air is being contaminated by a careless person who sneezes or coughs, in the droplets which are sprayed from his nose or mouth there may be dangerous disease germs. When air containing these droplets is breathed, disease may follow. It is well known that colds, pneumonia, scarlet fever, measles, tuberculosis of the lungs (consumption) and many other diseases are spread in this way. HUMAN BEINGS, NOT THINGS AROUND THEM, ARE THE USUAL AND COMMON SOURCE OF INFECTIOUS DISEASE.

Bacteria in Water. The water in brooks, streams, rivers, wells, ponds and lakes may contain the same kinds of bacteria which occur in air, soil, or dust. When the rain falls, it washes bacteria with it wherever it drains. These bacteria are not ordinarily dangerous or harmful. They are called the normal bacteria of water.

The importance of pure water for drinking and cooking purposes was known to man in ancient times, and he knew that filthy, dirty or smelly water is not safe to drink. It was not until about a hundred years ago, however, that it was clearly understood that even water which may look pure and wholesome may contain disease-causing substances. Even long before bacteria were known to be the specific causes of certain infections, it had been proven that typhoid fever, cholera and dysentery were usually contracted from water which contained excreta of persons sick with these diseases. The protection and safeguarding of a private or public water supply require that every precaution be taken to avoid the entrance of sewage or other human wastes; because the germs of dangerous intestinal diseases are commonly present in large numbers in excreta.

Bacteria in Soil. The surface of the earth is rich in bacteria and other microörganisms. This is particularly true of fertilized soil. There may be many millions in an ounce of soil within an inch or two of the surface. The deeper one goes the fewer there are, and two or three feet below the surface the soil may be sterile, particularly if it has not been recently turned or disturbed.



Soil, like air and water, contains its own normal kinds of molds, yeasts, protozoa and other microbes. These are usually non-parasitic kinds which are not concerned with questions of human health and disease. In many places, however, the soil contains certain bacilli which are capable of causing infections. There are two important dangerous kinds which may occur in the soil. The first, *Bacillus tetani*, is a spore-forming, rod-shaped bacterium which grows only where there is no air or oxygen. It is an *anaërobic* organism, this name meaning that it is an organism which lives without air. When dirt containing this organism or its spore gains entrance to a deep cut, scratch or wound, it grows and produces a substance (a toxin) which is extremely poisonous to nerve tissues and causes the disease called *tetanus* or *lockjaw*. To prevent this disease, wounds into which soil or dirt has entered must be thoroughly cleaned and disinfected. If the injury is a serious one, and dirt has surely got in, the wound must be treated by a physician and the patient must, in addition, be injected with tetanus antitoxin. In the early days of the World War, because the fighting was so largely in trenches which had been dug in highly fertilized soil, many lives were lost from tetanus because shrapnel and shells usually carried bits of soil into the wound. Later the practice was established of giving each seriously wounded person a suitable dose of tetanus antitoxin to prevent the occurrence of the disease.

The second dangerous bacterium which may be present in soil is *Bacillus botulinus*. This is also a spore-forming, anaërobic organism. It is not known to be infectious in wounds or if swallowed. If it gains entrance to food and this is left in a warm place, the bacillus may grow and produce a toxin which is extremely deadly to anyone who eats the food. The spore of this organism is quite resistant to heat and may survive all but the most thorough cooking. It is particularly dangerous in food that has been improperly canned. The fact that *B. botulinus* is an anaërobe provides the first factor of safety to man, because the bacillus cannot grow or produce toxin if it is in anything that is exposed to air. The second factor of safety is that the toxin which is produced is easily destroyed by boiling the food. Any food which might have been contaminated with soil from the garden, and which has been kept for some time in a closed container in a warm place, should be thoroughly cooked before being eaten. So far as it is now known, cooking must be sufficient to destroy the toxin. It is apparently less important whether the organism or its spores have been killed.

Cycle of Foods in Nature. Very little more needs to be said about the non-parasitic bacteria in soil, or about the specific disease germs that might be there. But there are other groups of bacteria, and other microbes, whose regular presence in soil has a significance so great that it must be mentioned here. These are the bacteria which act on organic matter—like the dead bodies of animals and plants—and bring about their rotting and decay. The stuff of which bodies, leaves and twigs are made are thereby converted into simpler and more soluble substances which dissolve into the earth and can be used again by plants as food-stuffs for growth. Plants, in turn, are eaten by animals and man; animals are eaten by man; and plants, animals and man (when they are dead) are, in turn, decayed by microbes and returned to the soil. In this never-ending cycle of the elements in nature, bacteria play an essential rôle. Without their aid, the earth's surface would soon become cluttered with the unchanging material of dead plant and animal life. Growing plants would soon exhaust the soil of food materials, and both plants and animal life would come to an end. Man cannot live without certain kinds of microbes, and he must beware of how he lives with others.

Dirt and Bacteria. A word more might be said about "dirt," because of the widespread fear of it. Dirt, in itself, holds no danger to man. It is not the rust which makes the wound from a rusty nail dangerous; a rusty nail usually has dirt on it, and when there is dirt there usually are microbes. It is the microbes, not the dirt or the rust, that counts. Similarly, the mere presence of dirt in food introduces no special danger. It is of more concern how many and what kinds of microbes go with the dirt.

Bacteria in Milk. Milk is a fluid which is manufactured by the mammary glands of the female of all mammals. It is intended for the

Helpful Microbes

A few kinds of beneficial germs (1, 2 and 3 as seen through the microscope): 1. Lactic acid bacilli; 2. Yeast growing out of an ascospore; 3. Yeast budding; 4. Nitrogen fixing bacteria in nodules on roots of legumes.

feeding of the baby animal from birth until the young can digest other foods. Milk is the sole food of the young animal, and contains all the substances necessary for a complete diet. It is therefore not surprising that milk, which is sometimes called "Nature's perfect food," will serve as food for bacteria. After centuries of experimentation, man has learned how to domesticate the cow and breed it for beef and milk. Cow's milk has become an important item in the human diet. Practically all common species of bacteria will thrive in the milk of cows or other animals. The rate at which they grow and multiply in milk depends almost entirely on the temperature. They grow slowly or not at all in very cold milk; more rapidly the higher the temperature up to body heat (98.6° Fahrenheit or 37.5° Centigrade), and at higher temperatures they are killed more rapidly than they can multiply. No matter how carefully obtained, milk always contains some bacteria. The large majority of the bacteria present in fresh milk come from dust and dirt on the cow in the dairy barn, on the hands of the milker, in the utensils or from other sources. The number that are present in a given sample of milk depends upon the number that were present when it was freshly drawn, upon its age and the temperature at which it has been kept. Milk that is carefully collected into clean vessels and with due precaution to keep dirt out may contain a few hundred to a few thousand bacteria in a cubic centimeter. If it is promptly chilled and kept cold, the number may remain for many hours or days under 10,000 or 50,000

in a cubic centimeter. If the milk is not cooled, after from twelve to twenty-four hours there may be millions, hundreds of millions or even billions in a cubic centimeter.

When bacteria grow in milk they use the proteins, fats and sugars of the milk as foods, and they produce waste products. From the lactose (milk sugar), the common milk bacteria produce lactic acid and other substances which result in an acid or sour taste, and which clot or curdle the milk. This is the common "souring," or fermentation, of milk. So long as the kinds of bacteria in milk are those which tend merely to sour it, no serious danger occurs. Sour milk with its many millions of bacteria is a safe food, for the bacteria are harmless or even beneficial. If the bacteria present in the milk happen

Harmful Bacteria

A few disease-producing (pathogenic) types of bacteria: 1. Typhoid fever; 2. Tuberculosis; 3. Boils, etc.; 4. Diphtheria; 5. Asiatic cholera; 6. Tetanus (bacilli with and without spores).

to be of certain other kinds then, instead of souring it, they may rot or putrefy it. The milk then has a foul taste and smell, and is unfit for consumption. Furthermore, if disease germs find their way into milk from the udder of a sick cow, from the milker, or from persons associated with milk production and distribution, and if these microbes have an opportunity to increase in numbers, serious consequences usually follow to the consumer. Milk may contain many millions of harmless or harmful bacteria, in spite of the fact that it may look fresh and clean. (The methods which are used to protect the milk supply are described on page 1009).

Bacteria and Disease. The ways in which bacteria act to cause disease have already been touched upon. Briefly, we may say they produce injury in two ways: (1) As the bacteria live in tissues, they destroy them by using them as foods and by the injury that is done by the acids and other substances produced as waste products of bacterial digestion; (2) They produce substances called *toxins* which are extremely poisonous to the tissues and organs of the host. Injury of the first type is usually local in character, although it may become generalized in the body as the bacteria are carried from part to part by the blood or lymph. Injury of the second type is also usually local, not because the bacteria are localized, but because each particular toxin has its own special damaging powers: for example, the toxin of the bacillus of botulism acts chiefly on certain nerves; that of the tetanus bacillus, on other nerves; the toxin of the dysentery bacillus, on the intestines; the toxin of the diphtheria bacillus, on the heart and other organs. So far as is now known, only a few species of bacteria that are *pathogenic* (disease producing) for man produce true toxins. In most cases, injury is of the first type described above, although it is being discovered, for an increasing number of disease bacteria that they can produce toxins. Many disease bacteria are like the diphtheria bacillus in that they may not have great powers to penetrate tissues, but may do their damage locally or at a distance through the action of the soluble poisons (toxins) which they secrete. It is not yet understood why germs and their poisons have specific affinities for particular tissues, but these affinities are very high. Indeed, it is this type of property which results in the special characteristics of each disease, the signs and symptoms depending upon which tissue is injured and upon the particular way in which the injury is produced.

INFECTION AND RESISTANCE

Natural Defense Against Bacteria. Considering the widespread occurrence of bacteria and other microbes in the environment, it may seem surprising to many that man and other complex living things survive at all in a world which harbors so many potential and actual enemies. Nor would man survive if it were not for the effective, natural defenses with which he is equipped, and for the artificial bulwarks which he has learned to utilize.

We shall now mention some of the natural defenses against the invasion of the body by microscopical or other enemies. (1) There is the skin and the mechanisms by which it maintains its integrity. The unbroken skin is, in effect, a protective layer or shell around the outer parts of the body; and, being a living tissue, it regenerates itself continuously unless it is too extensively injured. Although there are a few unusual exceptions, the general rule is that bacteria do not ordinarily penetrate the unbroken skin. (2) Another defense is the effective protection provided by the intact and healthy mucous membranes of the mouth, throat, nose, lungs, stomach, intestines, bladder and other organs. (3) The strongly acid nature of the secretion of the stomach glands is undoubtedly responsible for the destruction of enormous numbers of microbes that are ingested with food and drink. (4) Many fluids in the body have mild or strong antiseptic or germicidal properties. This is notably true of the blood, and inasmuch as the blood reaches all parts of the body, a considerable degree of protection is afforded all tissues. The flowing lymph, the fluids between cells and the secretions of mucus glands have mild antiseptic or germicidal properties. Such a fluid as the lachrymal gland secretion which bathes the eye has a distinct antiseptic property. This is one of the reasons why injuries of the eye only infrequently lead to infection, and why operations on the eye can commonly be performed without an antiseptic or disinfectant. (5) The white cells, or leukocytes, in the circulating blood have the power to engulf bacteria and many other kinds of foreign particles; and in many cases they can destroy the engulfed material. When cells take up foreign particles the process is called *phagocytosis*, and the cell which performs it is a *phagocyte*. In addition to the wandering phagocytes, such as are exemplified in the leukocytes of the blood, there are fixed tissue phagocytes in the spleen, liver, lymph glands and numerous other organs. In general it may be said that in the diseases in which injury is done by the microbe rather than by a toxin, the phagocytes provide the principal internal defense mechanism of the body. Anything which increases the powers of the phagocytes makes for increased immunity, and anything which weakens their powers makes for increased susceptibility to disease. (6) The body frequently utilizes its power to wall off a parasite by laying down an impermeable layer around the affected area. This is one of the most important methods of defense against the germ of tuberculosis.

The natural defenses that have been mentioned vary in efficiency in animals of different kinds, among animals of a particular kind and among humans. Furthermore, some are more important against one parasite and others against another. The effectiveness of all combined goes to make up what is known as the *natural immunity* of the living thing against parasites. This is determined by inheritance. It may increase or decrease with age.

Acquired Immunity. In addition to the natural immunity, each individual may acquire an increased immunity as a result of one or more of a variety of processes. The commonest form is the increased resistance against infectious disease which results from an attack of the disease itself. This is called *naturally acquired immunity*. Even primitive man knew that an individual usually never has this or that disease again after having once recovered from an attack of it. Today most people know that it is rare or unusual for an individual to have measles, scarlet fever, diphtheria or smallpox a second time. One attack of the disease has left the body with a new and increased capacity to resist the infecting agent, so that the individual may go unharmed even though highly exposed to infection by contact with persons who have the disease.

Antitoxins. How does a first attack of infection render the body protected against a second, and why is the protection specific for the particular disease? From the results of many brilliant investigations the answer is partly known. It will be recalled that diphtheria is due to the toxin secreted by the diphtheria bacillus. It is now established that the toxin stimulates the tissues of the body to produce a new property in the blood,

a property of neutralizing the poisonous qualities of the toxin. This new property is said to be *antitoxic* and is supposedly due to the presence of an *antitoxin* in the blood, although scientists have not yet succeeded in discovering just what antitoxin is. Furthermore, this antitoxin will neutralize only diphtheria toxin and no other. ANTITOXIN IS SPECIFIC FOR THE TOXIN WHICH CAUSED ITS PRODUCTION IN THE BODY. Just as the toxin of the diphtheria bacillus stimulates the body to produce diphtheria antitoxin, the toxin of the tetanus bacillus arouses the production of tetanus antitoxin, and so on down the list of the toxin diseases. By many experiments we have come to understand the mechanism of naturally acquired immunity against toxin-producing parasites. Such a substance as antitoxin is called an *antibody*.

Antibodies. There is reason to believe at this time that most infectious diseases are not due to toxins. If there are no toxins, there can be no antitoxins. How, then, does the body become immune after an attack of such disease? The answer is that the microbe and its products arouse the body to produce in the blood and tissues certain new properties of defense against the microbe itself. These are said to be due to various kinds of antibodies, each being named according to the way in which it acts. Thus, a person who has had an attack of typhoid fever is usually immune against this disease during the remainder of his life. There is no sound evidence that the typhoid bacillus produces a toxin, nor that the immunity acquired naturally by an attack of the disease is due to the appearance of an antitoxin in the blood. It is not difficult to show, however, that the blood of the immune person will cause the clumping, or *agglutination*, of typhoid bacilli much more effectively than will the blood of a person who has not had the disease and who is not immune against it. The blood of the immune person is said to contain specific *agglutinin* for the typhoid bacillus. There is reason to believe that the clumping of the bacilli leads to their more effective removal from the blood and more rapid destruction in various tissues of the body. That is the reason why agglutinin is considered to be an antibody or immune body. Similarly, it is known that the blood of the immune person has an increased property of causing the precipitation of products of the typhoid bacillus. This property is ascribed to another antibody, the *precipitin*. Furthermore, the blood of the immune person may have powerful action in preparing the typhoid bacillus for ingestion by phagocytes. This property is called *opsonic* and is supposedly due to another antibody, the *opsonin*. In addition to the agglutinins, precipitins and opsonins, there are other antibodies that need not be discussed here. It is not certain whether these antibodies are distinct or whether they are really identical, the differences being due to what they act upon rather than to what they are and how they act. Suffice it to say that they provide an understanding of the nature of the acquired immunity against certain microbes. The example cited was the case in typhoid fever. The statements would be equally true if the name of that disease were replaced by the name of any one of a long list of infections. In each case, the antibodies are specific against the microbe (or its products) by which the body was aroused to produce them. That is why we speak of typhoid agglutinins, dysentery agglutinins and so forth. In the rôles played by antitoxins and by antibacterial antibodies, we have the modern understanding of acquired immunity.

Artificially Acquired Immunity. The immunity discussed above is called "naturally acquired" because it depends upon the fact that the individual contracts a disease in the natural course of events. One of the most beneficial discoveries ever made is due principally to Edward Jenner (1749-1823). He showed that when a human being has an infection with the germ of cowpox, which is an extremely mild disease in man, the body becomes immune against smallpox, which is an extremely dangerous disease. Jenner then showed that if an individual is given a mild, local cowpox infection (on the arm or leg), the body has acquired a general immunity against smallpox. This is the process of arousing *artificially acquired immunity*, so called because the infection that brings it about is produced artificially instead of naturally. It is now understood that the germs of cowpox and smallpox are probably the same, and differ only in the fact that life in the cow has made the cowpox germ less capable of producing a severe infection in man. The germ of cowpox is said to be less "virulent" for man than the germ of smallpox.

About seventy-five years after Jenner's discovery, Louis Pasteur (1822-1895) discovered the same principle. In addition, he actually invented methods of making pathogenic bacteria less virulent so that when they are introduced into an animal body they cause only a very mild infection but arouse immunity against highly virulent bacteria of the same kind.

It might now be asked: If acquired immunity can be aroused in the body following a mild as well as a virulent infection, can it also be aroused by dead bacteria or by the products of the living or dead bacteria? The demonstration that this can be done was first made by a great American scientist who is still living (1931), Doctor Theobald Smith. This discovery opened the way to the most important method of preventing disease: IMMUNITY MAY BE ACQUIRED WITHOUT DISEASE BY INTRODUCING INTO THE BODY THE PRODUCTS OF BACTERIA OR THE KILLED BACTERIA. In the case of diseases due to a toxin produced by the bacteria, artificially acquired immunity may be produced by injecting an extremely small quantity of the toxin. More often a mixture of toxin and antitoxin, called "t.-a.," is used. Thus the poisonous power of the toxin is neutralized and counteracted by the antitoxin. This treatment results in the appearance of antitoxin in the blood. For diseases caused by bacteria themselves, a suspension of dead bacteria, called a *vaccine*, is injected. This treatment results in the appearance of antibacterial antibodies in the blood.

The production of immunity by the injection of a toxin-antitoxin mixture or a vaccine, when properly carried out by a physician, is a safe, harmless and reliable way of producing immunity against the particular disease concerned.

Active and Passive Immunity. When an individual contracts a disease, recovers and becomes immune, he has manufactured substances upon which his immunity depends. This is an active immunity. The immunity following the injection of a toxin-antitoxin mixture or of a vaccine is similarly an active immunity. If the blood of an actively immunized person is injected into a non-immune individual, the latter is made immune. The latter did not manufacture his own immunity; he received it passively from the former. For this reason, his immunity is said to be a "passive" one.

The antitoxins or other antibodies which occur in the blood are found to be present in the blood serum—the fluid which separates after blood is shed and is permitted to clot. About fifty years ago, when antitoxins were first being discovered by Doctors von Behring and Kitasato in Germany, and Doctors Roux and Yersin in France, the following facts were proven by experiments on guinea pigs. (1) The animal which recovers from infection with diphtheria bacilli can later survive a still stronger infection. (2) The animal which is injected with small doses of diphtheria toxin, in a few weeks can survive the injection of doses of toxin which kill normal, untreated guinea pigs. (3) If a little blood or blood serum from such an immunized guinea pig is mixed with a large dose of toxin before the toxin is injected into a normal guinea pig, the animal will survive. (4) If a little of this blood or serum is injected into a normal animal it will survive the injection of large doses of toxin. These facts can be summarized by saying that the antitoxin produced actively in the body of one animal, when it is mixed with toxin or when it is injected into another animal, will protect a guinea pig, horse, rabbit or human being against the toxin of the diphtheria bacillus. It does not matter in what species of animal the antitoxin is made; the serum that contains it is effective. Hence, when a child has diphtheria or needs to be protected because it has been exposed to infection, the physician injects a suitable dose of diphtheria antitoxin. Because this must be continuously kept on hand in large quantities, antitoxin is made in horses by injecting them with small doses of toxin, taking small quantities of blood from them at various intervals, separating the serum from the clot, and carefully purifying the serum so that it contains a maximum of antitoxin and a minimum of everything else.

Serum containing antibacterial antibodies is also usually prepared in horses by injecting them with suitable vaccines and preparing the serum as described for antitoxin.

There is one fundamental, practical difference between active and passive immunity that must not be overlooked. In an actively immunized animal, whether by natural or artificial means, the body has made its own immunity and keeps it. The individual tends to remain immune for years or tens of years or an entire lifetime. In the passively immunized animal, the antitoxin or other antibodies were made in another animal. They are excreted fairly rapidly from the body into which they were injected. For example, the child that becomes actively immune against diphtheria because of an attack of the disease or from treatment with

toxin-antitoxin mixture usually remains immune for life; but the child that is made immune by an injection of horse serum containing diphtheria antitoxin usually loses his immunity in a few weeks or months and again becomes susceptible to the infection.

The facts described in these paragraphs have been illustrated principally by examples from diphtheria and typhoid fever. They apply in general to all diseases such as scarlet fever, tetanus, dysentery and meningitis, in which immunity depends upon antibodies in the blood. There are a few diseases in which immunity appears to depend chiefly upon the activity of the fixed tissue phagocytes (p. 987). In these cases, the passive transfer of immunity cannot yet be accomplished by any well established methods.

ANTISEPTICS AND DISINFECTANTS

If an object contains pathogenic (disease producing) microörganisms it is said to be *infected*. If by one means or another these microörganisms are destroyed, the object is said to be *disinfected*. It will appear shortly that there are many agencies that may be used to disinfect objects, but it will be plain that such agencies, known as *germicides* or *disinfectants*, are effective only under specified conditions. Let us suppose that the disinfectant being used for a particular purpose is heat. If an object is raised to a sufficiently high temperature, all the microbes, including the pathogenic ones, will be destroyed. At such a temperature heat is a disinfectant. Suppose we use a lower temperature. It may be too low to destroy all pathogens, but it may be high enough to keep them from growing or increasing in numbers. At such a temperature, heat is not a disinfectant, but is an antiseptic. At a still lower temperature, heat may have no restricting effects whatever. Similarly, a chemical substance may be destructive (disinfectant) when used in a suitably high strength or concentration, only inhibitive (*antiseptic*) in lower concentration, and without significant effect in still lower concentration.

Sunlight. Many kinds of microbes are destroyed by sunlight, provided it has not passed through glass. The reason for this is that it is the ultra-violet rays in sunlight that are chiefly effective, and these rays cannot pass through ordinary glass. Microörganisms in or upon anything that is not in the direct path of sunlight are not easily killed by it. Furthermore, many microbes are not very sensitive even to direct light. For these reasons, sunlight is not generally a reliable disinfectant. Its principal value in connection with disinfection is that people are likely to use soap and water or other more effective substances when sunlight reveals dust, dirt or filth.

Heat. Heat is in many ways the surest and cheapest disinfectant. For many purposes it is the best to use. It is important to remember that the speed of action of heat or any disinfectant usually depends on water or moisture. If the food or other substance that is to be disinfected is in water or is moist, boiling temperature (212° Fahrenheit) will kill practically all germs in a few minutes. If the substance is dry, a much higher temperature is required to sterilize or disinfect it. It is usually necessary to bake a dry object in a hot-air oven at a temperature of about 340° Fahrenheit for an hour or two hours to kill all germs. If the temperature is higher than 340° Fahrenheit, a shorter time will be effective. If an oven is available, but no thermometer with which to measure the temperature, place a piece of common wrapping or writing paper in the oven with the things that are to be sterilized. Increase the temperature until the paper begins to turn brown, and keep the temperature at that point for the required time. Paper is a safe index because it turns brown at a temperature of about 350° Fahrenheit. Such things as used surgical dressings, food from the tray of a person with infectious disease, nose wipes, old clothing or linens, should be burned in an open fire, stove or furnace. After handling materials in need of disinfection, the hands should be carefully cleansed with denatured alcohol or by a thorough scrubbing with liquid green soap or a similar skin disinfectant.

In general, it is safe to say that if it is intended to sterilize something, heat should be used unless there is a definite advantage or preference for another means. If heat can be utilized, boiling for ten to thirty minutes is the safest and cheapest procedure. But if it is desired to sterilize such things as clothing or bandages or other things that need to be kept dry, place them in a hot-air oven and use a high temperature (about 350° Fahrenheit) for about one or two hours.

Chemical Disinfectants. For most common purposes, chemicals (solids, liquids and gases) serve as the most useful disinfectants. Chemists are continually discovering and inventing new ones—some that are effective for one purpose, and others, for another. On many occasions it matters little which one of many common disinfectants is used. At other times it is important to choose the disinfectant with discrimination—one, for example, which will destroy microörganisms but not tissues or such things as clothing, furniture, books or bed linen. Some disinfectants are more effective than others in penetrating dirt; some act better than others in the presence or absence of water; and some are so much cheaper than others that cost will often determine the choice.

Scientists are always searching for the ideal disinfectant: a substance that would be deadly to germs and yet harmless and non-poisonous to man; something that could be made cheaply; would be active even though dirt or other things were present; would not change by being kept for long periods of time, and would act quickly. The ideal disinfectant has not yet been found, but there are substances which have some of the properties of the ideal. Such a drug as quinine is used in the treatment of malaria because, if taken in suitable doses, it is very deadly to the malaria germ and is harmless to the patient. There are other drugs that are injected into patients who have certain diseases because these substances have the marvelous properties of being deadly to the particular microbes that are to be destroyed and rather harmless to the human body. In the future there will probably come the invention and manufacture of such drugs to the point where they will work almost unbelievable wonders in the specific treatment of disease.

For the present it must be remembered that, if a substance is deadly to the protoplasm of microbes, it may also be deadly to the protoplasm of man. Therefore, unless the contrary is specifically known, it is always safer to assume that a disinfectant is a poison, especially if taken internally. All poisonous substances that are kept in the house should be carefully labeled and marked "POISON."

Among the thousands of chemical disinfectants used, under various trade names and in a variety of combinations, only a few may be specifically mentioned.

Alcohol. Wood (methyl) alcohol and grain (ethyl) alcohol are good disinfectants. They are specially useful for the skin or other external parts of the body. Wood alcohol is more dangerous than grain alcohol because the former is very poisonous to the nerves of the eyes. Denatured alcohol is just as good a disinfectant as pure alcohol. Denatured grain alcohol (in fifty or seventy-five per cent solution), specially prepared for external use, is a safe disinfectant. If kept around the house it should be labeled "POISON," because the substances used in denaturing it are poisonous if taken internally.

Common Salt. Common table salt is more of an antiseptic than a disinfectant. Any food to which it is added in large quantities will usually be preserved from spoiling because the salt interferes with the growth of bacteria, yeasts and molds.

Hydrogen Peroxide. Hydrogen peroxide, in the form in which it is commonly kept in the household, is useless because it decomposes rapidly. In the three per cent solution in which it is usually sold it is a mild antiseptic; but it is usually too weak to kill bacteria that may have gained entrance into a cut or wound. If kept in strong solution and tightly stoppered, it is one of the most powerful of the nonpoisonous disinfectants.

Copper Sulphate. Copper sulphate is not very valuable for household uses. It is a very important disinfectant in certain water supplies because it has very strong action against certain small plants, the algae, which give bad tastes and odors to drinking water.

Bichloride of Mercury or Corrosive Sublimate. Bichloride of mercury or mercuric chloride, also known as "corrosive sublimate," is one of the most powerful and most useful disinfectants known to man. It is so powerful that even when there is only one part of the substance in 1,000, 5,000 or 10,000 parts of water, it will kill all microbes. (One ounce dissolved in eight gallons of water is one part to 1,000 parts of water.) When used properly in sufficient concentration and permitted to act for at least ten to thirty minutes, it can be relied on to kill all microörganisms.

Bichloride of mercury can be purchased in tablets ready to add to water. The pure substance has no color, but a coloring substance, blue or red, is usually added to the tablets so that the solution will not be mistaken for pure water. The reason for this is that bichloride of mercury, if swallowed, is very poisonous to human beings. If it is kept about the house, it should always be in bottles labeled "POISON." It is safe to use externally. When used to disinfect excreta or other things, the solution should be allowed to act for an hour and should be thoroughly stirred up with the material to be disinfected.

Silver Nitrate. Silver nitrate is a very powerful disinfectant; it is nearly as powerful as bichloride of mercury. It is especially useful to prevent blindness in babies. A few drops of a one per cent solution should be placed in each eye of every baby directly after birth to prevent infections.

Argyrol and protargol are two among many chemicals that contain silver and are very good disinfectants. Argyrol is specially useful because it is not so injurious to tissues as silver nitrate. It can be used even in twenty-five per cent solution in disinfecting such delicate tissue as the eye. It is used in the throat, nose and other parts of the body to combat local infections.

Tincture of Iodine. Tincture of iodine is a solution of iodine in alcohol. It is very useful as a disinfectant because it has the germicidal power of alcohol and of iodine combined. As long as it is not taken internally it is a safe, as well as a reliable, disinfectant. It is probably the most useful disinfectant for household first aid. Although it is poisonous, its color and odor make it difficult to mistake for anything else. It can be applied safely to cuts, wounds, bruises or injuries for the purpose of killing microörganisms that may be introduced into the tissues.

Lime. Lime is one of the cheapest reliable disinfectants. It is useful in two forms: (1) Quicklime and slaked lime are strong disinfectants. Whitewash is slaked lime and water. It is specially useful on walls of barns, cellars, stables, and out-buildings. Lime is very valuable in the disinfection of excreta if thoroughly stirred up with the material that is to be disinfected. (2) Chlorinated lime or chloride of lime, also known as "calcium hypochlorite," is particularly powerful because it gives off the powerful disinfectant chlorine. Formerly it was used even in disinfecting drinking water. In modern days it is cheaper and more convenient to use compressed chlorine gas or "liquid chlorine" for the disinfection of large quantities of water, as in the case of a city water supply. For small water supplies, as for a village or farm, chlorinated lime is still very convenient and useful.

Coal Tar Disinfectants. There are a great many good disinfectants that are made from coal tar. Perhaps the best known of these is carbolic acid, or phenol. Cresol, tri-cresol and many other similar preparations are good disinfectants which are only moderately expensive. There are hundreds of similar disinfectants, sold under trade names, most of which are efficient, but expensive.

Soap. Soaps have been used for many thousands of years as cleansing agents. By cleansing things, soap helps to get rid of germs. Some soaps are disinfectants as well as cleansers. Soap is most effective when used with hot water.

Gas Disinfectants. There are some occasions when it is desirable to fumigate a room or house. Formaldehyde (formalin) is one of the most effective fumigants when properly used. Because it is a somewhat dangerous substance, it should be used only by an expert. Burning sulphur or exposing a room to chlorine or cyanide gas, although still used for disinfection, are much more useful for killing insects, bugs and rats than for killing microbes. In general, fumigation is no longer widely practiced because it is not usually efficient. Furthermore, we know now that most disease germs die quickly when they leave the body, and it is no longer considered so important to fumigate. It is far more important to avoid close contact with the sick or infected person and to disinfect the patient's excreta and the clothes, linens, dishes and other things which he has used than to attempt to disinfect the room in which he has been confined. Modern medical practice relies upon "concurrent" rather than "terminal" disinfection of the sickroom.

Carbolic Acid (Phenol) Coefficient. The standard test for the strength of a disinfectant is the so-called "carbolic acid or phenol coefficient." This consists in comparing the efficiency of a substance with that of a five per cent solution of carbolic acid, both acting under the same conditions on suspensions of typhoid bacilli. The "coefficient" is the number which expresses how many times weaker or stronger the solution of the substance tested can be, and yet be as effective as carbolic acid. A phenol coefficient of ten means that the substance was as effective as phenol when used in one-tenth as strong a solution; a coefficient of one-tenth means that the substance tested had to be in ten times as strong a solution in order to be as efficient as the phenol.

Although the phenol coefficient is one of the most useful indexes to the strength of a disinfectant, it is not altogether reliable because it does not predict with certainty what will happen in the presence of interfering substances like sputum, dirt or excreta.

COMMUNICABLE DISEASES AND THEIR PREVENTION

In the following paragraphs are presented the essential facts about the principal communicable diseases and the most important methods that are available for their control. It is plain, of course, that the diagnosis and treatment of the disease must be left to the physician. However, the intelligent citizen should know enough about these infections to know when to call the doctor and how important it is to follow his directions. The essential duty of every citizen, old or young, is to coöperate in the attempt to prevent the spread of disease from person to person.

It is difficult to arrange diseases in a logical way. Classification is made according to various characteristics: (1) the type of microbe that is responsible; (2) the parts of the body principally affected; (3) the type of body discharges by means of which the disease is commonly spread; (4) the methods of prevention or treatment, and so forth. For the purposes of this book, however, the diseases that are discussed are listed alphabetically. They are discussed largely after the plan and the form used by the Committee on Standard Regulations (U. S. Public Health Reports, Dec. 17, 1926), from whose report we have borrowed freely.

Anthrax. This is primarily a disease of herbivorous animals, especially cattle, hogs, sheep and goats, and one which may be spread to man. This disease is also known as "malignant pustule," because the infection in man commonly starts as a pustule or carbuncle on the skin of the face or neck. It is caused by a bacterium, *Bacillus anthracis*, which has gained entrance into an accidental scratch or wound. An infected individual is capable of transmitting the bacillus to other persons as long as he is actively sick or the wound discharges pus. The hair and hides of infected animals may carry the microbe or its spore for many months after the animal was slaughtered or after the hide was cured, unless it was carefully disinfected. The control of the disease requires its early diagnosis and the disinfection of discharges from the lesions and of all articles soiled by blood or pus. Furthermore, the prevention of anthrax demands that all infected animals should be placed under the care of a veterinary surgeon and, if they die or are killed, their carcasses should be burned. Healthy animals should be segregated from the infected ones, and no milk should be used from any animal that is suffering from anthrax. All persons employed in occupations requiring the handling of rawhides, hair or bristles should promptly see a physician if an abrasion of the skin occurs, or if a persisting boil or carbuncle appears.

Chickenpox. This is a mild disease which attacks a large percentage of children. Those who escape it in childhood may contract it in adult life. It occurs with an eruption on the body, face and scalp, and is usually accompanied by mild, general symptoms of illness. The infectious agent, which is still not known, is present in the eruptions and on the mucous membranes. The disease is usually spread from person to person by contact; or indirectly through articles that have been freshly soiled by discharges from the infected individual. The infected person may be able to infect others until the primary scabs have disappeared from the mucous membranes and skin. Chickenpox is not very dangerous in itself. When a case occurs which is thought to be chickenpox, particularly in persons over fifteen years of age or in persons of any age during an epidemic of smallpox, the patient should be carefully examined by a physician to eliminate the possibility of confusion with the more dangerous disease of smallpox. The child suffering with chickenpox should be kept away from others who have not had the disease. One attack of the disease usually confers upon the individual a permanent immunity. The disease is not known to occur in any of the lower animals.

Colds. The "common cold" ("acute coryza") is a catarrhal inflammation of the upper respiratory tract. It is not certain whether it is a simple disease or a group of diseases. Although there is good reason to believe that it is caused by microörganisms and is infectious and contagious, it is not yet certain whether a particular species or a variety of species of microbes is responsible. The disease is sometimes known by other names such as "acute rhinitis," "acute laryngitis," "acute pharyngitis," according to whether the inflammation occurs principally in the nose, larynx or pharynx. It is well known that such factors as fatigue, chilling, wet feet, wet clothing, drafts and irritants in the air sometimes appear to "bring on" colds. How these factors operate is not clear.

The "cold" is in itself not a dangerous disease, but it frequently leads to more serious

affections of the respiratory organs, particularly to pneumonia. For this reason it must be treated seriously.

The prevention of the spread of colds depends upon avoiding contact with the infected individual and with all objects which he has recently touched or which he has contaminated with discharges from the mouth or nose. The affected person should be extremely careful to avoid close contact with others, should stay away from crowds and from public places, should cover mouth and nose when sneezing or coughing and use soap and hot water or a disinfectant for hands and handkerchiefs.

Diphtheria. This is the most important and most deadly disease of childhood. Although enormous strides have been made in its prevention, it still is very common. It may be safely said that enough is known about diphtheria to control and wipe it out altogether. Its persistence in a community is due to the failure of people to utilize available scientific knowledge and facilities. The disease is caused by *Bacillus diphtheriae* which is present in the discharges from lesions in the nose, throat, eyes and other organs, and may be present in the nose and throat of a healthy person. It is well established that many persons who are themselves in apparently good health may be "carriers" of the microbe and may be spreading them to other persons who can contract the disease. Inasmuch as there is no convenient way of detecting all carriers, and no reliable method of freeing the carrier of the microbes after he has been detected, the sources of the infection cannot be entirely controlled. The principal symptoms of the disease are due to the toxin produced by the bacilli. In addition to contact from person to person, diphtheria bacilli may be spread in a community through infected milk or milk products.

The control of diphtheria depends upon the following:

(1) Early diagnosis of the disease by the doctor. If antitoxin is injected on the first day of the disease the patient is almost certain to get well; the longer the delay in injecting the antitoxin, the greater the danger. It is extremely important that the physician be called promptly when, because of general illness or sore throat, diphtheria is suspected.

(2) Isolation and quarantine of all persons until they have recovered and until suitable bacteriological tests show that they are free of virulent diphtheria bacilli.

(3) Making all susceptible persons who have been exposed to infection immune against the disease by injection of antitoxin. Whether or not an individual is susceptible is easily determined by the Schick test. This test consists in injecting a very small quantity of toxin into the skin. If the individual is immune, he has antitoxin in his blood, the injected toxin is neutralized and no reaction follows. He is then said to be "Schick negative." If the individual is not immune, he lacks antitoxin, and a slight reddening develops in the skin at the site of the injection. Such a person is said to be "Schick positive." The Schick test is so called after Doctor Bela Schick who first developed it into a practical method of discovering which persons have, and which ones lack, antitoxin in the blood.

(4) Disinfection of all articles which have been in contact with the patient, and all articles soiled by discharges from the patient.

(5) Pasteurization of the milk supply (see pp. 1009-10).

(6) The active immunization of all children in the community, is the most important procedure of all. This should be done preferably between the sixth or seventh month and the end of the first year of life. In any community in which this is not being done, active immunization, with or without the prior use of the Schick test, should be done for all school children and so far as possible with all children of pre-school ages. Active immunization, it will be recalled (p. 1000), consists in injecting under the skin a small quantity of toxin-antitoxin to stimulate the body to manufacture its own antitoxin.

From experience with hundreds of thousands of children it has been well established that practically all children can be made immune against diphtheria with from one to four injections of toxin-antitoxin. It is the duty and obligation of every parent to arrange to have a physician give this treatment to every child after the sixth to ninth month of life. If this were done, there would be no diphtheria in the family or community. There are now many cities in the United States with populations over 50,000 which have gone from one to three years without a single case of diphtheria. This gratifying condition exists because all children have been made immune, and all new babies were being made immune near the end of the first year of life as soon as they became susceptible by the gradual loss of the antitoxin which they had obtained from their mothers before birth. Diphtheria is an easily preventable disease and should not occur among intelligent people. It cannot occur in a child that has been made immune.

Dysentery. Dysentery is a diarrheal disease which usually occurs only in warm or tropical parts of the world. There are two important kinds of dysentery.

One variety of dysentery, "amebic," is caused by a protozoan organism belonging to the class of ameba; the particular parasite is *Endameba histolytica*. The source of the infection is commonly the bowel discharges of infected persons. The disease is transmitted by drinking water which has been contaminated with the sewage of infected persons, by eating infected foods and by hand-to-mouth transfer of infected material; from objects soiled with the discharges of an infected individual or of a carrier; and by flies from infected excreta to foods. The control of amebic dysentery depends upon the early diagnosis of the disease, including the recognition of the ameba in the stool, the disinfection of all bowel discharges, and by supervision of the water and food supplies to insure that they are free from contamination with excreta.

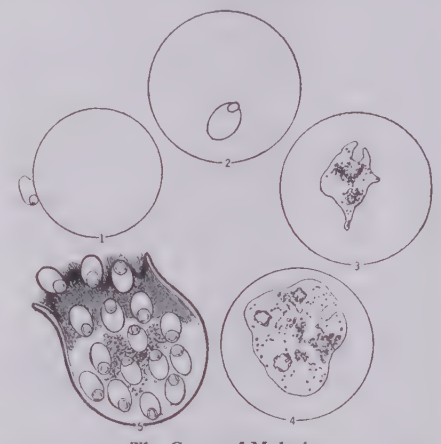
The other kind is "bacillary" dysentery, caused by *Bacillus dysenteriae*. This form of dysentery is spread in the same way as the amebic form. Its prevention depends upon the same procedures and, in addition, upon making individuals exposed to infection immune by means of a vaccine, and in very rigid observance of the rules to avoid contamination of food. No person who has bacillary dysentery, or who is a carrier of the bacillus, or who is in contact with a patient, should have any relations with milk production or food preparation. When dysentery is prevalent in a community, all water, milk and foods should be cooked, and all milk and foods should be protected against contamination by flies and human handling.

German Measles. This disease, also known as "rubella," is an acute, highly contagious disease of childhood, and is very much like measles and scarlet fever. The infectious agent is unknown but is probably present in the secretions of the mouth and perhaps in the nose. The disease is almost always mild. One attack usually confers immunity for life. Control depends entirely upon separating the patient from non-immune children, and upon excluding the patient from school and public places for about eight days after the onset of the disease.

Gonorrhea. This is an acute, infectious disease of the sex organs, and is usually spread by sexual contact. It is a very common disease in all parts of the world, recent figures indicating that in many civilized countries as many as from twenty to thirty persons in every thousand contract the disease each year. It may be spread by personal contact (other than sexual) with infected persons, and indirectly by contact with articles freshly soiled with the discharge of such persons. In the newborn baby of an infected mother, gonorrheal infection is likely to occur in the eyes. The disease is sometimes looked upon as of little consequence. This is not the correct point of view, because it is very frequently a serious and dangerous disease which may lead to bad affections of the joints, heart and other parts of the body.

The prevention and control of gonorrhea depends chiefly upon: (1) recognition of the disease; (2) isolation of infected persons and exclusion from sexual contact; (3) exclusion from school or contact with children of persons who have contracted gonorrheal infection of the eyes; (4) disinfection of discharges from lesions; (5) elimination of common towels and common toilet articles from public places; (6) exclusion of persons in the active stages of the disease from participating in the preparation of food; (7) education of the public in matters of sex hygiene, in understanding that continence is not dangerous to health, and that a case of gonorrhea or other venereal disease is commonly the consequence of association with persons who are sexually delinquent or promiscuous.

Hookworm Disease. This disease is due to the presence of certain parasitic worms in the intestines. It is a disease of warm countries and is widely prevalent in tropical and subtropical climates. In many countries (India, China, Malay States, northern and central Africa, Porto Rico, southern United States, Central America, South America, the West Indies, and other places), from sixty to a hundred per cent of the people are afflicted with chronic hookworm disease. There are two specific parasites, called *Ankylostoma duodenale* and *Uncinaria americana* (or *Necator americanus*). Hookworms are round worms (nematodes) and are classified in the family *Strongyloidea*. The adult



worm is about one-half to three-quarters of an inch long and about as thick as an ordinary hairpin. The disease is characterized chiefly by anemia, "laziness," weakness, lack of energy. It is easily understood that countries whose people are infected with hookworms, and are therefore weakened and anemic, cannot be very progressive.

The usual source of infection is the feces of infected persons. The infection usually occurs through the skin, though frequently by way of the mouth. To understand how to prevent and control hookworm disease it is essential to understand the peculiar life history of the parasite. The adult worms in the intestine gain their nourishment by biting into the intestinal wall and sucking blood. There may be hundreds or thousands in a single person, so that it is not surprising that the individual is anemic, weak and "lazy." There is also some evidence that the worms produce a toxin. The mature female worm produces eggs (ova) which are excreted in the stools of the infected individual. When the excreta are deposited on the ground, the eggs grow into larvae which hatch out in from twenty-four to seventy-two hours. After about five days they become encysted and are then capable of infecting man. The commonest form of infection occurs through the skin of the feet. Hookworm infection is a disease of poor people (who go about without shoes) living in warm climates, where proper facilities for sewage disposal are lacking. (The ova develop more rapidly where it is warm.) The larvae penetrate through the skin, between the toes or elsewhere on the feet, giving rise to a condition called "ground itch." After they have once gained entrance to the body, they pass by a roundabout path to the intestines. Six to eight weeks after the infection they are laying eggs, and the cycle is repeated. Infection may also occur by drinking water containing larvae, by eating contaminated food and by hand-to-mouth transfer of ova or larvae from contaminated objects. Contaminated soil is the principal source of infection.

As long as an individual is discharging ova he is infective. Soil may be infective for as long as from four to six months if it has not frozen over in the interim. The control of hookworm disease depends upon the following: (1) diagnosis of the disease by general symptoms and by finding the ova in the excreta; (2) proper disposal of sewage to prevent contamination of the soil, of water and foods; (3) suitable treatment of infected persons to free them of worms and ova; (4) education of the public concerning the nature of the disease and the dangers of soil pollution; (5) economic improvements or philanthropic action in the form of distribution of shoes in places where the poor and the ignorant can be persuaded to wear them.

Influenza. This is an acute infectious disease of the upper respiratory tract, usually occurring in epidemics in the cold season of the year.

"During epidemics efforts should be made to reduce opportunities for direct contact infection, as in crowded halls, stores and street cars. Kissing, the use of common towels, glasses, eating utensils or toilet articles should be avoided. The hands should be washed carefully before eating. In isolated towns and institutions infection has been delayed and sometimes avoided by strict exclusion of visitors from already infected communities. The closing of schools has not been effective in checking the spread of infection. The use of masks by nurses and other attendants has proved of value in preventing infection in hospitals. Scrupulous cleanliness of dishes and utensils used in preparing and serving food in public eating places should be required, including the subjection of all such articles to disinfection in hot soapsuds. In groups which can be brought under daily professional inspection, the isolation of early and suspicious cases of respiratory tract inflammation, particularly when accompanied with a rise in temperature, may be relied upon to delay the spread of the disease. To minimize the severity of the disease and to reduce

The Cause of Malaria

The life cycle of the protozoan parasite that causes malaria: 1. Malarial germ attacking a red blood corpuscle; 2. A malarial germ within corpuscle; 3. Malarial germ commencing to develop within corpuscle; 4. Further development of germ; 5. Fully developed germs bursting from corpuscle, each ready to attack another corpuscle.

mortality, patients should go to bed at the beginning of an attack and not return to work without the approval of their physician." (United States Public Health Service, Reprint No. 1129 from the Public Health Reports.)

The disease itself is almost never fatal, but it is extremely dangerous because it so commonly leads to pneumonia. In the last worldwide influenza epidemic in 1918-1919, it is estimated that from twenty-five to seventy-five per cent of all persons contracted the disease, and that tens of millions of persons died from pneumonia and other diseases which followed influenza.

Malaria. "It is difficult to draw comparisons in pathology, but I think, if a census were taken among the world's workers on mortality, the votes would be given to malaria as the greatest single destroyer of the human race. Cholera kills its thousands; plague, in bad years, its hundreds of thousands; yellow fever, hookworm disease, pneumonia, tuberculosis, are all terribly destructive, some only in the tropics, others in more temperate regions; but malaria is today, as it ever was, a disease to which the word pandemic is specially applicable. In this country and in Europe, its ravages have lessened enormously during the past century, but in the tropics it is everywhere and always present, the greatest single foe of the white man, and at times and places it assumes the proportions of a terrible epidemic. In one district of India alone, during the last four months of 1908, one quarter of the total population suffered from the disease and there were 400,000 deaths—practically all from malaria. Today, the control of this terrible scourge is in our hands..." (Osler, Sir William: *The Evolution of Modern Medicine*).

Malaria is due to three species of a protozoan microbe, *Plasmodium vivax*, *P. malariae* and *P. falciparum*. It is spread by the bite of an *Anopheles* mosquito. The mosquito becomes infected by biting (sucking blood from) an infected individual whose blood contains the parasites. These develop in the body of the mosquito for from ten to fourteen days. After that period, numerous mature parasites are present in the salivary glands of the insect, and may be injected into the person whom the mosquito bites. The individual who is actually sick with malaria and is having repeated chills and fevers is the most important source of infection. Many persons may appear to be well or cured and yet may harbor the parasites in their bodies for many years. The disease is communicable as long as the parasites are present in the blood.

This disease cannot be spread by the common *Culex* mosquitoes. Malaria is transmitted only by mosquitoes and usually occurs in warm and tropical climates where there is moisture, marshes and swamps, and where mosquitoes breed in large numbers and for many months of the year or all the year round. There can be no spread of malaria without mosquitoes.

The control of malaria is a problem of education, of medical practice, and, in part, a financial and economic problem for the whole population. The attack on the disease revolves around the control of the sources of infection (infected persons), (1) by making it difficult or impossible for mosquitoes to reach those who harbor the parasites and thus becoming infected; (2) by keeping houses screened so that normal persons are not easily reached by infected mosquitoes; (3) by the destruction of mosquitoes everywhere, and by eliminating all swampy places and large or small collections of water where mosquitoes may breed, and (4) by the use of quinine (which is a specific drug against the malaria parasite) to kill the parasite in sick persons, and the use of quinine to prevent infection in healthy individuals who are exposed to mosquitoes in communities where malaria prevails, is important in the combat with this disease.

It is not always possible to find all the infected individuals in a population, particularly in a community in which a very large proportion of the total are infected; it is often very difficult to persuade all persons to take quinine regularly to cure or prevent malaria; and it is often a matter of enormous cost and engineering difficulty to eliminate all mosquito breeding grounds. All of these methods must be used in combination. In some places one method is more effective, in other places, another.

Measles. This is an acute, highly contagious disease which occurs most commonly in the cold months of the year, but which

may occur in all seasons. It usually starts with catarrhal inflammation, fever and a rash which is followed by an eruption. If no complications occur it is usually a very mild disease. Pneumonia is the most serious complication that frequently follows measles. It is primarily a disease of childhood, but may attack adults of any age who have not had the disease before. Exposure of susceptible persons by contact with one who has measles almost invariably leads to infection. One attack usually confers immunity for life.

The specific infectious agent that causes measles is not yet certainly known. It is well established by infection experiments that the agent is present in the secretions from the eyes, nose and respiratory tract. The patient is most infective before the eruption has appeared. It is usually considered that the patient is infective from four days before, to five days after, the appearance of the rash.

The control of measles depends upon the following: (1) early recognition of the disease; (2) isolation of the patient during the time in which he is infective; (3) protection of persons who have been exposed to infection by an injection of "convalescent" serum. After an individual becomes infected, usually ten days elapse before the onset of symptoms. If the blood (or serum) from some one who is recovering from measles or of a healthy adult who has had the disease is injected within five days after infection, the disease may be prevented. The serum from a convalescent or an immune adult appears to contain protective antibodies; (4) exclusion from school and other public places of all susceptible persons (children or teachers) who have been exposed to infection, for fourteen days from the last exposure; (5) disinfection of all articles soiled with discharges from the nose and throat.

Mumps. This is an acute, infectious and contagious disease which is especially characterized by the fact that those salivary glands located just in front of, and below, the ears (the parotid glands) become swollen and enlarged. Other salivary glands and the genito-urinary and other organs may also be affected. Mumps occurs most commonly between the ages of five and fifteen years, but is not uncommon among young adults under thirty or thirty-five. It usually prevails in the cold months of the year.

The infectious agent of mumps is unknown. The secretions of the mouth and possibly of the nose are infective. The disease is spread from person to person by direct contact, or by articles freshly soiled with saliva, mucus or other discharges from the throat or nose of the infected person. The chief methods of preventing the spread of the disease are: (1) early recognition of the disease, particularly by the fever and the swelling or pain in the region of the affected glands; (2) separation of the patient from all children who have not already had the disease and exclusion of the patient from school and public places until the glands have healed; (3) disinfection of all articles soiled with the discharges from the nose and throat of the patient.

Meningitis. This is a general name for an inflammation of the meninges, the membranes which surround the brain and spinal cord. Many kinds of bacteria may cause meningitis, and all such infections are serious. They are not generally communicable because the microbes that have invaded the central nervous system do not easily escape from it to infect other hosts. There is one kind of meningitis which, though it is not a common disease, does occasionally break out in epidemics. This is meningitis caused by a coccus called "meningococcus" or *Micrococcus meningitidis*.

Meningococcus meningitis is also known as "cerebro-spinal fever." It is primarily a disease of children and soldiers, the latter being apparently affected in epidemics because overcrowding permits easy spread of the infection. Healthy carriers of the microbes of this disease are probably common and widespread. The infection is transferred from person to person principally through the discharges from the mouth and nose of infected persons. More or less direct contact and hand to hand or droplet infection appear to be essential; hence the significance of overcrowding. Control and prevention of the disease depend upon: (1) early diagnosis of the disease; (2) isolation of infected individuals for at least fourteen days; (3) disinfection of discharges from the mouth and nose; (4) discovery of carriers by bacteriological examination and, if possible, their isolation; (5) education of the public in the importance of personal cleanliness and the avoidance of contact and droplet infection; (6) prevention of overcrowding in private and public places.

Pneumonia. The term pneumonia is applied to various diseases which result from a number of causes. The common characteristic is that each is an inflammation of the lung. Various pathogenic bacteria, many of them commonly found in the nose, throat or mouth may cause the inflammation when the conditions are suitable. Just what these conditions are is not clearly known at this time (1931). If the disease involves whole lobes of the lung it is called "lobar" pneumonia; if it is lobular in distribution it is called "lobular" or "broncho-pneumonia." The pneumococcus (*Diplococcus pneumoniae*) is the commonest cause of all pneumonias.

Although accurate figures cannot yet be obtained, it is quite certain that pneumonia is one of the leading causes of death and should perhaps stand at the head as "the captain of the hosts of death." In recent years at least ten per cent of all deaths in the United States have been due to pneumonia, and the disease is approximately of equal importance in all countries of the world and in all climates. It is more prevalent in the cold than in the warm seasons of the year. It is well known that colds, catarrhs, chilling, exposure, fatigue and many mild diseases (influenza, measles, sore throat and so forth) predispose to pneumonia. Diet also appears to play an important rôle as is evidenced by the fact that persons suffering from scurvy or rickets are prone to attacks of pneumonia. All ages of life are susceptible, especially the young and the old.

It is a matter of strong controversy (1930) among students of pneumonia whether or not it is a contagious disease. There is no doubt about its infectious nature and about the identity of the microbes that are commonly responsible. There is also no doubt that close and intimate contact with infected individuals frequently results in the transmission of infection. There are, however, many who doubt that most cases of pneumonia are contracted by contagion from an actual case of the disease. They believe that the pneumococcus and other microbes which are potentially capable of causing pneumonia frequently inhabit the nose or throat of normal, healthy persons and cause disease when the resistance of the tissues is lowered by some predisposing cause.

It may be said that the control of pneumonia depends upon avoiding contact with persons suffering with an acute attack of the disease, and with articles freshly soiled with discharges from the nose and throat of a patient. It is also commonly recommended that people should avoid congestion in public places in the cold seasons of the year. Furthermore, it is of the highest importance to avoid fatigue, chilling and exposure, not to neglect colds and catarrhs, and by proper regard to diet, exercise, fresh air and temperance in the use of alcoholic beverages to maintain the body's resistance at the highest level.

Poliomyelitis (Infant Paralysis). This is an acute, infectious disease which occurs most commonly in children and which may result in extensive paralysis. The disease ordinarily begins abruptly with fever, nausea, vomiting, pain and perhaps stiffness of the neck. These may be followed by paralysis and death. The disease may occur in the form of occasional and isolated cases or in a sharp epidemic. It is a warm weather disease and occurs in all countries. Its prevalence usually increases during the warm months of the year and then declines with the coming of cold weather.

The causative organism of the disease is not certainly known. There is reason to believe that the infection is probably spread through the agency of healthy carriers and through the nose and throat discharges of infected persons or objects contaminated by them. Some investigators are of the opinion that bowel discharges or objects contaminated with their excreta may also contain the infectious agent in a virulent form. There is little doubt that persons in the active stages of the disease have, at times, contaminated milk supplies and that consumption of the milk has led to epidemics of infant paralysis.

The control of the disease is extremely difficult because there may be many healthy carriers in a community and because infected persons may be capable of spreading the infection for several days before the symptoms of disease have appeared in them. Nevertheless, there is reason to believe that in a measure the spread of the disease may be controlled by: (1) early recognition of the disease; (2) isolation of all recognized cases for three weeks from the beginning of fever; (3) quarantine for two weeks of children who have been exposed to infection and of adults of the household who may have contacts with children or who are food-handlers; (4) disinfection of discharges from the nose, throat and bowel of all patients; (5) during an epidemic, isolation of all children who have fever, until the diagnosis is made.

Enormous advances have been made in

the treatment of infant paralysis to prevent the development of permanent paralysis of arms, legs or other parts of the body, and to treat the paralyzed child by skillful "physiotherapy" to recover the use of parts that have been affected.

Rabies (Hydrophobia). There are few diseases that are more generally feared than rabies, and justly, because no human being who contracts it ordinarily ever recovers. Yet it is a disease against which a community can protect itself if it will only take the necessary steps. Rabies is a wound infection. It is due to an unknown virus which causes disease in lower animals as well as in man. All mammals are susceptible; dogs, wolves, jackals and foxes are most commonly infected. Rabies exists in all parts of the world, except in countries where rigid enforcement is practiced to control and exclude it. To understand the methods of control it is essential to know that the microbes of this disease attack the central nervous system and that they may be present in high concentration in the saliva of the affected animal. The microbe probably cannot penetrate the unbroken skin or uninjured mucous membranes. Hence, contact and ingestion are harmless. The infectious agent is capable of setting up disease when it gains entrance to the tissues as through a bite, scratch or abrasion.

Not every animal that is angry or "mad" is rabid; nor does the bite of every rabid animal necessarily lead to rabies. It is necessary, however, to consider the possibility of rabies in every case of bite by a dog or other animal that may be "mad."

The control and prevention of rabies depends upon a variety of procedures:

(1) Treatment of the wound. Every bite, scratch or abrasion caused by a dog or other animal that acts "mad," or "queer," or gives any other signs of being rabid should be treated promptly (preferably by a physician) with strong nitric acid. Disinfectants or germicides like carbolic acid, silver nitrate, alcohol, bichloride of mercury and so forth, which may be used for other purposes can not be relied upon to kill the virus of rabies. It is important that the treatment of the local wound be thorough and be done as promptly as possible.

(2) Kill the "mad" animal, if possible without injuring or destroying the head, because the diagnosis of the disease in the dog depends upon examination of the brain. If the animal is not certainly "mad," it should be tied up where it cannot bite humans or other animals and be kept under observation by a physician or veterinarian.

(3) Prevention of disease in the person who has been bitten by vaccination. It is one of the most fortunate things about rabies that the disease ordinarily has a long incubation period. In man there is usually a lapse of thirty days to several months after infection before the symptoms appear. This period may be shorter if the bites were very severe or were on the face, head or near large nerves. Commonly the incubation period is sufficiently long so that it is possible to keep under observation the animal that has done the biting to determine whether or not it will develop the disease, if it was not certainly "mad" at the time of the biting. Furthermore, the length of the incubation period makes it possible actively to immunize the patient before the disease develops. One of the greatest inventions of Louis Pasteur was the method of vaccinating human beings against this terrible disease. Hence, the vaccination is called the "Pasteur treatment." It consists in injecting into the patient a carefully prepared vaccine to stimulate immunity against the microbes that may have been introduced by the bite of a rabid animal. Persons properly given the Pasteur treatment practically never develop rabies. If they are bitten again, months later, the treatment should be repeated.

(4) Muzzling of all dogs on public streets or in public places.

(5) Detention and examination of all dogs suspected of having rabies or of being "mad."

(6) Immunization of all dogs each year in communities where rabies occur.

(7) Effective quarantine of all dogs coming into a community or the entire country, to ascertain whether or not they may be rabid.

That the recommendation of these regulations is sound is evidenced by the fact that such a country as England, which actually practices most of them, is nearly entirely free of rabies.

Scarlet Fever. This is an acute, infectious disease caused by bacteria (*Streptococcus scarlatinae*). It usually begins with sore throat, nausea, vomiting, fever and headache. A rash on the skin and roof of the mouth usually develops a day or two later, and this is followed by "peeling." Although the disease may occur in persons of any age, it is uncommon in children in the first year of life and occurs most commonly between the second and the twelfth years. The disease is most deadly to children in the second, third and fourth years of life. Hence, it is especially important to guard the very young against this infection.

Scarlet fever may be spread by healthy carriers of the streptococci or by diseased persons. The common sources of infection are discharges from the nose, throat, ears, abscesses—or from articles contaminated with the discharges — from scarlet fever patients. Transmission of the infecting organisms is usually associated with more or less direct, personal contact; but it may be accomplished indirectly, as through contaminated objects or milk or milk products. Epidemics of the disease have been definitely traced to infected milk. The affected person is usually infective for two to three weeks after the onset of the disease and until abnormal discharges have ceased and open sores and wounds have healed.

The control of scarlet fever depends upon: (1) early recognition of the disease; (2) isolation of the patient in the home or in a hospital until the end of the infective period; (3) testing for immunity to the disease of such persons as have been exposed to infection. The "Dick test" which is used for this purpose is similar to the "Schick test" for immunity against diphtheria (see page 1003). Those who give a positive Dick test should be actively immunized by the physician with a suitable preparation of scarlet fever toxin; (4) exclusion from school of children, teachers and others who have been exposed to infection, and of food-handlers from their work until seven days have elapsed since the last exposure to a recognized case; (5) disinfection of all articles which have been in contact with a patient or soiled by his discharges; (6) daily examination by a physician, when possible, of all persons who have been exposed to infection; (7) pasteurization of the milk supply.

Smallpox. This is a widespread disease which starts with general symptoms of infection—chills, fever, nausea, vomiting and so forth—and is definitely recognized by the more or less characteristic eruption which develops about the third, fourth or fifth day. It was once one of the most prevalent diseases in the world, killing or pockmarking old and young, sometimes in great epidemic waves that would sweep through a people, sometimes as it made its way more slowly but certainly through a population. Professor Rosenau of Harvard University says of it (*Preventive Medicine and Hygiene*, [1927], p. 27):

> It is very difficult for us now to realize that smallpox was once much more common than measles and much more fatal. Many of those who recovered were disfigured for life, left blind, or with some other serious consequence of the disease. For centuries smallpox was one of the greatest scourges. It depopulated cities and exterminated nations. In Europe alone, where its ravages were comparatively slight, it killed hundreds of thousands yearly. In the eighteenth century, of which we have the best records, almost everybody had it before he grew up. Parents often exposed their children to the disease in order to be through with it, just as they now sometimes do with the minor contagious diseases. In China a mother does not number among her children those who have not yet had smallpox, because she well knows how uncertain will be their stay in the family.
>
> The distinguished mathematician, Bernouilli, estimated that 15,000,000 people died of smallpox in 25 years in the eighteenth century. It has been estimated that 60,000,000 people died of smallpox during that century. Haygarth gives an account of a smallpox epidemic in Chester, England, population 14,713. At the termination of the epidemic there were but 1,060 persons, or 7 per cent of the population, who had never had smallpox. Many similar instances are cited in the literature. The French physician, De la Condamine (1754), said that 'every tenth death was due to smallpox and that one-fourth of mankind was either killed by it or crippled or disfigured for life.' Sarcone (1758) estimated the number of persons in Italy who suffered from smallpox as 90 per cent of the population.
>
> Smallpox was introduced into the Western Hemisphere by the Spaniards about fifteen years after the discovery of America. In Mexico within a short period 3,500,000 persons are said to have died of the disease (Chapman). Catlin (1841) states that of 12,000,000 American Indians 6,000,000 fell victims to smallpox. In Iceland in 1707, 18,000 perished out of a population of 50,000; that is, smallpox killed 36 per cent of the total population in one year.
>
> A good example is that of Boston in 1752, population at that time 15,684. Of this number 5,998 had previously had smallpox. During the epidemic 5,545 persons contracted the disease in the

usual manner, and 2,124 took it by inoculation. One thousand eight hundred and forty-three persons escaped from the town to avoid infection. There were, therefore, left in the city but 174 persons who had never had smallpox.

Although smallpox is no longer such a terrible scourge, it is still widely prevalent. In 1923 there were reported about 50,000 cases in Europe and about 30,000 cases in the United States. There is no doubt that these are only fractions of the numbers that actually occurred. Being intensely contagious, smallpox is not controlled by sanitation. Active immunization by vaccination is the only reliable, preventive measure. (The discovery of vaccination by Jenner is described on page 1000).

The microbe which causes smallpox is unknown at this time (1931). It is known to be present in the lesions of the mucous membranes and skin of infected persons. It is usually transferred from person to person by contact, but transfer may be accomplished through objects soiled with discharges from lesions or with feces or urine of the patient.

The control of smallpox depends upon: (1) accurate diagnosis of the disease; (2) hospital isolation of the patient in screened wards, free from vermin, until the disappearance of all scabs and crusts on the skin and membranes of the patient; (3) prompt vaccination of all persons who have been exposed to infection; (4) disinfection of all discharges from the patient. No article should leave the surroundings of the patient until it has been thoroughly boiled or subjected to equally effective treatment; (5) vaccination of all persons in infancy, revaccination of children on entering school (fifth to seventh year) and revaccination of everybody, old and young, when the disease appears in a severe form in a community. The reasons for these recommendations are that the immunity against smallpox, which follows an attack of the disease or vaccination, is neither absolute nor is its persistence certain. It is usually reliable that persons who have been successfully vaccinated within three to seven years are probably immune; but complete reliance should never be placed upon a former vaccination in the face of exposure to infection or existence of the disease in the community.

Syphilis. This is the most dangerous and most deadly of the diseases that are commonly spread by sexual contacts. It affects from six to ten per cent of all persons; it occurs among old and young and in all classes of society. It is the principal cause of insanity, childlessness, abortions and miscarriages. It is caused by a spirillum-like microbe, called *Spirocheta pallida* (or *Treponema pallidum*). The sources of infection are discharges from the lesions of the skin and mucous membranes, and the blood of infected persons, and articles freshly soiled with such discharges or blood in which the spirochetes are present. The spread of the disease occurs most commonly by sexual contact, but it may be occasioned by kissing, by more casual contact or indirectly through infected objects.

It must be emphasized that syphilis is an extremely dangerous disease, but it is both preventable and curable. Control of the disease depends upon:

(1) Early recognition and diagnosis of the disease by clinical symptoms, examination of the discharges and of the blood. The effectiveness of treatment depends upon how early and also for how long it is instituted. It is therefore very important that all persons who have been exposed to infection should promptly seek the advice of a reputable physician. It is worse than foolish to delay or avoid receiving sound professional attention because a false sense of shame has been permitted to surround the very names of the venereal diseases. Early preventive or curative treatment may make the difference between a lifetime of healthy living or one of broken health, disease and insanity,

(2) Exclusion of infected persons from sexual contacts and from preparation of foods during the early active stages of disease, and intelligent avoidance of kissing and other close contacts.

(3) Avoidance of common towels, drinking cups, toilet articles and eating utensils.

(4) Proper personal prophylaxis, advised by a reputable physician, to those who expose themselves to infection, especially in illicit sexual intercourse.

(5) Education of all persons to understand that sexual continence in both sexes and of all ages is compatible with health and normal development.

Tetanus. This is a "wound infection" disease caused by *Bacillus tetani*. This microbe is apparently harmless when swallowed, and becomes dangerous only when it gains entrance to injured tissue. (The probable reason for this is that *B. tetani* is an anaërobic microbe, requiring the absence of oxygen in order to be able to grow and produce its poison.) It is frequently present in animal manure, soil and in street dust. Infection ordinarily occurs through wound infection with dirt which contains the bacillus. The patient affected with the disease is not ordinarily infectious to others. Prevention of tetanus depends upon: (1) removal of all foreign matter as early as possible from all wounds; (2) thorough disinfection of wounds; (3) use of tetanus antitoxin in all persons who have been seriously wounded or injured in regions where tetanus bacilli are known to occur in the soil and in all cases where wounds are ragged or penetrating. Tetanus was an unfortunately common cause of death among wounded soldiers in the early days of the World War. Then the practice was instituted in all the armies of giving every seriously wounded soldier a suitable dose of tetanus antitoxin as a preventive measure. Thus the disease was brought under control.

Other than occasional cases which occur the year round, tetanus is most prevalent in the United States directly after the Fourth of July; at this time many cases occur, following injuries due to celebration accidents. Tetanus is sometimes the terrible price paid by those who do not observe the "safe and sane Fourth."

Tuberculosis. There are many kinds of disease which are called "tuberculosis" and are caused by the *Bacillus tuberculosis*. The parasite has for years been one of the deadliest enemies of man. Lung infection is the commonest form of disease which it produces. This is "pulmonary tuberculosis" or "consumption," justly called the "Great White Plague." Until very recently the disease was responsible for from ten to twenty per cent of all deaths. Its control has only recently been made effective and there has already been a remarkable decline in its occurrence. Man's conquest over tuberculosis—as we see it occurring today—marks one of the greatest triumphs of hygiene and preventive medicine. There have been many serums and vaccines for tuberculosis advertised at one time or other. None is yet established. A new type of vaccine, devised by Dr. Calmette of Paris, is now (1931) in the experimental stage and holds some promise for the future.

The control of tuberculosis is extremely difficult because the microbe is widespread. Thus, in civilized communities nearly everyone becomes infected at some time or other in the first ten, fifteen or twenty years of life. Ordinarily the infection is conquered by the infected tissues and the individual is totally unaware of the battle that was waged between the microbe and the body defenses. Avoidance of repeated or massive infection is half the problem. The other half is concerned with keeping the body in good condition so that it is prepared to defend itself against microbic invasion.

The bacillus of tuberculosis may attack almost any part of the body, giving rise to lesions of the skin, glands, bones, intestines, kidneys and other organs.

Pulmonary Tuberculosis (*Consumption*). This is caused by the tubercle bacillus of the so-called "human" variety. It is present in the discharges of any open tuberculous lesions, the most important being the sputum. Infection is usually spread by direct or indirect contact by coughing, sneezing, or other droplet infection, kissing, common use of unsterilized food utensils, pipes, toys, drinking cups and other articles, and possibly by contaminated flies and dust. The danger of infection exists as long as the infected person is discharging the microbes.

The methods of control are: (1) recognition of the disease through examination by a physician using X-ray, skin tests and bacteriological examinations when necessary; (2) education of the affected person in how to avoid spreading infection; (3) careful disinfection of sputum or articles soiled with it (handkerchiefs, cloths, papers, eating utensils and so forth; (4) education of the public in the hygiene of the body to avoid and control infection; (5) provision of dispensaries and other facilities for the recognition of early cases and of facilities for their care, open-air schools for pre-tuberculous children; (6) ventilation and elimination of dust in factories and workshops and in places of public assembly; (7) separation of babies from tuberculous mothers at birth.

Other Forms of Tuberculosis (*Nonpulmonary*). The human or the bovine variety of the tubercle bacillus may cause affections of the skin, glands, bones and internal organs. The sources of infection are discharges from the mouth, nose, bowels, genito-urinary tract of infected humans; articles freshly soiled with such discharges; milk from tuberculous cattle. Infection may be transmitted by direct contact with infected persons, by contact with objects contaminated with their discharges, and by eating or drinking contaminated meat, milk or

other foods. Control of these infections revolves around: (1) early recognition of the disease; (2) disinfection of discharges and articles soiled with them; (3) pasteurization of all milk and inspection of meats; (4) elimination of tuberculous cattle from milch herds; (5) prohibiting all persons who have open tuberculous lesions from handling foods that are consumed raw.

Typhoid Fever. There is a group of infections of the intestinal tract caused by bacteria. Of these typhoid fever is the best example. This particular disease is caused by *Bacillus typhosus*. There are a number of bacterial species or varieties which are different but closely related, and which are capable of causing infections which are clinically similar to or identical with typhoid fever. The paratyphoid bacilli cause paratyphoid fever; others cause milder or more severe diarrheal infections. In all of these diseases there is fever, malaise, headache, acute gastro-intestinal upset with mucous or bloody diarrhea, complications in the liver or gall bladder function and so forth. In each of the diseases in this group the sources of the infection are the bowel discharges and urine of infected individuals or of healthy carriers of the microbes. The microörganisms are ordinarily spread by direct contact or indirectly through contaminated water, milk and shellfish. Contaminated flies have been common means of transmission in epidemics.

The control of typhoid fever and related diseases depends upon: (1) recognition of the disease from the clinical symptoms and confirmation by the agglutination test (see p. 1000) and by bacteriological examination of blood, bowel discharges or urine; (2) isolation of the patient in a fly-proof room, preferably under hospital conditions; (3) immunization by vaccination of all persons, so far as is practicable, in communities where the disease is prevalent, and especially of all susceptible persons in the family or household of the patient who have been or may be exposed during the course of the disease; (4) adequate protection and purification of public and private water supplies (see p. 1009); (5) pasteurization of public milk supplies; (6) supervision of other food supplies and of food handlers; (7) prevention of fly breeding; (8) sanitary disposal of human excreta.

So recently as two or three decades ago, epidemics of typhoid fever were common—one of the regular prices man paid for the privilege of living in cities. The disease was significantly reduced as soon as people in urban communities learned how to dispose of their sewage and keep it out of their water supplies, and how to disinfect the water they drank. When pasteurization of milk became more general, the incidence of typhoid fell still further. Now, as communities are learning how to discover carriers, eliminate them from food-handling occupations and educate them in hygienic living, typhoid fever is tending to become a rare disease. Occasionally one or the other of these defenses breaks down and an epidemic sweeps through the community. Typhoid fever is controllable; but eternal vigilance is the price.

Whooping Cough. This disease, also called "pertussis," is acute and contagious, and is caused by a small bacillus (*B. pertussis*). In its first stage it usually appears as a mild catarrhal infection of the upper respiratory tract. In the second stage the principal sign is the frequent coughing spells which usually end in a characteristic inspiratory "whoop." The disease is unlike most respiratory infections in that in the United States it is most common in spring and summer rather than in the winter months. It is principally an affection of early childhood, about one-fifth of all cases occurring in babies in the first year of life and another fifth in the second year. It is relatively uncommon in persons past the fifteenth year of life.

It is not generally known that whooping cough is one of the most dangerous of the common infectious diseases, not because it is itself mortal but because it may lead to pneumonia or other serious complications. Nearly every one suffers an attack of the disease at some time or other. The old-fashioned doctrine that children should be permitted to have it and be over with it, and

How Infection Travels
A reminder of the ways in which the microbes of disease may be spread.

"the sooner, the better," is dangerous, because the disease is far more deadly to young than to older children. One attack of the disease usually confers a lasting immunity, so that a second attack is rare.

The pertussis bacilli are usually present in very large numbers in the discharges from the lungs. These provide the common means of spread of the disease. It is known that cats and dogs are susceptible to pertussis, and it is thought by some that these animals may occasionally become infected and serve to spread the bacilli. The usual mode of transmission is contact with an infected person or with articles freshly soiled with discharges from a patient. The disease is especially communicable in the first seven to fourteen days when only the catarrhal signs usually exist, before the coughing and whooping spells have begun. After the whoop has appeared the patient may still be infective for three or more weeks.

The control of whooping cough depends upon: (1) recognition of the disease; (2) separation of the patient from susceptible children and exclusion of the patient from all public places for a period of from one week after exposure to infection until three weeks after the appearance of the whoop; (3) disinfection (by boiling) of all articles soiled by nose or throat discharges of the infected child.

Summary

This brief discussion of the principal communicable diseases of man may be summarized in a few phrases that are widely used by the sanitarian:

(1) These diseases are caused by the activities or poisons of microbes—bacteria, protozoa and so forth.

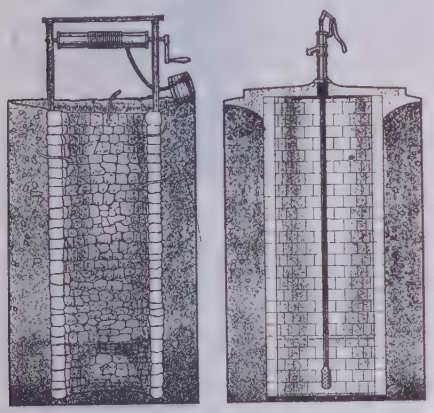
(2) Humans—not lower animals or the environment—are most commonly the reservoirs of infection, principally because most disease germs die out quite rapidly after they leave the body.

(3) The transmission of disease is most commonly accomplished by more or less direct transfer of the infecting agent from person to person (contact); less often through the intermediate infection of foods and fomites (inanimate objects in the immediate surroundings of man); and in occasional diseases (malaria, plague, yellow fever and others) through the intermediate agency of insects.

The phrase, "Fingers, Foods, Fomites and Flies" is often used to summarize it all and to remind people of the principles in the control of communicable disease.

CANCER

This is a diseased state of a tissue or organ due to the fact that the cells are undergoing excessive growth and multiplication. The cancerous tissues may remain localized and more or less harmless or may crowd upon and destroy normal tissues where it is growing. Small portions of it may be carried in the blood or lymph to other parts of the body and set up new growths in remote places. Cancer of the rapidly growing and spreading kind is extremely fatal. Enormous advances have been made in the diagnosis of cancer and in its treatment by surgical operation and by X-rays, radium and other means. Treatment is ordinarily most successful when applied in the early stages of disease. It is therefore of tremendous importance not to delay but to seek the diagnosis of a physician as soon as a suspicious lump or nodule appears in or upon the body. This applies especially to persons who have passed their fortieth birthday, because cancer is commonly a disease of the adult and late adult years of life.



The cause of cancer is not known at this time (1931). There is no substantial evidence that it is an infectious disease and no evidence that it is communicable.

COMMUNITY HYGIENE AND SANITATION

In the beginning of the nineteenth century, the invention of machines and the application of power started the Industrial Revolution. One of the necessities of the factory system that soon came into existence was the congregation of large numbers of persons in the vicinity of the place of work. Cities of the modern type grew where before there had been only villages and small towns. Urban life began to replace rural life for an increasing fraction of the population. With urbanization came problems of community hygiene and sanitation which had to be solved in order to avoid epidemics of contagious disease, water famines, unspeakable nuisances created by accumulation of sewage and wastes from large numbers of people herded into a small area. For most of these problems there are now adequate solutions.

Water Supply. Chief among the articles of food whose sanitary qualities must be guarded is water. This is particularly true because the conditions under which it is available in nature render its contamination and even infection relatively frequent. Because water is generally consumed raw, its pollution is unusually dangerous.

Protecting the Well. On the farm and in small communities, where water for drinking, cooking, washing and other purposes is usually drawn from a well, especial care must be taken. The well is usually in proximity to the house. Precautions must therefore be observed in locating and constructing the well so that pollution will not readily be flushed or drained into it. The most dangerous types of pollution are the intestinal

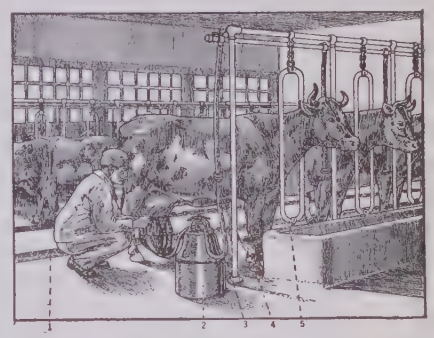
excreta of human beings, because they may contain the microbes of disease even though they come from apparently healthy persons. The well should be located as far as is convenient from the privy or cesspool and so that the natural drainage, if it can be determined, is away from and not towards the well. Furthermore, the sides of the well should be of tight construction so that no water can enter it except from the inlet at the bottom. The top should be water-tight so that no surface wash or drainage can seep in. If the soil is sandy and free from cracks or fissures, surface or ground water will be effectively filtered and rendered safe before it reaches the water level at the bottom of the well.

Protecting Large Water Supplies. The existence of large communities is impossible without a sufficient supply of water of good quality. It is therefore essential that artificial reservoirs be built for towns and cities if a natural supply such as a river or lake is not available. Man is always careless about the disposal of his wastes. No large body of water can be considered safe for consumption in its natural state even though the population near or upon the area from which it drains is small. Sewage pollution may enter it, regularly or occasionally, and large epidemics may follow. There are three general methods of safeguarding a water supply: (1) storage, (2) filtration and (3) disinfection.

Purification of Water by Storage. If water is stored for a considerable period of time (two, three or more weeks) such disease bacteria as gain entrance to it will usually die out for lack of food. This is one of the reasons for the building of large storage reservoirs, built by impounding a natural drainage or by pumping water into a specially constructed, large tank. The water need not be actually stored for a long time. It is frequently sufficient that the dimensions of the reservoir be ample so that the regular draughts made upon it result in such a slow flow through it that each portion of water is several weeks in passing through from the inlet to the outlet.

Purification by Filtration. Sanitary engineers have found that storage is frequently impractical because the locale does not make the building and protecting of a reservoir convenient or economical. Unusual draughts may be made upon a reservoir, particularly in times of low water, and water may be consumed that has not been stored sufficiently to have been completely purified. Filtration through sand is then the common resort for the more certain purification of water. This is usually accomplished by building large underdrained beds of carefully chosen sand. In passing through such beds ("slow sand filters") practically all of the bacteria adhere to the surfaces of the sand grains. The water flowing off through the drains below may be nearly sterile. Where the appropriate



Water Purification

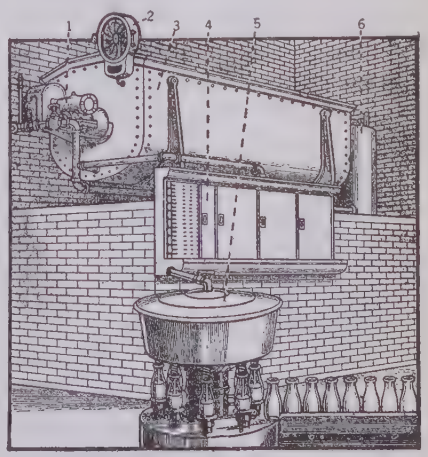
kind of sand is not available, where the water contains finely suspended clay, or for large cities where an ample area of sand beds cannot be built, engineers frequently add a "coagulant" to the water and then remove this and adherent bacteria from the water by rapid filtration through mechanically washed filters ("rapid" or "mechanical" filters.)

Purification by Disinfection. As a final protection of the water supply, practically all progressive communities use disinfection whether or not storage or filtration or both are also used. The cheapest and most reliable methods depend upon the use of chlorine or a chlorine yielding substance like calcium hypochlorite. Added in quantities of a few tenths of a part per million parts of water, chlorine will destroy all of the important disease germs of the kinds that may gain access to water. Among others, the bacteria of tuberculosis, typhoid fever, dysentery and cholera are destroyed by chlorine. It will not destroy the spores of certain pathogenic bacteria (see p. 997), but these are not commonly present in water and are not ordinarily dangerous when ingested.



Milk Supply. Second to water in importance, milk is an item of diet that requires special sanitary precautions in its production and distribution. Milk is a nearly perfect food for microbes as well as for man. Disease

Model Dairy Barn
Healthy cattle and a sanitary dairy barn are the starting points in the production of clean milk: 1. Cleaning trough; 2. Milking machine; 3. Compressed air-pipe; 4. Individual drinking cup for cows; 5. Movable stanchion.

germs as well as harmless varieties can use it as a food and may multiply in it so that the individual ingesting it without its having been heated or cooked may receive a large infecting dose. Epidemics of typhoid fever, scarlet fever, diphtheria, septic sore throat, Malta fever (also known as undulant fever) and other diseases have frequently been caused by infected milk. To safeguard the milk supply, sanitary precautions are essential at many stages in its marketing.

The first requisite in producing a safe milk is that it should come from cattle that are

Pasteurizing Milk
Showing a unit of a pasteurizing plant: 1. Mechanism for turning coils; 2. Recording thermometer; 3. Tank for heating; 4. Cooling coils; 5. Automatic bottler and capper; 6. Storage tank.

free from disease. In progressive communities, inspectors examine the cattle at frequent intervals to detect those which have tuberculosis or disease of the udders. The farmer and milker must also watch the cattle closely for infections that may develop between inspections. Diseased cattle must be separated from the healthy ones and eliminated from the dairy herd. In addition to inspection of

the animals, strict ordinances must be observed concerning the health of the milker, the cleanliness of the dairy barn, the thorough cleansing and disinfection of all the milking and storage utensils. In a modern dairy, milking is done by sterilized milking machines and the milk is promptly cooled to prevent the development of such bacteria as may be present in the milk. The milk is then conveyed by rapid transit to the dairy or to the pasteurizing plant where it is tested for its content of butter fat, water and so forth.

Pasteurization of Milk. No matter how carefully precautions are observed to obtain milk from healthy cattle and to reduce the opportunities for contamination and the development of bacteria, raw milk cannot be considered safe for consumption. Infection will occasionally get in and may cause disease.

Sewage Disposal
A "sprinkling filter" for sewage disposal.

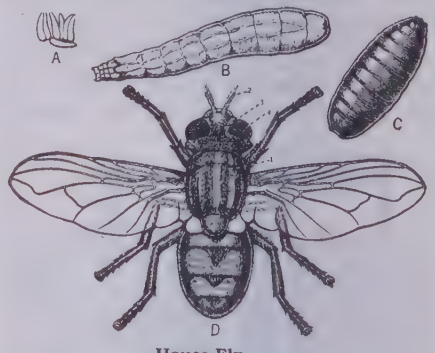
Pasteurization, named after Louis Pasteur, is the only effective safeguard (see page 1009). It consists in heating the milk at a temperature of 140° to 145° Fahrenheit for from twenty to thirty minutes. All disease germs of the kinds that may be present in milk are destroyed. The milk should then be cooled promptly to approximately 40° F. and kept cold until consumed. Pasteurization does not destroy all bacteria and if pasteurized milk is not kept cold it will turn sour and spoil. Properly pasteurized milk is pasteurized in the bottle or is bottled by automatic machinery as it flows from the pasteurizing chamber through the cooler to the bottler.

Sewage Disposal. It is not sufficient that a community protect its water and milk supplies. It should make adequate provision for the proper disposal of its sewage and garbage. In getting rid of its sewage it is important to avoid offensive sights and smells and to avoid the contamination of the community's water and food supplies and those of its neighbors.

Disposal by Dilution. The simplest method of disposing of sewage is by dilution into the nearest large body of water. The natural processes of oxidation and bacterial action convert the putrescible and offensive matters into stable products. It is essential, however, that the discharge be into an adequately large body of water and be sufficiently distant from water supply intakes, bathing beaches and oyster beds.

Disposal by Filtration. It is frequently impractical to dump sewage into a nearby body of water. For a rural household or a small community it is sometimes sufficient to treat the sewage in a septic tank and permit the out-flowing fluid (*effluent*) to drain away through the soil. Bacterial action in the tank stabilizes the offensive and unstable organic matter. For large communities there are many devices available for sewage treatment. If the community wishes to, or if it must, it can convert its sewage into a clear, sparkling water, but the process is usually very expensive. Each community must adapt its sewage treatment program to its own problem. In some places treatment in large septic tanks of suitable design (Imhoff tanks) with or without preliminary screening to remove coarse detritus and suspended matter is sufficient. In others it is necessary to filter sewage through properly constructed filter beds. These are usually beds of stone and gravel, several feet thick and rather large (from one-quarter up to several acres in area), over which the sewage is sprayed. The spray absorbs the oxygen, and on the surfaces of the gravel and stones oxidizing bacteria grow, form jelly-like coatings, and work upon the organic matter in the sewage so that a highly purified effluent is all that flows from the bed. This may be emptied into a stream or other body of water without causing serious harm or nuisance.

Garbage and Waste Disposal. Towns and cities must also make adequate provision for the proper disposal of their solid wastes, garbage, ashes and rubbish. In up-to-date communities closed or carefully covered, water-tight wagons or carts are used to haul the material away at frequent intervals.



Garbage Removal
The garbage is being removed by means of a properly constructed wagon which is of steel and water-tight.

This is done so that breeding places for insects do not accumulate and offensive sight, smells and drippings in the streets and roads are not produced. At the place of disposal, the modern cart can be dumped and washed automatically. Dumping in open places frequently leads to the establishment of serious nuisances. Garbage can be safely and profitably fed to hogs. Large cities must commonly use other methods. In some places incineration is used, and the ash and clinker that is left is used to fill in vacant land or water-fronts. In others, devices are used by which the water, grease and solids are disposed of separately. The grease is often valuable for commercial purposes. This process is called "reduction."

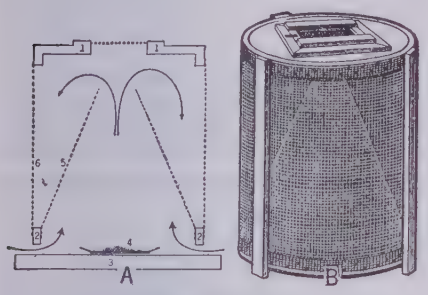
Insects and Other Carriers of Disease. The rôles which insects play in the transmission of disease has been mentioned elsewhere (p. 1004). The control of insects is as largely one of municipal as of domestic sanitation. It is important that each household play its part in combating these winged enemies of man, but concerted action of the community is also essential. Some insects are only accidental, adventitious or mechanical carriers of disease germs, such as the housefly, which may carry typhoid; others are specific carriers of particular diseases, the spread of the disease being unusual or impossible without them, an example of which is the mosquito and malaria.

Flies. The part played by the common fly (the house fly), *Musca domestica*, is dependent upon its breeding and feeding habits.

House Fly
The life cycle of the house fly, *Musca domestica*. A, eggs; B, larva; C, pupa; D, adult: 1. Broad longitudinal stripes; 2. Arista; 3. Simple eye; 4. Compound eye.

The mother fly lays her tiny white eggs on manure, garbage or other refuse or filth. From each egg hatches out a small, white maggot (larva). This grows for four or five days and then burrows down into the ground where it changes into a brown, motionless, resting body (pupa). After four or five days, the adult fly hatches out and takes to the air. The fly breeds in filth and feeds on filth. It also comes to the kitchen and the table; it alights on food or on the body. From filth to food or the body, it carries germs and leaves them where it alights and rests. It frequently carries typhoid bacilli and other disease germs from excreta to food and drink.

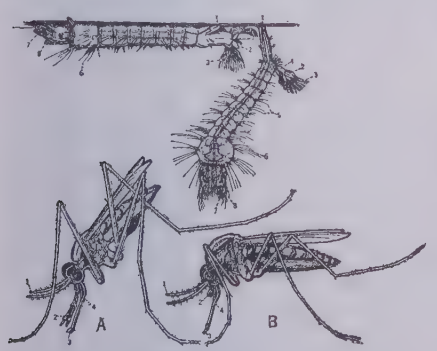
An understanding of these facts is essential in attempting to control flies. First, their



Fly Prevention
Covered manure bins are necessary to prevent flies from breeding.

breeding must be prevented by keeping manure, garbage, refuse and all kinds of decaying matter in tight covered containers so that flies cannot gain access to deposit their eggs. Second, flies must be trapped where they are present in large numbers, particularly if near the home. Suitable and effective flytraps can be built easily and cheaply.

Third, it is essential to keep the house and privy carefully screened so that the flies that are about cannot enter the house.



Mosquitoes. These insects are the most dangerous of all to men, especially in warm places, because they are the specific carriers of malaria (see page 1004). Like other insects, the mosquito goes through four phases in its life history: egg, larva, pupa and adult. The

A Simple Fly Trap

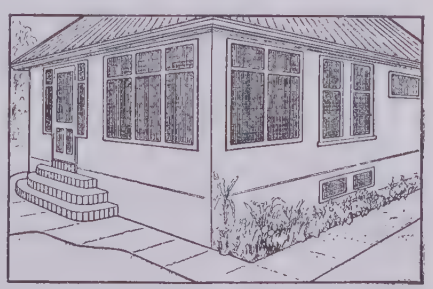
At left is a section of a fly trap to show construction. At right is an external view of the fly trap: 1. Wooden top; 2. Wooden hoop to which screenwire is attached; 3. Table top; 4. Saucer of sugar or other bait; 5. Inverted cone with apex left open; 6. Cylinder of screenwire.

eggs are laid in stagnant or slow-moving water, small pools or ponds, ditches, sluggish streams clogged by plant growth, marshes, tin cans, roof gutters and almost any collection of exposed water. The larva or wriggler, so-called because it moves about by jerks, hatches out from the egg. It obtains its air by frequently coming to the surface to breathe. To accomplish this it sticks the breathing tube in its tail up through the surface. A few days later the larva changes to the pupa and from this the winged adult hatches out. The common mosquito (*Culex*), which is a nuisance but which is not ordinarily capable of carrying malaria, can be distinguished from the more dangerous malaria mosquito (*Anopheles*) particularly in the larval and adult stages. When the larva

Mosquitoes

The larval (upper) and adult (lower) stages of Anopheles (A) and Culex (B) mosquitoes. The larvae: 1. Breathing spiracle; 2. Anal gills; 3. Ventral brush; 4. Anal segment; 5. Abdominal lateral tufts; 6. Thoracic hair tufts; 7. Mouth brushes; 8. Antennae. The adults: 1. Antennae; 2. Palpi; 3. Labellae; 4. Labium.

comes to the surface to breathe, it hangs down from the surface if it is *Culex* and lies flat against the surface if it is *Anopheles*. (The former has a longer breathing tube than the latter.) The adult *Culex* has shorter legs than the adult *Anopheles*, so that when standing quietly the *Culex* is in a hunchbacked position (head, thorax and abdomen not in a straight line) whereas the *Anopheles* is at an angle to the surface on which it is resting and the body is straight (head, abdomen and thorax in a straight line).

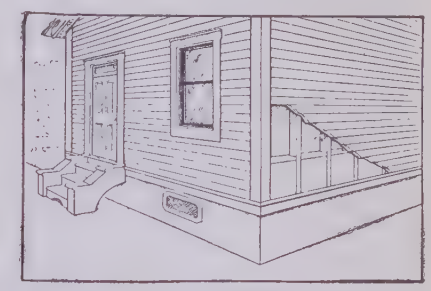


The control of mosquitoes is based upon the same principles that apply to the control of flies. First in importance is elimination of breeding places, wherever this is feasible and practical. This necessitates draining swamps, pools and other collections of stagnant water in the vicinity of habitation. Second is the destruction of the larvae by covering with a thin film of kerosene or other oily material

Mosquito Prevention

The drainage of swamps for the prevention of mosquito breeding.

the surface of all stagnant water that may serve as a breeding place. As the material spreads over the surface of the water it forms a film through which the larva cannot thrust its breathing tube when it comes up to breathe air. Third is the careful and thorough screening of all windows, doors and vents of the house with a fine-mesh wire or cloth net. In addition, in the control of malaria there is a fourth method which applies to the microbe of disease rather than to the insect; this method is the use of quinine taken by

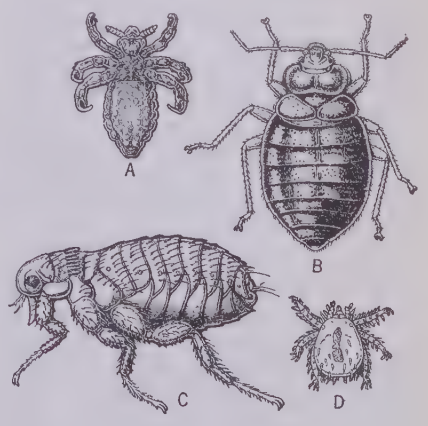


Insect Exclusion

Screening of doors and windows for mosquito and fly exclusion.

mouth to prevent or cure malaria. Quinine is a medicine which is a specific poison for the protozoan which causes malaria. In warm countries where malaria is prevalent, quinine should be taken regularly by all persons who are infected or exposed to infection.

Rats, Fleas and Plague. Among the many other diseases of man that are spread by insects, brief mention may be made of plague (bubonic plague). This is the Black Death which, in earlier centuries, used to sweep through countries like a terrific scourge. In one epidemic it killed between a quarter and a half of the entire population of Europe.



It is known that plague is primarily a disease of rats and other rodents. It is spread from rat to rat and from rat to man by the rat flea which, as it bites and sucks the blood of a diseased animal, receives a supply of the germs (*Bacillus pestis*) and then passes them on to the healthy animal or man that it bites

Rat Proofing

The filling of wall spaces with cement to exclude rats.

later. The effective control of this disease depends upon destroying and eradicating rats, and upon preventing them from breeding in and about the living-quarters of man. To accomplish these ends, houses and barns should be built or made rat-proof by the screening of all openings near the ground, by building tight foundations and by pouring cement between the joists to sufficient depth so that the rats cannot gnaw their way through. Collections of garbage and refuse should be kept in closed containers. It is especially important that granaries be kept in rat-proof condition. To prevent the importation of infected rats and their fleas from other countries of the world, especially from countries where plague is prevalent, incoming ships are fumigated to destroy rats, and the mooring lines are protected with large, metal collars so that escaping rats which attempt to come ashore on the lines cannot pass.

Some Insect Parasites

A. Body louse, *Pediculus vestimenti*; B. Bed bug, *Cimex lectularius*; C. Rat flea, *Ceratophyllus fasciatus*; D. Jigger, *Chigger*.

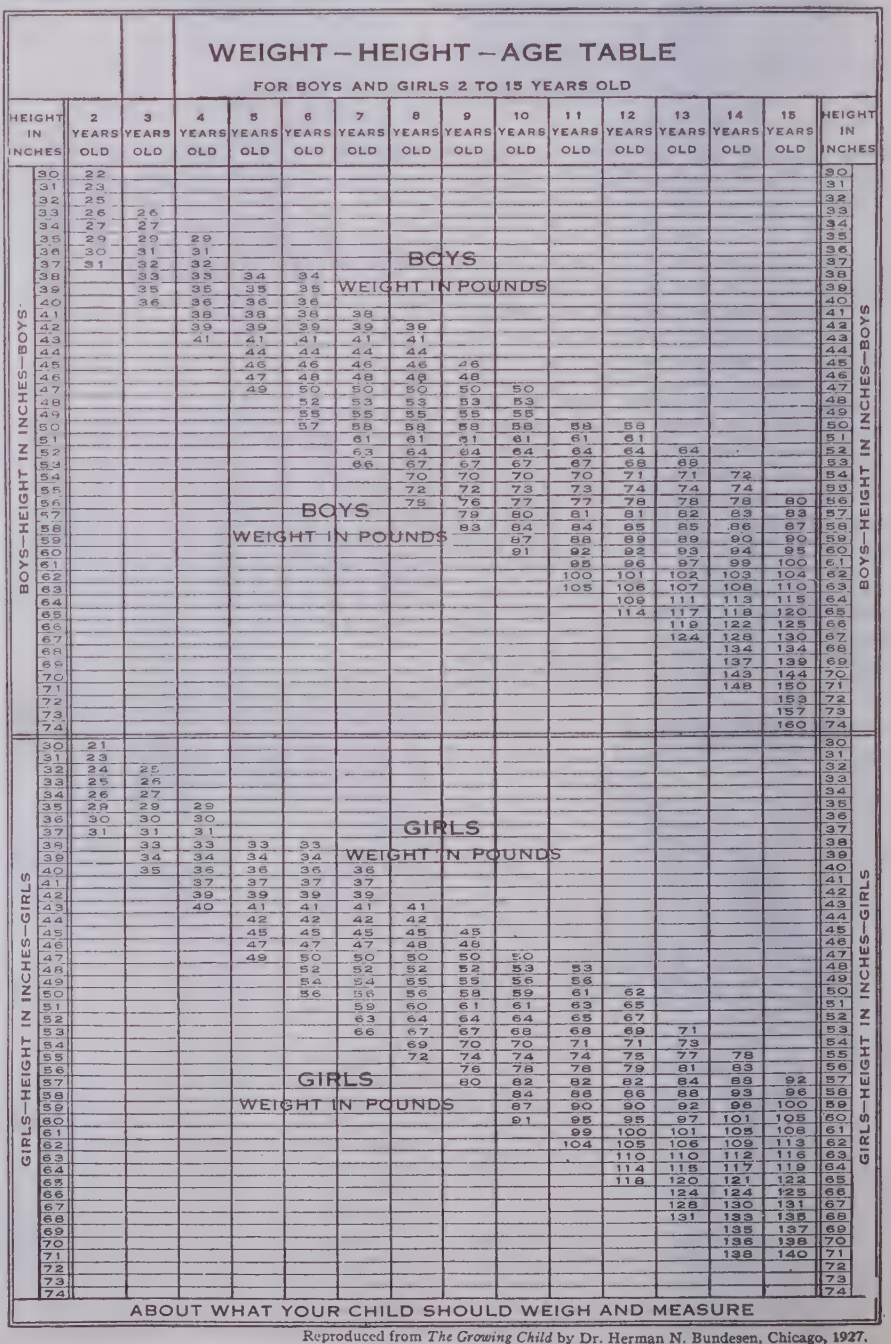
Other Diseases Spread by Insects. There are many other diseases which are regularly or occasionally spread by insects. Typhus fever (ship, jail, camp fever) is spread by the bite of the body louse. Improvements in personal cleanliness have resulted in the

practical control of this disease by the elimination of lice. When the practice of cleanliness breaks down, as in time of war, typhus fever usually takes its toll of health and life.

Certain kinds of mosquitoes are responsible for the spread of yellow fever, filariasis and dengue fever in parts of the world where these diseases occur. Tsetse flies are chiefly responsible for the spread of sleeping sickness in Africa. A particular kind of blood-sucking fly (*Chrysops*) spreads the germs of tularemia, a disease which occurs in the United States in wild rabbits and other animals, and which is occasionally contracted by hunters and by persons who handle infected rabbits. Some kinds of ticks carry the germs of Texas fever of cattle and Rocky Mountain spotted fever in the United States and of relapsing fever of Africa. It is not entirely certain, but it is suspected, that various bedbugs are partly responsible for the spread of tularemia in the United States, European relapsing fever, Indian kala-azar and South American trypanosome disease. In addition to typhus fever, lice are known to spread trench fever, and Asiatic, European and Algerian relapsing fevers.

Health Departments and Public Hygiene. Sufficient evidences have been given that personal and public hygiene are intimately interrelated. There can be no healthy community without healthy individuals. The practice of personal hygiene devolves essentially upon the individual, but the individual cannot entirely safeguard his personal health except by concerted and coöperative action with other individuals. Many problems of sanitation, like those associated with water supplies, sewage disposal and the control of insects, are clearly community problems. In addition, there are many others with which the individual cannot cope single-handed. The proper care, treatment and prevention of disease requires the availability of hospitals, clinics, sanatoriums and other types of organizations, the provision of laboratories to aid in the diagnosis of disease, the supervision of food supplies and of food-handling establishments, the provision of statutes concerning disease prevention and of means for their enforcement, the maintenance of staffs of experts on sanitary building design, ventilation, industrial hygiene, school hygiene, the provision of physicians and nurses in the examination of school children, and many other community organizations. Finally, experience has demonstrated that common welfare requires that there be available experts in the public teaching of hygiene so that the fruits of discovery and invention in medical and related subjects shall be carried to the public and made available for effective utilization. To these ends modern urban and rural communities arm and equip themselves with health departments.

The organization of a health department depends upon the size and nature of the community. In American cities, the department is usually under the direction of a commissioner of health who is appointed by the mayor or other chief executive officer. The commissioner of health usually operates with the advice and approval of a board of health.



Under a commissioner of health most commonly the bureaus are those concerned with:

(1) Communicable diseases,
(2) Sanitation (water supply, sewage disposal),
(3) Laboratories (diagnosis of disease, distribution of antitoxins, vaccines),
(4) Child, maternity and school welfare,
(5) Food and drug inspection,
(6) Public health nursing,
(7) Public health education,
(8) Vital statistics.

In some places these functions are divided among more, and in other places they are combined in fewer, bureaus.

City departments of health are in a measure supervised and their activities are coördinated by state departments of health. The health problems that concern the mutual relations of the state and inter-state traffics are supervised by the various departments of the federal government, chiefly the United States Public Health Service of the Treasury Department, although the Departments of Agriculture, Commerce, Labor, Interior and other Departments each performs important public health functions.

The Trend of the Public Health. There is no doubt that the general trend of public health has been decidedly towards improvement. To be sure, there are still great epidemics of disease that sweep through the population, as witness the epidemic of influenza of 1918-1919; but many diseases have been so effectively controlled that some which were common a century ago are now rare,

Reproduced from *The Growing Child* by Dr. Herman N. Bundesen, Chicago, 1927.

and a few are rapidly approaching extinction. More than one-third of the illness that disabled man and a third of the deaths of persons who went to their graves prematurely, have been prevented in half a century. It cannot be said that the ultimate span of life has been changed: man still does not often exceed a hundred years of life. But the average length of life has been increased from something like thirty-five to approximately fifty-five years in communities which are progressive in the practice of sanitation and hygiene. These accomplishments have been due particularly to the revolution effected in medical science by the germ theory of disease, improvements in standards of living and by mechanical and industrial applications of chemical and physical science. One of America's greatest leaders in public health (the late Dr. Herman M. Biggs) said: "Public health is purchasable. Within natural limitations a community can determine its own death rate." And the Department of Health of the State of New York adopted these as its watchwords.

In the following tables and paragraphs appear some vital statistics for the United States to indicate more precisely some facts about births, infant and adult mortality.

VITAL STATISTICS

It will be observed from the table of figures that in 1926 (the last year for which full official figures are available) there were something over 1,200 deaths in each 100,000 persons in that portion of the United States for which records are available (the Registration Area for Deaths—including 90 per cent of the country's population). Of this total mortality, more than 960 deaths in each 100,000 persons (approximately 80 per cent of the total) were due to fifteen causes of death.

Death Rates per 100,000 Estimated Population in the United States: 1926

(Arranged in order of importance)

	All Causes	1222.7
1.	Diseases of the heart	199.1
2.	Influenza and pneumonia	99.3
3.	Acute and chronic diseases of the kidneys	98.3
4.	Cancer, etc.	94.9
5.	Diseases of the brain, etc.	89.0
6.	Tuberculosis (all forms)	87.1
7.	Diseases of early infancy	71.5
8.	External causes (other than suicide, homicide and automobile accidents)	60.7
9.	Bronchitis and broncho-pneumonia	50.5
10.	Intestinal diseases (diarrhea, etc.)	33.6
11.	Diabetes	18.0
12.	Automobile accidents	17.9
13.	Unknown or ill-defined diseases	17.8
14.	Appendicitis, etc.	15.0
15.	Suicide	12.8
	Total for fifteen named causes	965.5

These figures have been compiled from the report of the U. S. Bureau of the Census, *Mortality Statistics* (1926, Part II, p. 39).

It is illuminating to study the data in this brief compilation. The striking facts are that diseases of the heart are, by a considerable margin, the principal cause of death; influenza and pneumonia come second; diseases of the kidneys, third; cancer, fourth; and so on. Figures of this sort are sometimes analyzed by considering groups of causes of death. Thus, items 1, 3, 4, 5 and 11—representing causes of death that are called the "degenerative" diseases, principally because they usually occur late in life and are concerned with the break-down of tissues or organs—were responsible for a combined death rate of approximately 500 deaths per 100,000 persons (over 40 per cent of the total mortality); items 2, 6, 9 and 14—fatal infectious diseases—accounted for 250 deaths in each 100,000 (about 20 per cent of the total); and items 7, 8, 10, 12, 13 and 15—the remaining principal causes in this list of 15—caused over 200 deaths per 100,000 persons (something over 17 per cent of the total).

This type of analysis is somewhat fallacious because it presumes that the degenerative diseases can be set apart from the infectious diseases. It may be that cancer is not caused by parasites and is not infectious. It is not inconceivable that certain diseases of the brain, heart, arteries, kidneys and so forth, are not infectious. But there is not the slightest doubt that a large fraction, perhaps most, of the fatalities caused by these "Hosts of Death" are definitely bacterial infections.

It is of interest to comment on the fact that many of the diseases which were listed earlier among the principal communicable diseases are not among the fifteen principal causes of death. This is in part a reflection of the fact that many of the commonest diseases are mild and non-fatal; that when they are severe they are most dangerous not because they themselves kill, but because they lead to secondary diseases (like broncho-pneumonia and nephritis) which are deadly; and that many of them (like typhoid fever and diphtheria) have been extensively controlled and reduced.

In thirty-five States, the District of Columbia and the Virgin Islands, the recording of births was sufficiently accurate in 1927 so that these communities were included in the Birth Registration Area of the United States Bureau of the Census. In that year (the last for which official statistics are available in final form) the area included 104,000,000 persons (87 per cent) of the 119 millions in continental United States. In the area there were recorded in 1927, 2,137,836 live births or 20.6 per 1,000 population. In the same period there were 1,176,805 deaths in the same population (11.4 per 1,000 population). The birth rate exceeded the death rate by 81 per cent of the latter, indicative of an extremely high state of national vitality. There were 82,931 stillbirths (3.9 per 100 live births) and 138,017 infant deaths (64.6 per 1,000 live births). The infant mortality rate (64.6) has been declining very rapidly in recent years and is the most certain sign of the application of medical, educational and public health knowledge to the conservation of human life. Not more than fifteen years ago rates of infant mortality of from 125 to 175 (infant deaths per 1,000 births) were not uncommon. Infant mortality has been cut in half and improvements are still occurring.

The principal causes of infant deaths are (1) infectious diseases of the respiratory tract, (2) disorders of the intestinal tract (largely infectious) and (3) conditions concerned with defects in the development of the child's body, accidents and injuries of birth and so forth. A decade ago approximately one-third of all infant mortality was caused by each of these groups of causes. The reductions in infant mortality that have been effected have, however, been almost entirely in the first and second groups. Consequently, group (3) is now responsible for a relatively increased proportion of infant deaths. Thus in 1926 diseases of group (1) (respiratory) were responsible for 25 per cent, group (2) (intestinal) for 18 per cent, and group (3) (congenital) for 57 per cent of all infant deaths.

TABLES OF FOOD VALUES

At least one food from each of the three groups should be in each meal every day.

Name of Food	Measure	Wt. Oz.	Total Calories	Group I—Protective Foods: Vitamin A — Gives Strength, Aids Growth, Prevents Some Eye Diseases And Builds Resistance	Vitamin B — Builds Appetite, Helps Growth, Prevents Beri-Beri	Vitamin C — Builds Health, Prevents Scurvy	Vitamin D — Makes Strong Bones, Prevents Rickets

Use at least one-half pint of milk daily for each adult, and a pint for each growing child.
In addition to potatoes, serve daily one green vegetable, a salad and fruit in some form.

Use the chart in selecting those foods which will supply all the needed elements, giving preference to those marked "XX" or "XXX"

Reproduced from *The Growing Child* by Dr. Herman N. Bundesen, Chicago, 1927.

THE meaning and scope of physical education have changed greatly in recent years. When gymnastics and calisthenics were introduced into this country they formed a large part of our programs of physical education. However, these forms of exercise failed to meet the needs and interests of our American youth, and as a consequence attention gradually turned to games and sports to satisfy the desire for team play and the spirit of competition. During the World War, participation in sports events received a great impetus. The government placed major emphasis on games and sports and minor emphasis upon calisthenics and setting up exercises. Boxing, wrestling, football, baseball and other athletic activities were promoted in all the military training quarters. After the war, schools and colleges took up athletic games with a new interest. In recent years much has been done through the building of gymnasiums and stadiums as well as through the adding of more recreational activities to the physical education programs.

Physical education, as it is carried on in our schools, consists of baseball, basket ball, football, hockey, winter sports, water sports, camping and hiking, track and field events. These various activities are later described in detail (pp. 1019-42).

Much emphasis is being placed upon the educational values of physical education, and chief among these is sportsmanship. There is no better place to inculcate the ideals of being a true sport than on the athletic field. Almost every school or college now has its code of sportsmanship, and coaches and teachers of physical education are constantly keeping before boys and girls the ideals of this virtue.

The Sportsmanship Brotherhood, which devotes its work to the promotion of better sportsmanship, is aiding many schools and colleges in carrying out its code through chapters formed among student bodies.

THE CODE OF SPORTSMANSHIP

KEEP THE RULES.
KEEP FAITH WITH YOUR COMRADE.
KEEP YOUR TEMPER.
KEEP YOURSELF FIT.
KEEP A STOUT HEART IN DEFEAT.
KEEP YOUR PRIDE UNDER IN VICTORY.
KEEP A SOUND SOUL, A CLEAN MIND AND A HEALTHY BODY.

PLAY THE GAME.

Playing according to the code of sportsmanship will aid in building character, and this, in turn, is an important part of citizenship.

The program of intramural sports has developed in recent years in most of our grammar schools, secondary schools and colleges. It calls for the participation of all students in various athletic activities. It is typified by such slogans as "sports for all," "every student on a team," "everyone in a game" and "year round activity for all." Intramural activities in the various games and sports are carried out through interclass games. This system gives all, not only the few who are more skilled, a chance to learn and to play the various games.

It is the aim of physical education to urge everyone to participate in a game for the pleasure of the activity alone and its social benefits. This aids in the fostering of the spirit of amateurism. An amateur sport, according to the Intercollegiate Association of Amateur Athletics of America, is one "who engages in sports solely for the pleasure and physical, mental or social benefits he derives therefrom and to whom sport is nothing more than an avocation."

Swimming in Camp

The director is instructing the boys in swimming and in the principles of life-saving.

An important phase of the physical education program is that of tests. A few of the common tests are described here and can be used as a part of the physical education program of our schools.

ATHLETIC BADGE TESTS FOR BOYS AND GIRLS

It is always a challenge to one's "desire to win" and "spirit to conquer," to endeavor to meet the mark set by somebody else or to make a new record of one's own. Realizing this tendency the Playground and Recreation Association of America has for a long time promoted athletic tests which serve as a measure of skill in various athletic events. These tests are divided into three groups. Boys and girls of twelve years should be able to pass the first group of tests, those of thirteen years of age should be able to pass the second, and boys and girls in high school should be able to pass the third group of tests. There is no age limit. Any boy or girl may enter them alone or in a group. They are based upon fundamental skills in the physical education activities of climbing, running, jumping and throwing and have been built on these fundamental activities. In order to pass one group of tests it is necessary to meet the set requirements in four of the events, one from each of the four classes, such as climbing, running, jumping and throwing. Spiked or plaited shoes are not to be used, but ordinary tennis or gymnasium shoes are permitted. The tests are slightly different for boys than for girls. They have been carefully worked out so as to meet physiological differences of boys and girls as well as to satisfy their varied interests in certain activities. Attractive badges for boys and for girls are prepared for those who pass the three tests. These badges may be secured from the Playground and Recreation Association of America when the tests are taken according to regulations.

Athletic Badge Tests for Boys. *First Test.* The tests for boys are based upon the fundamental physical activities of running, jumping, climbing and throwing. They take into account the physical ability of the boys at the respective age levels. The first of this group of tests has two options. It consists of either the pull up (chinning) four times or of climbing a rope, using both hands and legs, to a height of twelve feet. A portable chinning bar may be erected in an ordinary doorway or the horizontal bar in the gymnasium or even the rungs of a ladder set at an angle against a building may be used. The rope, in the rope climbing event, is to be one and one-fourth inches in diameter, with points marked on it with white or colored string or cloth, at the twelve-foot height and the sixteen-foot height. The start should be made from a standing position without jumping up a part of the way.

The second test of this group is the standing broad jump. The required distance is five feet nine inches. It is advisable to have a jumping pit to land in. This can easily be made by digging up the ground with a spade and raking it down until it is soft and smooth. There should be a wooden or metal

strip two inches by five inches imbedded in the ground to use as a "take-off." In the standing and running broad jump the toes must not project over the front of the take-off or touch the ground in front of it. This is called a "foul" and counts as a trial.

In the third test of this first group there is the choice of running the sixty-yard dash in nine seconds, or running the fifty-yard dash in eight seconds. In all of the running events it is desirable to have a stop watch in order to be accurate in keeping records. Judges are necessary in order to make the tests accurate.

In the fourth test of this series there is the choice of throwing a baseball for accuracy or for distance. To throw for accuracy it is necessary to throw three strikes out of six throws. The target is to be at a distance of forty feet and should be fifteen inches by twenty-four inches; it may be of wood or of canvas. This area represents the space of the plate which is called a "strike." The target should be suspended a few feet away from the backstop or the fence against which the balls are thrown. The lower edge of the target should be twenty-four inches from the floor. Correct pitching position should be maintained in throwing for the target. The playground ball may be used instead of the official league ball if the standard distance is maintained. Instead of throwing for accuracy the contestant may throw the same ball for distance, the requirement being one hundred thirty feet.

Second Test. In the first of this group of four tests the contestant may either do the pull up (chinning) six times or climb the rope, using both hands and legs, to a height of sixteen feet.

In the second of this group there is the choice of the standing broad jump for a distance of six feet six inches, or the running broad jump for a distance of twelve feet.

The third test of this series gives the contestant the choice of running the sixty-yard dash in eight seconds, or the one-hundred-yard dash in thirteen and two-fifths seconds.

In the fourth test of this group there is the baseball throw for accuracy, three trials out of five throws at a distance of forty-five feet, or the baseball throw for a distance of one hundred ninety-five feet.

Third Test. The contestant, in the first of this group of tests, may choose between the pull up (chinning) nine times, or climb the rope to a height of sixteen feet, using hands only.

In the second test he is given the choice of the running high jump of four feet four inches or the running broad jump of fourteen feet. In the high jump a thin stick (commonly a fishing pole) is used as the bar over which to jump. When the bar is knocked off it counts as a trial. The height is to be measured from the middle of the bar to the ground which, of course, should be level. Three trials are permitted at each height.

In the third test of this group the contestant may run two hundred twenty yards in twenty-eight seconds or the one-hundred-yard dash in twelve and three-fifths seconds.

In the fourth test there are three choices: the baseball throw for accuracy, throwing three strikes out of five throws at a distance of fifty feet, the baseball throw a distance of two hundred twenty feet, or the eight-pound shot put a distance of twenty-eight feet. A lead or iron shot, if the weight is correct, may be used. A seven-foot circle is used from which the shot is put. If the foot touches outside of the circle during the act of putting, it is a foul and the trial is lost. The farthest distance in three trials should be recorded.
